Sapper T. T., wounded on July 31st, was admitted, under the care of Major Moffat, on August 1st. He stated that he did not lose much blood after being wounded, and that no tourniquet was applied. There was an entry wound on the outer side of the left knee-joint, level with the lower end of the patella and situated over the biceps tendon; there was no exit wound. There was copious effusion into the knee-joint, and a systolic bruit could be heard in the popliteal space. The posterior tibial and dorsalis pedis could be felt pulsating. On August 5th the leg was oedematous. He had "pins and needles" in the foot, and there was an extensive area of loss of sensibility, as shown in Fig. 6. The gastrocnemius and soleus were active, and there was perhaps the slightest amount of activity in the tibialis anticus; but with these exceptions there was absolute paralysis of all muscles below the knee.

The knee-joint was needled and dark blood withdrawn; the pathologist (Captain A. W. Stott) reported: "No increase of polymorphs. No organisms seen."

On August 6th the popliteal artery and vein and the anterior and posterior tibial arteries were ligated. The artery had been wounded at its bifurcation. The resulting arterial haematoma communicated with the knee-joint through a rent in the posterior part of the capsule. The internal and external popliteal nerves were seen to be uninjured. On August 7th some recovery of sensation on the dorsum of the foot was noted, but sensation was still absent from the sole. Sensation in the left foot had completely returned on August 8th, and all movements had returned, though the muscles previously paralysed were still weak. By August 13th the muscles had recovered almost completely, and their contractions were strong, except that some weakness remained in the gastrocnemius and soleus. This weakness may have been reflex in origin, being merely an unconscious attempt to maintain rest in the popliteal region.

FIG. 6 (Case VIII).—The shaded area represents loss to light touch; 2 is the upper boundary of loss to light pressure; 3 the upper limit of loss to pin-pricks.

CASE IX.

Lieut.-Cpl. H. W., wounded on August 5th, was admitted on the following day. There were small entry and exit wounds in the left arm, on the inner side, just above the elbow. The projectile had passed in an antero-posterior direction close to the bone. He said that he lost a great deal of blood when he was hit—the blood “pumped out.” A tourniquet was applied over the wound, and not removed until about one and a half hours later.

FIG. 7 (Case IX).—The shaded area represents loss to pin-pricks and light touch. The dotted area marks a partial loss of sensation to pin-pricks. The wounds of entrance and exit are indicated by small circles.

The interesting point in Case IX is that the anaesthesia extended far above the level of the vascular and nerve injury. We may explain the phenomenon by referring it to a “functional” origin, if that is any explanation. Or we may regard the condition as being reflex in nature, but we can hardly attribute it to ischaemia.

CASE X.

Cpl. W. J. B., wounded on August 21st, 1917, was admitted, under the care of Captain J. H. C. Fegan, on August 23rd. The note taken on the following day recorded a small entry wound in the left leg on a level with the lower border of the patella and situated on the outer side of the back of the leg just behind the tendon of the biceps. There was no exit wound. The moment he was hit he lost all sensation in the leg, his first thought being that the leg had been blown off. There was considerable oedema of the leg, and he stated that if the leg were allowed to hang down it swelled and became very painful. The muscles did not feel hard. No distinct difference could be felt in the surface temperature of the two feet. An arterio-venous aneurysm had formed in the popliteal region, as shown by a palpable thrill and a loud systolic murmur and venous hum. The posterior tibial could be felt pulsating, but the amplitude of its pulse wave was small and the tension low.

The patient had no “pins and needles” or other subjective sensation in the leg while he was at rest in bed. Sensation to pin-pricks and light touch was lost over an area which, as shown in Fig. 8, extended far above the level of the wound. It

was not complete, for there were areas lower down where both light touch and pin-pricks could be appreciated. The sole of the foot and front of the leg contained such areas. The upper border of the general area of anaesthesia was indefinite, there being a zone in which some pin-pricks were felt, while others were not noticed. The muscles of the leg and foot were parietic, and apart from weak contractions of the gastrocnemius, tibialis anticus, and long extensor of the toes, there was no muscular power in the leg at all. By August 25th the oedema of the leg had disappeared, muscular power had increased, and sensation was returning.

SYMPTOMS.

From these cases it will be seen that the main symptoms are:

1. Subjective sensations in the distal part of the affected limb.
2. Anaesthesia, more or less of the “stocking” or “glove” type, and involving all kinds of sensation, including light touch, pin-pricks, and deep pressure.
3. Muscular paralysis.
4. In certain cases hardness and inelasticity of the muscles.
5. Oedema.

In all of the cases in which no arterial pulse could be felt distally to the injury (I to VIII) the patients complained of subjective sensations, which they described in various terms, but to which we may refer as “pins and needles.” On the other hand, in the two cases (IX and X) in which a distal pulse could be felt there were no “pins and needles.”

In all the cases which were tested except one there was loss of cutaneous sensibility; oddly enough, in the one (Case V) in which sensation was retained (except in the toes, which became gangrenous) there was not only gangrene of the toes, but most extensive myopathy was shown to be present in the muscles of the leg. In the two cases in which a distal pulse could be felt (IX and X), the area of anaesthesia was most extensive, and reached to a level considerably above the wound. In several of the cases the loss to pin-pricks was greater than the loss to light touch.

Motor paralysis was present in all. With one exception, in every case in which no distal pulse could be felt there was a feeling of hardness and inelasticity of the affected muscles which suggested that alterations in their composition had occurred. The exception (Case VIII) was of special interest, inasmuch as the muscular and sensory paralysis rapidly passed away after a wounded popliteal artery had been ligated together with the vein. In the two instances (IX and X) in which sensory and motor paralysis were present, while the distal pulse was not obliterated, the muscles were flaccid and soft, in contrast with the hard muscles felt in the cases of complete arterial lesion.

No case of paralysis was observed as a sequence of injury to the radial, ulnar, anterior tibial, or posterior tibial arteries. In three of the cases in the series (II, III, and V) the wounds were plugged with gauze at the time of the patient's admission to the — General Hospital, and the pressure of this packing may have played a subsidiary part in the causation of symptoms.

It is a little difficult to understand why ligation of an artery in one patient should lead to little or no evil consequences, while in another, seemingly as favourable at the time of operation, grave consequences follow.

Take the following case as an example:

CASE XI.

Pte. G. T. B., wounded on August 22nd, was admitted, under the care of Lieutenant C. N. Longridge, on August 25th. The note from the casualty clearing station was: “Compound comminuted fracture of lower end of left humerus. Brachial artery ligated. Great loss of muscular tissue.”

On admission he presented a through-and-through wound above the left elbow. The original wounds had been excised, and partly stitched over gauze packs. The arm was fixed on a Robert Jones elbow splint. No radial pulse could be felt. There was much oedema of the hand, forearm, and arm.

This case certainly had many of the features which we should regard as favourable to paralysis of vascular origin, for his brachial artery had been ligated, he had a fracture close above the elbow-joint, the wounds were tightly packed, the arm was splinted, and there was copious oedema. Yet there was no paralysis at all. The case is mentioned merely as a contrast with the others and to illustrate the fact that whatever the actual cause of angiotic paralysis may be, it is not clearly defined at present.

PATHOLOGY.

So far these observations have been easier to make than to explain. And the probability is that pathological explanations must remain in abeyance for the present owing to insufficiency of data. Nevertheless, it may be a matter of interest to wander a little into the field of theory.

The attractive and simple course of attributing all the phenomena to ischaemia—to an insufficient supply of blood to the tissues—at once suggests itself, and, if we follow this course, we may describe the symptoms collectively under the title of ischaemic paralysis, and be done with all further speculation. Objections, however, to this title become apparent on close scrutiny. In the first place it involves the acceptance of a hypothesis of causation which at present is not fully established. The symptoms may be due to the small quantity of blood which is circulating, to injury of the sympathetic nerves in the vessel sheath, to the low pressure of the blood stream below the injured artery, to cold, to some other cause altogether, or to a combination of causes. Moreover, although some of the cases just described show that a paralysis similar to the so-called Volkmann's ischaemic paralysis often does follow occlusion of an artery, yet it is clear that this is not the only form of paralysis which may follow a vascular lesion.

For these reasons it appears better to adopt a general title which will not implicate us in any hypothesis other than that the symptoms are consequent upon damage to a blood vessel. Accordingly the term "angiotic paralysis" may be applied with convenience to the symptoms described in these cases.

At the outset we must assume that two factors at least take part in the causation of the symptoms. On the one hand, we may have extensive degeneration of muscle and massive gangrene, without any loss of cutaneous sensibility, except in the area of mortification, while on the other there may be widespread loss of sensation and muscular power without gangrene, without gross myopathic change, and even without obliteration of the distal pulse. From this it is clear that there is no exact correlation between the neuropathic and the myopathic symptoms.

Probably ischaemia is one of the factors, the one which is associated especially with Volkmann's myopathy. In the cases just narrated this condition has been seen only in those cases (i to vii) in which the distal pulse was obliterated, which is significant. If, however, we accept ischaemia as the cause of this myopathy, there must be at least some other cause for the flaccid paralysis and sensory loss which are to be observed after certain vascular injuries in which the artery is not completely divided or obstructed, and in which the distal pulse can still be felt. The fundamental cause in these cases seems to be the actual damage to the arterial wall or to its sheath, rather than any consequent effect upon the supply of blood to the limb. Further, it appears that an incomplete injury—that is to say, an injury in which the artery is not completely severed—is more likely to be followed by extensive sensory loss and flaccid paralysis than is a complete division or ligation of the artery. There is reason to suppose that these symptoms are reflex in nature. Accepting this to be so, we arrive at the following classification of paralysis following arterial injuries:

ANGIOTIC PARALYSIS.

Ischaemia.

Let us consider these two factors in detail. The first is illustrated well by Case v. Here a wound in the popliteal

region was followed by absence of pulsation in the dorsalis pedis and posterior tibial arteries. The foot became cold and white, and remained so for twenty-four hours, at the end of which time there were signs of returning circulation, except in the toes and a small portion of the foot, which became gangrenous. The whole leg up to the knee was slightly oedematous; the muscles were hard and absolutely paralysed. Inspection of the muscles after amputation showed them to have undergone a striking change of colour—they were no longer red, but quite pale and almost buff-coloured. This change affected some of the muscles more than others, and the change was more complete in the distal than in the proximal ends of the muscles. What the actual change and its cause may be we do not know, though the suggestion has been made that it is identical with rigor mortis. Sections of the muscles in this case were made by Captain A. W. Stott, who gives the following report:

Pathological Report.

"Portions of the peronei and gastrocnemius muscles were cut; each showed gross pathological changes. No normal muscle fibres were seen. In sections stained by haemalum and eosin the general impression was that given by an anaemic infarct. The muscle fibres and the interstitial tissues stained a uniform pink. The fibres showed various stages of degeneration—some had almost normal striation but no nuclei; others had completely lost their striation, and appeared as granular masses. Fibres showing different degrees of change were often found next to each other. The majority of fibres appeared swollen. Some were broken up into irregular masses; others were split into longitudinal fibrillae or transverse discs. There was no hyaline degeneration, and no gross fatty change was seen. The interstitial tissue appeared oedematous, stained a faint pink with Van Gieson, and was almost cell-less. There were few capillaries. Throughout the sections there was but little trace of inflammatory reaction. The large vessels, arteries, and veins contained blood, not clot, and appeared normal."

These cases (i to vii) represent the first main variety of angiotic paralysis. The condition is, for the most part, a muscular phenomenon; it is well known as Volkmann's ischaemic paralysis, following especially fractures about the elbow-joint, and may be seen apart from any material sensory defects. The damaged muscles do not recover, and any resumption of function which comes about is attributable to the fact that portions of the muscles, especially the proximal portions, usually escape and are capable of limited activity later on.

Summary Concerning Ischaemic Cases.

1. An arterial injury with obliteration of the distal pulse.
2. Subjective sensation of "pins and needles."
3. Muscular paralysis; the muscles being hard and inelastic to the touch.
4. Anaesthesia of a "stocking" or "glove" distribution, confined to the portion of limb which is distal to the injury, and involving all forms of sensation.

Reflex Paralysis.

The cases (viii to x) in which the paralysis has seemed to be of a reflex nature have the following characteristics:

1. An arterial injury without complete blockage of the vessel.
2. Absence of "pins and needles" sensation.
3. Flaccid paralysis of the muscles which do not feel hard and inelastic.
4. Widespread loss of cutaneous sensibility, extending in two instances well above the level of the wound.

These cases give the impression of being less organic, if one may put the matter in that way, than the ischaemic ones. Case viii showed almost complete recovery within two days of an operation which involved ligation of the popliteal, anterior and posterior tibial arteries and veins. Case x improved up to a certain point with no treatment other than rest in bed. Case ix was not under observation long enough for any improvement to be observed.

The hypothesis that these cases are of a reflex nature

has been adopted partly for convenience of argument, but largely because this explanation seems plausible. The fact that the anaesthesia in two of the cases extended well above the wound has led to the suggestion that it is of a functional nature. But even if we call it functional, does that carry us any further? Several controls have been tried, and patients with fractures, wounded joints, and other bad wounds of the limbs were tested, but in no case was a stocking anaesthesia discovered except in those who had arterial lesions.

Whatever the cause of the paralysis may be in these cases, it can hardly be attributed to ischaemia. In this connexion, it may be well to recall the cerebral disturbances which are apt to follow sudden obliteration, by operation or otherwise, of the lumen of the common carotid or internal carotid artery. These disturbances, severe and not rarely fatal, surely cannot be attributed to ischaemia, seeing what a liberal provision of collateral channels is present for supplying the brain with blood, and considering also the rapidity with which the cerebral symptoms develop.

CASE XII.

Pte. O. K., wounded on September 1st, 1916, was admitted on September 9th. He had been shot through the right neck. He stated that his left arm became paralysed at the instant he was hit; in fact, he thought the wound was in his arm. The projectile had clearly divided the internal carotid artery.

It is difficult to believe, in the absence of better evidence, that such an immediate paralysis could be brought about by ischaemia or embolism of the brain.

GENERAL CONCLUSIONS.

The currents of thought started by these cases are, however, not likely to lead us into any useful channel until we have a great many more clinical records to work upon, together with additional observations, including the electrical reactions of the affected muscles, the deformities produced, and the prognosis. It has not been possible to gather information on these points.

Although the importance of these paralytic effects of arterial injuries cannot at present be estimated, yet, until we are better informed as to prognosis, we may well be more reluctant in the future than we have been in the past to tie a main artery for the arrest of haemorrhage. We shall be more particular and persistent in our endeavours to find the exact source of bleeding, in the hope that it may prove to concern a branch only instead of the main trunk. And, in those instances in which the main trunk itself is wounded, we shall be more disposed to cure the leak by suture of the vessel, or failing this, to attempt an escape from the ill consequences of direct ligation by the temporary use of a Tuffier tube. Furthermore, when we are compelled by the nature of the case to tie a main artery, we shall take care to tie the main vein also; because, as Sir George Makins has pointed out, the results which follow ligation of both vessels are better than those which ensue upon a blockage of the main artery alone.

LITERATURE.

Though there is not much literature on this subject there is enough to give food for thought.

In the first place, the association of so-called ischaemic paralysis, of the type described by Volkmann, with injuries involving complete blockage of an artery, has been recorded by J. G. Sherrill,¹ Carl Hirschmann,² L. Verdet,³ and others, although the association does not appear yet to have become a matter of general surgical knowledge. Further, H. Meige and Mme. Athanassio-Benisty⁴ have observed that the vasomotor, trophic, and secretory disturbances found in certain cases of nerve injury are not due directly to those nerve lesions, but are dependent on coincident arterial lesions, while Leriche⁵ has noted not only that so-called ischaemic paralysis may follow obliterating lesions of an artery, but has put forward the suggestion that the symptoms are the result not of the arterial wound, but of the concomitant injury to the sympathetic nerves which accompany the artery. He states, moreover, that if in such a case the whole of the obliterated segment of the artery be removed together with its nerve sheath the major part of the troubles disappear, the hand becomes warm, its colour changes, and the skin resumes its normal appearance, the fingers lose their stiffness in an appreciable measure, and, finally, the

pulse reappears at the wrist. Leriche has been able to demonstrate this in six cases, and in all the transformation was identical.

It is clear that if this pathology be established there is justification for a new title for paralysis of vascular origin, a title which shall include the two factors of ischaemia and sympathetic reflex disturbance.

Acknowledgments.—In conclusion, I should like to express my thanks to the medical officers, under whose care the cases quoted have been, for their friendly co-operation, to Colonel C. A. Ballance and Colonel Gordon Holmes for several helpful suggestions.

A CASE OF RAT-BITE FEVER TREATED SUCCESSFULLY BY INJECTIONS OF NOVARSENOBILLON.

BY

GEORGE C. LOW, M.A., M.D.,

TEMPORARY CAPTAIN I.M.S.,

AND

R. P. COCKIN, M.A., M.D.,

LONDON SCHOOL OF TROPICAL MEDICINE.

RAT-BITE FEVER—Sodoku of the Japanese—is a comparatively rare disease. It was recognized, quite a long time ago now, by Miyake and others in Japan as a definite entity. Cases have also been reported in England (Middleton, Horder, Cruickshank), in the United States of America, in France, and in Italy (Frugoni). As far as we are aware, our case is the first reported from East Africa or the tropics proper. The finding of the causative agent is of recent date. In 1915 Futaki and his fellow workers demonstrated the presence of long spirochaetes in the lymph glands of cases on the tenth to thirteenth day of the illness. Later they discovered in man, in the wound of the rat-bite, and in the blood of inoculated mice short, thick spirochaetes, and at first were unable to determine which of these two was the cause of the disease. Recent observations have, however, shown that the long and short forms are the same species, the long ones being old and found almost exclusively in human tissues, while the short ones are the young forms, and can be found in the blood of patients with the disease and in experimental mice (Kaneko and Okuda). Futaki's work has been confirmed by Kaneko and Okuda,¹ and it seems quite clear that rat-bite fever is another spirochaetal disease. According to the authors last named, the parasite can be found in the blood during the height of the disease.

Hata, in a paper published in 1912,² refers to eight cases of rat-bite fever treated by salvarsan. The results were striking; all symptoms quickly disappeared, and most of the cases were cured. Two relapsed, but in them the dose had only been small—namely, 0.3 and 0.4 gram. Since then other cases treated in a similar manner have been reported upon, and the recent discovery that the malady is a spirochaetal one fits in well with the undoubted efficacy of salvarsan and its derivatives in curing it.

The following is the history of a case we have treated recently:

Mr. H., aged 25, on January 31st, 1917, when in East Africa, was bitten by a rat on the back of the right forearm. He was sleeping in a mosquito net, and the rat attacked him through this, inflicting a severe bite. This healed up and was practically gone when, some seven days later, pain commenced at the site and the place swelled up. Fever then appeared, and with this a rash broke out on the body. Later the glands in the right axilla enlarged, and following this a general adenitis was noticed. On the twelfth day, after onset of symptoms, the bite, which had now broken down, was lanced and some pus escaped. About the twentieth day severe joint and bone pains came on, and the throat also became inflamed and very sore. The condition improved, but quickly relapsed, and between that time and the present (January 31st, 1918—namely, a year—patient can count nineteen relapses at varying intervals. There was a severe one in May, 1917. Complicating the real rat-bite symptoms, however, the patient had also suffered from malaria, and it is not certain which of the two infections was responsible for the different bouts of pyrexia. Malarial parasites were found in the blood in August, 1917, during an attack

Previous Illnesses.—Dysentery, much malaria (before the rat bite), never syphilis (he was very definite as to this), no history of tick fever, but here again the possibility of this disease is not excluded, as he has been in areas where it prevailed, and some of his friends had actually suffered from it; phlebotomus fever December, 1916.

First Examination.—The patient was seen first by one of us (G. C. L.) on September 25th, 1917, having been sent by Dr. A. M. Elliot for examination. He was then fairly well, and was only complaining of getting tired easily and of headaches. He looked a little sallow, was slightly anaemic, the spleen was palpable, and the glands in the right axilla and in the posterior triangles of the neck were definitely enlarged. The urine was normal, the blood showed no malarial parasites, but there was a definite large mononuclear increase. A diagnosis of rat-bite fever and malaria was made, and the patient was instructed to present himself immediately if any signs of a relapse appeared.

Second Examination.—On December 10th, 1917, he came again. On December 3rd he had an attack of fever in the middle of the day, for which he had to go to bed; the temperature rose to 104° F. This attack responded to aspirin and quinine, but he still complained of pain in the glands and in the back of the neck with more or less constant headache. The glands in the neck areas were big and very tender to palpation. They were also easily palpable in the other areas. Dusky coloured purplish-red eruption over trunk and neck and on the arm which had been bitten, its appearance being best described by the term blotchy. It was very typical of the eruption described in papers on this disease. Bones tender, no malarial parasites in the blood, no trypanosomes, no spirochaetes. Relapse of the rat-bite disease was diagnosed.

Treatment.—He could not begin treatment that day, but came to hospital on December 17th. The rash was then fading, but the glands were still tender and enlarged. We then decided that we should give him a course of novarsenobillon, and he had 0.4 gram that afternoon. He stood the injection quite well, and went home that evening. The second injection, 0.6 gram, was given on January 3rd, 1918. The eruption was gone, and the glands were very much smaller, being difficult to palpate. There had been no more fever, and the patient expressed himself as feeling much fitter. Bearing in mind the experience of Hata with relapses after one small dose, we thought it better to give a third and final injection on January 25th (0.9 gram). This produced chilliness and a slight rigor. A careful examination on that day did not reveal any more signs of the disease, the glands could not be felt, there was no trace of any eruption, no rise of temperature, and all the pain in the neck, together with the headache, had completely disappeared. On January 28th he expressed himself as feeling all right, with the exception of getting fairly easily tired and slight pain in his legs. In view of his malarial element, he was told to take 5 grains of quinine twice a day for the next three months.

As already stated, two or at the most three injections of salvarsan or its derivatives seem to cure rat-bite disease completely. The interest in this case lies in the double infection, which rendered the diagnosis more difficult. A Wassermann test was done before the treatment was begun. It was positive, as is usually the case in other spirochaetal diseases. Clinically, there never was any suspicion of syphilis, the history of the bite, the way the symptoms developed after it, the typical nature of the eruption, and the relapses all being characteristic of rat-bite disease.³ The same remarks apply to trypanosomiasis, which had to be considered in the differential diagnosis. In addition, no trypanosomes were found in the blood, and the eruption was not the same as is met with in that disease.

HOME DISINFECTION IN PULMONARY
TUBERCULOSIS.

By E. L. DOVE, M.B.,

RESEARCH WORKER IN THE HYGIENE DEPARTMENT OF
UNIVERSITY COLLEGE, LONDON.

The object of the following experiments was to indicate the simplest, cheapest, and most available means of countering the risks incurred when a sufferer from consumption shares living and sleeping rooms with others. It is doubtless the poor who run the greatest risk, more particularly because of their crowded circumstances and the greater difficulties they experience in adopting the necessary precautions; to them efficient chemical disinfectants are prohibitive in cost, and when distributed gratuitously by the local sanitary authority they are generally employed in a manner which gives but little security.

In the selection of measures to meet their needs regard must be had to the fact that, mainly owing to the increasing use of gas stoves, there is often no open fire (for at least many months of the year) for burning sputum, infected dust, paper handkerchiefs, etc. Therefore the advice here offered is based on the use of hot water, and the aim has been to define how this agent may be simply and effectively employed.

Floors.—Pieces of board were scrubbed and thoroughly disinfected and dried. They were then smeared with a thin layer of sputum containing tubercle bacilli. This was covered and allowed to dry, and on the following day one piece was scrubbed with hot water (as hot as could be borne) and yellow soap in the proportion usually employed in washing floors. This piece was then covered and allowed to dry, after which washings and scrapings of the infected surface into sterilized water were inoculated into guinea-pigs. Two out of three experiments gave negative results, the non-scrubbed board giving positive results in each case. The conditions of this experiment were those of very gross contamination, far in excess of what would occur in actual practice; and so it may be assumed that the process of good scrubbing with hot water and yellow soap will suffice in actual practice.

Experiments were made to ascertain whether soap in the proportion usually employed for scrubbing floors has any disinfectant value, since soap itself is practically sterile. The test organism employed was *Staphylococcus epidermidis* Welch, and the soapy water used was at a temperature (140° F.) well below the thermal death point of the organism. The results indicated that the soap had only a very slight effect, and that its only material value is the aid it renders in the collection and removal of dirt (with associated organisms) from infected surfaces.

Handkerchiefs, Pillow-slips, etc.—The ordinary staphylococcus of the skin (*S. epidermidis* Welch) obtained by rubbing a little broth on the skin of the hands and distributing a loopful of this over agar slopes was employed as a preliminary test organism. A pure culture was obtained on agar slopes, and it was found that the growths were killed by exposure for twenty minutes to a temperature of 75° C. in the form of moist heat; whereas the tubercle bacillus is destroyed at 70° C. in the same time. This staphylococcus is a more convenient germ to employ in preliminary experiments than the tubercle bacillus, the thermal death point of both organisms being about the same and the former germ being easy to cultivate.

Tuberculous sputum was sterilized by steaming for twenty minutes, and inoculated with growths of the staphylococcus. Sterilized strips of linen were soaked in this, then placed in cold sterilized water and gradually brought to the boiling point. Directly the water boiled the strips were removed and cultures made from the drops of fluid pressed out of them. In four sets of experiments there were no growths, while the control slips in every case furnished growths.

Boiling water was removed from the gas, and similarly inoculated strips of linen were immediately immersed and left for half an hour in the very hot water; they were then removed and efforts made to cultivate the germ. Again in four cases there were no growths on the strips so exposed, while all the control strips immersed in warm water furnished growths.

One pint of tap water was boiled and at once poured into a cold sterilized quart basin. Four strips of sterilized linen soaked in sterilized sputum which had subsequently been inoculated with the staphylococcus were immersed in the water and left there for fifteen minutes. The strips were then removed, and in no case was it possible to obtain growth from the water pressed out of the linen strip. The temperature to which the slips were exposed was at the commencement 90° to 92.5° C., and at the end 63° to 67° C. Control slips placed in warm water (50° to 60° C.) gave positive results.

Similar experiments were made with the basin filled with sterilized handkerchiefs and inoculated strips placed between them, the aim being to deal with as many handkerchiefs as practicable, provided they were just covered by a layer of water. After fifteen minutes the slips were removed and agar slopes inoculated with the water pressed from them. Controls in warm water gave positive results; but seven out of eight were negative from the slips exposed to a commencing temperature of 86° to 88° C., and an end temperature of 62° to 65° C.

For confirmatory purposes the last experiment was repeated with sputum considerably infected with tubercle bacilli. After twenty minutes the strips were removed and the material from them filtered and inoculated into guinea-pigs. In the control strips only warm water was employed. Two months after inoculation the three control guinea-pigs had enlarged caseating glands on the side of inoculation; both by *post mortem* and microscopic examination the infection was shown to be due to the tubercle bacillus. The nine guinea-pigs which had been inoculated from the strips exposed to nearly boiling water were healthy, except one, which had an enlarged femoral gland on the side of inoculation.

I desire to acknowledge my indebtedness to Professor H. R. Kenwood for valuable advice and assistance in connexion with the foregoing experimental work and the statement in which I have embodied it.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

ULCERATIVE GINGIVITIS: VINCENT'S ANGINA.

During the period of the war attention has been attracted to an ulcerative condition of the gum margins which is associated with the organisms described by Vincent. There would seem to be an idea on the part of certain writers that this is a disease discovered during the present war. Such is not the case. The clinical condition has been well recognized by dental surgeons for the last twenty years, cases constantly occurring in the clinics of the various dental hospitals. In John Hunter's famous work on the teeth there is an excellent description of this condition in the section on "Scurvy of the gums."

Amongst recent writers the credit of drawing attention to the subject should, I think, be given to J. S. Marshall of Chicago, who described the condition in the following words:

The clinical characteristics are the formation of ulcers at some point of injury, which at first appear in nowise different from the ordinary form of a localized ulcerative stomatitis, but which, after the lapse of twenty-four to forty-eight hours, begin to spread rapidly along the margins of the gingivae in all directions, involving both jaws, and sometimes extending to the hard palate and the floor of the mouth. The margins of the gums assume a general ulcerative condition, accompanied by swelling, redness, and considerable congestion of the parts, which bleed easily. Later they become covered with a dirty white or yellowish-white pellicle or membrane—somewhat resembling the thrush film—which sloughs off after a day or two, destroying the festoons and leaving a ragged surface. The denuded surface is very red and covered with coarse granulations, which bleed upon the slightest provocation. The gums are loosened from the necks of the teeth and the borders of the alveolar processes are exposed. Pus mixed with blood exudes from the inflamed tissue about the necks of the teeth. The breath and excretions are very fetid and salivation is profuse. In these respects the symptoms resemble mercurial ptyalism. The ulcerated surfaces are exceedingly sensitive and motions of the tongue and lips on this account are very painful. Food is taken with difficulty. Accompanying the local manifestations there is a general febrile condition, temperature ranging from 100° to 101° F., thirst, loss of appetite and general malaise, sleeplessness, and irritability of temper.

On the appearance of Vincent's publication it was apparent that there was a close similarity between the throat condition he described and that of the gums, and bacteriological examination showed that the latter condition was associated with the so-called Vincent's organism.

During the present war the condition has become widespread, and we have yet to find the real cause. One writer has suggested that it is to be found in the constant inhalation of putrescent matter.

The disease is seldom found in a clean mouth; by a clean mouth I mean one where the gingivae are normal. The ulceration usually starts around badly fitting crowns, in the deep pocket posterior to the lower third molar, and in mouth breathers around the necks of the lower incisors, but it may begin in any position where there is periodontal disease—in other words, in pre-existing "stagnation areas." These areas usually harbour organisms of the staphylococcal group, but in the case of Vincent's angina they have become infected with the organisms of that disease, which, as we know, are exceedingly toxic in character.

Treatment should be directed towards the irrigation of the pockets and the local application of drugs considered to have a specific action on the organism. Arsenical preparations have been advocated, but I have not found that they possess any advantage over iodine. Areas that cannot be easily irrigated should be eradicated, and it is most important that any mouth breathing should be corrected; as long as this is present the condition is extremely difficult to combat.

My principal object in writing this note is not so much to draw attention to the pathology of the condition, but to record the fact that we are dealing with a condition which was well known and recognized by dental surgeons long previous to the present war.

Honorary Consulting Dental Surgeon, Croydon War Hospital, and The Queen's Hospital, Sidcup.

Reports of Societies.

EYE-STRAIN IN GENERAL PRACTICE.

At a meeting of the Medical Society of London held on February 4th, with Dr. JAMES STOWERS in the chair, Major WALTER BROADBENT, R.A.M.C.(T.), read a paper on interlobar empyema and other surgical complications of the thorax, which was discussed by Dr. DE HAVILLAND HALL and Mr. HUGH LEE.

Dr. H. A. DES VUUX read a paper on the symptoms of eye-strain as met with in general practice. He said that the symptoms were hardly ever attributed to the eye as a possible cause, the patient declaring that the eyesight was perfect and the oculist usually saying that the defect was so slight as to be negligible. The following syndrome was produced by eye strain (including migraine: Fears and panics; depression of spirits and vitality; fits or attacks (including fainting); giddiness, dizziness, and vertigo; fatigue; indigestion; paralysis (functional); disorders of sleep; train vomiting. The paper was based on an analysis of 100 cases, consisting of 35 males and 65 females. In women the symptoms tended to be intensely aggravated at or about the catamenia. The age limit was very wide, but most of the patients could trace back symptoms to early youth or childhood. If surrounding conditions were favourable to their production the symptoms would first show themselves in a minor degree in childhood and become quite manifest about 15 to 25. The greatest success in treatment was attained at this age. The general health showed no alteration which would account for the symptoms: many complained of indigestion, without signs or symptoms of dyspepsia or any indication of disease or disturbance of the liver. Some patients suffered from colitis, but in most the eye-strain symptoms preceded this disease. Heart disease was conspicuous by its absence.

Analysis of Symptoms.

Headache or migraine was present in 60 to 70 per cent. of the patients. In some it constituted the chief if not the only sign; in others it was trifling or slight. The commonest seat of the pain was the frontal region, sometimes beginning on one side and passing to the other, sometimes beginning on both sides. Often it was definitely in the eyes, "through the eyeballs," "at the back of the eyes," with some tenderness of the eyeballs. The pain, however, might be vertical, occipital or temporal, but never parietal alone.

Depression of spirits was noted in 30 per cent., appearing generally to be due either to the frequent attacks and the dread of their recurrence, or caused by inability to take an active part in life, or by having to give up an occupation which was congenial or the only source of income. In some cases depression was the only marked symptom.

Fatigue was mentioned in about 40 per cent., produced apparently by the constant bodily suffering. Many had been typical neurasthenics and had been treated as such. As with migraine, it often began in the morning.

Fears and panics were often mentioned. Fears took the ordinary forms of unreasoning dread of what was going to happen, or some approaching catastrophe, or of a pending illness. The panics not unseldom took the form of claustrophobia.

Indigestion was frequently complained of, and was a marked symptom in 30 per cent. In most it was quite atypical; a want of appetite, distaste for food, and fullness or a little flatulence. The abdomen frequently felt normal, but in some cases there was undoubtedly definite and severe indigestion, with flatulent distension. Constipation was often marked, and in practically all the cases had always previously been assigned as the cause of the trouble. Disorders of sleep were very common. Insomnia was much complained of in twelve cases, but most patients mentioned some discomforts about sleep; it was often heavy, sometimes very restless. Whether the sleep was absent, intermitting, restless, or accompanied by dreams and nightmare, waking up unrefreshed was the ordinary result. Dropping to sleep during the day was frequently mentioned.

Giddiness or vertigo was present in one-fourth to one-third of the cases, of a similar type to that produced by other causes.

Attacks were complained of by many patients. Certain of these were undoubtedly true fainting or syncopal seizures. The fainting so common in crowded hot rooms, concerts, etc., was probably of ocular origin. Some of these seizures conformed in every respect to *petit mal*, and attacks of complete unconsciousness might occur. There might be some close relationship between eyestrain and epilepsy.

Among other symptoms noticed were an inability to concentrate; a feeling of unreality sometimes almost of dual personality; muscular twitching of the face, arms or legs, or

body generally; and irritability of temper. Train vomiting was prominently mentioned by five of the patients.

Transient paralysis was sometimes met with, mostly in those in whom migraine was prominent.

All patients immediately recognized that the symptoms were produced or intensified by railway travelling, sight-seeing, theatres, crowds, railway stations, big shops, shopping, race meetings, motoring, sometimes games of ball, and, less frequently, by hard and prolonged reading. They nearly all preferred to walk in side streets to main streets, and in the parks instead of the streets. They complained of "smoky rooms," "hot rooms," and "stiffness," but might live in a stuffy, hot, ill-ventilated house, and remain free from attack. It was a disease of town dwellers and brain users; as frequent in the quick, intelligent society gossip as in the studious. As time went on these things caused so much suffering that the patient tended to avoid them, and might drift into a life of a recluse.

With regard to the condition of the eyes, the orbits in a few cases were not horizontal, but set at an angle to one another. A more constant sign was twitching of the lower lid, very marked in some cases. Sometimes the eyelids were squeezed towards one another.

With regard to treatment, the patient must be sent to an oculist. Out of the 100 cases, 77 were reported on by an oculist; and of these 54 (or 70 per cent.) were hypermetropic and 14 (or 18 per cent.) were myopic. Both conditions were almost always combined with astigmatism. Nine cases had mixed or varied conditions. It was the slight degrees of error of accommodation which did harm. With extreme degrees the patient soon found out that he could not see without glasses; with slight degrees he could see perfectly well, but it was a strain to see, a strain not felt or recognized, but which produced results after a time. The human eye was made for man in the roving and agricultural life, and was not adapted for the restless, unceasing movement at close quarters in a town, entailing constant and rapid changes of accommodation.

Mr. ERNEST CLARKE accentuated the point that those with "perfect vision" were the most difficult to deal with. Oculists were much to blame, as they referred patients back to the physician after only a very superficial examination. Under ordinary circumstances small defects of vision were negligible, and the amount of nervous energy lost was a mere fraction of the whole; but with close, concentrated work this loss of energy became important, and the symptoms it caused could be cured by glasses. He had seen epileptoid attacks brought on by the nervous exhaustion caused by eye-strain. There was no functional nerve trouble which could not be caused by it. The importance of the subject was not yet recognized.

Dr. KENNETH SCOTT said that one proof of the fact that the symptoms were due to eye-strain was that they were cured by glasses, and that when the symptoms recurred it was found on re-examination that the condition of the eyes had changed. Patient and careful examination was most necessary, and glasses should be worn constantly. Out of 100 consecutive cases which he had seen 81 per cent. had astigmatism or astigmatic error of low degree (below 1 D.). The position of the astigmatism was important. When against the rule the symptoms were exaggerated and severe; when in one eye the astigmatism was against the rule, and in the other eye it was ordinary, the symptoms were less accentuated.

Colonel ERNEST KINGSOTE recalled a number of epileptics who suffered from error of vision, and emphasized the importance of the relation between these two affections.

ENTERITIC CONVALESCENTS.

At the meeting of the Liverpool Medical Institution on January 31st, Mr. W. THELWALL THOMAS, president, in the chair, Professor ERNEST E. GLYNN gave the substance of a special report on enteritis convalescents from the Thompson-Yates laboratory of the university. He said that there were now five types of bacteria recognized as pathogenic of enteritis: (1) Shiga's bacillus, (2) Flexner's bacillus, (3) typhoid bacillus, (4) paratyphoid A, and (5) paratyphoid B. A paratyphoid C had recently been described in Germany. Cases of dysentery had been detected among recruits who had never been out of England, and *histolytica* cysts had been discovered. Apart from the bacterial cause, it would

appear impossible to differentiate clinically typhoid B from other bacterial forms of typhoid. Paratyphoid (A and B) was more common than typhoid. The difference in temperature, the amount of distribution of the rash, the presence of haemorrhage from the various mucosae, were noted in paratyphoid cases as being more marked than in typhoid. In summing up the results of his observations, Professor Glynn expressed the opinion that in all cases of convalescent enteritis two examinations of the faeces should be made at an interval of one month. He regarded bacillary dysentery as endemic in England, especially in asylums. The importance of systematic bacteriological examination was insisted upon. There was still much confusion on the subject; a consolidation of the bacteriological findings of many observers, and their correlation with the clinical histories was greatly to be desired. The danger of carriers was emphasized, and any fresh outbreak should at once suggest the possibility of such a contingency.

RODENT ULCER.

IN a paper read recently before the Section of Medicine of the Royal Academy of Medicine in Ireland, Dr. WALLACE BEATTY discussed the different views regarding the origin and nature of rodent ulcer. He dwelt on the difficulties in explaining (1) the extremely benign course of rodent ulcer, if it is to be regarded as a carcinoma; (2) the difference in the character of the cells of the tumour, as contrasted with ordinary epithelioma, if its origin is from the surface epithelium. He considered the nervous theory of rodent ulcer attractive as it would explain these two difficulties. He compared the cells of the tumour to those found in soft naevi, which Unna had shown to originate from the epithelium of the surface. Dr. O'BRIEN said that no definite line of demarcation existed between non-ulcerated rodent ulcer and superficial epithelioma. The latter might remain dormant for ten years. Irritation seemed a causal factor in both. He had practised light therapeutics for twenty years, and in 1904 read a paper on the then position of radium therapy. In 1906 he showed cases of undoubted rodent ulcer cured by radium. Eight years later these cases were again shown, still well, and he hoped to have another opportunity soon of exhibiting them apparently cured. He considered radium bromide the best treatment, at any rate for superficial ulcers. Dr. HAYES thought that treatment should depend on the character of the growth. Carbon dioxide snow was excellent for very early cases, though x rays were also successful. He thought occasional doses should be given for several months after apparent cure was obtained. Cases in which cartilage and bone were involved presented most difficulty in selecting the most suitable treatment. No method was ideal for all cases.

SYPHILIS AMONG GYNAECOLOGICAL CASES.

At the meeting of the Ulster Medical Society on January 31st Dr. C. G. LOWRY read a paper on the incidence and manifestations of syphilis amongst gynaecological cases attending the extern department of the Ulster Hospital for Women and Children, 1912-17. The results are set out in the following tabular statement:

Total cases examined ...	1,729
Total number in whom syphilis, active or latent, was suspected ...	337
Unmistakably syphilitic ...	47
A strong suspicion of syphilis was entertained in 121 cases—	
Confirmed by Wassermann reaction in ...	87
Contradicted ...	34—121
A syphilitic element suspected in 169 cases—	
Confirmed by Wassermann reaction in ...	109
Contradicted ...	60—169
	337

In the 337 cases a reasonably sure diagnosis of syphilis was made in 243 cases either on clinical grounds alone or clinical grounds and history supported by a positive Wassermann reaction. Of the 94 cases which gave a negative Wassermann reaction, two at a later date gave a positive luetin reaction. Fifteen Wassermann reactions were

performed amongst the 47 undoubted syphilitics. All were positive. In 45 additional cases a tentative diagnosis of syphilitic influences was made, but from various reasons the blood could not be examined or results were thought unreliable or were contradictory. In all 305 patients were examined by the Wassermann test. The luetin test was applied to 15 patients. The paper gave rise to considerable discussion. Stress was laid upon the increase of venereal disease, the greatly increased number of cases of syphilis and gonorrhoea in the innocent, and of instances of the disease spreading in a family, and on the necessity of early energetic treatment with salvarsan and mercurial inunction.

Rebicus.

TUBERCULOSIS.

THE treatment of tuberculosis by means of the injection of "immunkörper," which was originally proposed by Carl Spengler, was primarily intended to meet the requirements of the case of low resistance and hence to be of service in advanced tuberculosis of the lungs. Many observers have used it, but not with uniform success. In a compact volume,¹ Dr. NIVEN ROBERTSON, of the Benenden Sanatorium, has set forth in concise form the chief points with respect to the therapeutic use of I.K. and an interesting account of the steps by which its properties were first studied and demonstrated by Spengler. His own experience of it does not appear to have impressed him with the same enthusiasm that has led others to use it almost exclusively. He relates several cases in detail the results of which would seem to have been little influenced by the special treatment, but so many other observers have recorded cases in which unexpected success has been achieved that he thinks the method ought to be more widely studied and tried, and the account of the whole subject as contained in his book will doubtless be found of great service by those who may undertake to make use of it. Spengler recognizes three varieties of bacillus: the original short bacillus demonstrated by Koch, a long bacillus recognized by himself, and the bacillus of bovine origin. Only the two former are usually detected in cases of pulmonary disease. The definition of *Immunkörper* is the acid blood of rabbits immunized against these two forms of bacillus and against pyogenic organisms, such as streptococci. The powers possessed by this blood are said to be lytic and antitoxic, as well as immunizing. Its method of preparation, properties, and practical employment in treatment are very fully described, and its specific action in experiments duly explained. While Spengler himself has gradually adopted it as a routine form of treatment, Dr. Robertson regards it as a useful adjunct to other means in properly selected cases. His account of the whole subject may be regarded as a complete summary of present knowledge with regard to I.K. therapy.

In his interesting *Three Clinical Studies in Tuberculous Predisposition*² Dr. W. C. RIVERS brings forward a mass of evidence to show that pulmonary tuberculosis is connected with three pathological conditions, namely, ichthyosis, squint, and nasal abnormalities such as adenoids, of which two at least do not at first sight appear to have any relation with it. These conclusions have been forced upon him by clinical observation, and he makes out a good case for their correctness. He believes that ichthyosis may entail a liability to consumption of the lungs; and that as ichthyosis is described by dermatologists as the most hereditary of skin diseases, the predisposition to tuberculosis that sometimes accompanies it may possibly sometimes be hereditary too. Squint Dr. Rivers holds to indicate in certain instances the presence of a predisposition to pulmonary tubercle, without itself forming an active constituent of a phthisical diathesis. In the essay on consumption and non-tuberculous nasal abnormality, which forms the bulk of the volume, the author states

that the nose is normal in only some 31 per cent. of consumptives, but in 63 per cent. of non-consumptives, and produces a great deal of evidence to show that nasal disease in general, by causing mouth breathing, predisposes to tuberculous infection of the lungs. The questions with which Dr. Rivers deals so fully and persuasively in this well-written volume are questions to be settled by the collection and analysis of statistics. It is certain that he will find many to agree with him in his endeavour to establish an endogenous factor—the soil—in the disease due to infection of the lungs with tubercle bacilli—the seed.

NOTES ON BOOKS.

THE fourth American edition of Professor KREHL's well known textbook, *The Basis of Symptoms*,³ follows rapidly on the third, which was reviewed in these columns in January, 1917. Since it does not appear that any very noticeable changes have occurred in the text, though the volume is bigger by fourteen pages than on the last occasion, there is no need to do more than endorse the opinions expressed in the last review. The American translation is well done and the work has been kept fairly up to date by insertions from Dr. Beifeld's pen.

Among the buyers of old pictures are a good many amateurs who like to trust their own judgement. They make mistakes, and it would not be in human nature did they not find solace in the mistakes of experts. Dr. RICKARD W. LLOYD has written a pleasant gossip book for amateurs. It is entitled *The Cult of Oil Paintings and the Romney Case*.⁴ Dr. Lloyd discusses the principles by which the buyer should be guided, but the story of the extraordinary conflict of expert evidence in the Romney case last summer and its dramatic ending, from which the book gains actuality, must leave the judicious amateur rather diffident of backing his own opinion by purchase. The book is illustrated by sixteen plates from old pictures, none of which, the author states, have been reproduced before.

The issue of the *Cambridge University Calendar* in 1913 contained nearly 1550 pages, forming a distinctly bloated volume. It was therefore decided to transfer in future the historical information hitherto contained in the annual calendar to a separate volume, appearing at much longer intervals under the title of the *Historical Register*.⁵ The first issue of this has now appeared. The new arrangement has given an opportunity of adding to the customary information. Thus the lists of holders of university offices, professorships, readerships, and lectureships, have been completed from the earliest recorded dates, with brief footnotes to the names of notable men. New sections have been added on university courts, ceremonies, customs, discipline, and other historical matters. Again, the Tripos lists of the old Calendar have been collated and corrected, and the footnotes revised to the end of 1915. The arrangement and printing of this interesting volume leave nothing to be desired. It is a mine of information, edited with scholarly care and precision.

A valuable summary of the literature dealing with *The Theory and Use of Indicators*⁶ has been made by Mr. PRIDEAUX. It is a book for the chemist and mathematician primarily, and makes no allowances for the weakness of physiologists or others whose acquaintance with chemistry and mathematics may chance to be incidental rather than profound. It approaches the use of indicators, or organic substances indicating the acidity or alkalinity of solutions by some characteristic colour, from the point of view of electrolytic equilibrium and molecular structure. It thus deals with problems of great interest to the chemical physiologist, the chemical geologist, workers in the fermentation industries, and technical chemists.

VENEREAL DISEASES.

PROPHYLACTIC AND ABORTIVE TREATMENT.

In the House of Commons, on January 22nd, Mr. Macpherson, Under Secretary of State for War, was asked by Mr. Peto:

Whether it was proposed to take any further steps to stop the spread of infection by venereal poisons among British troops; whether there was any Army Order which forbade or discouraged the necessary prophylactic medical measures, and whether it was proposed to issue an Army Order instructing army medical officers of superior rank to take the necessary action as a part of their regular medical duties. Mr. Macpherson, in reply, said that there was no Army Order authorizing the use of such preventives or forbidding them. The answer to the last part of the question was in the negative. In reply to a further question, Mr. Macpherson expressed the opinion that this was really a national question and not so much a military question.

On February 1st Mr. Peto asked a further question with regard to a War Office letter to General Officers Commanding, dated March 18th, 1916, which stated that the Army Council could not accept suggestions with regard to prevention which would imply the adoption of any system of prophylaxis which might be said to afford opportunities for unrestrained vice, whether this deterred army medical officers from taking steps to prevent the spread of venereal disease in the army, and whether the Army Council would now withdraw any restrictions which prevented effective measures being taken to avoid the waste of man power in the army from this cause. Mr. Macpherson declined to add anything to his answer of January 22nd, and in reply to a further question stated that he could not give accurate statistics of the number of men who passed through hospital suffering from venereal diseases in a year, and who were at any one time incapacitated from that cause. He added that it was not to be inferred that medical officers were prevented from taking every possible step to cure the diseases.

We have asked Mr. E. B. Turner, Chairman of Representative Meetings of the British Medical Association, and Representative of the Association on the National Council for Combating Venereal Diseases, for an expression of his views, and he has replied as follows:

I have been asked by the Editor to furnish him with a statement from my personal knowledge of the matters referred to by Mr. Macpherson with regard to prophylactic treatment of venereal disease, and the orders issued by the Army Council relating thereto.

I have given lectures on venereal disease ever since the commencement of the war, and I have been distinctly directed and ordered by the authorities not to introduce into the lectures any description of chemical personal prophylaxis, or in any way advocate its use. The lecturers are allowed to impress upon the men the importance of the earliest possible treatment if they find themselves infected, and also the wisdom of consulting their medical officers with regard to preventive or abortive early treatment if they have run the risk of infection but do not yet know whether they have been infected. Thus far the lecturers have been authorized to go by the Army Council.

With regard to the whole question of the issue of prophylactic outfits my personal opinion is that it might not be of much real use in diminishing the actual number of cases of venereal disease occurring in the army. In the first place no one can say that the methods afford absolutely certain and sure protection from the infection either of gonorrhoea or syphilis. Figures are always fallacious, but in the cases which have come under my personal knowledge the percentage of failure has been very high, and this can easily be understood when one considers the conditions under which infection generally takes place. The principal medical officer of one of the largest hospitals for venereal diseases in London lately traced the source of infection in the last 100 cases admitted into that institution; he found that of these 100 men only 28 had got the disease from professional prostitutes; the remaining 72 were the victims of what might be described as the amateur flapper. It therefore stands to reason that in many cases the necessary precautions to avoid infection would have to be taken not in the "ordered circumstance of a harlot's room" but in the open air, in barns, coppers, or commons, or behind a hedge, and therefore unless a man were extremely sober, very cold-blooded and skilful with his fingers, the chances are that he might fail to protect himself efficiently. It is pretty certain that an intoxicated or semi-intoxi-

cated man would almost infallibly fail in the minutiae of the protective process, and therefore become infected. If a man, as is very probable in some circumstances, incurs the risk of infection three or four times in a few hours, it is very improbable that before each performance he is likely again satisfactorily to protect himself.

It follows from all this that there will always be a certain percentage of cases infected even if prophylactic precautions are taken. If 100 men were exposed to the chances of infection unprotected, and 100 protected by prophylactic measures, in all probability the percentage of cases of infection would be a good deal larger in those unprotected. But if the doctrine of prophylaxis were widely preached and the efficacy of the methods insisted on, the chances are that a very much larger number of young men would run the risk of infection than is now the case.

I have no doubt myself that fear of contracting venereal disease of either sort is a very potent inducement to a large number of young men to keep straight, and I am sure that the impression that a perfectly sure method of avoiding infection could be used would lead a larger number of men to run the risk. If they know and thoroughly understand the fact that gonorrhoea is a very serious disease, and that syphilis in its latest stages spells ataxia and general paralysis of the insane, they are afraid of running the chance of contracting either.

It is a fact well known to all social workers that the standard of what I may call practical morality among young women of every class of society has gradually deteriorated since, some twenty years ago, the Malthusian propaganda began and the public display and advertisement of Malthusian appliances followed. The fear that a lapse from morality would mean an increase in the population was an extremely potent factor in ensuring the chastity of young girls.

I am certain that among young men the fear of infection with venereal disease acts in the same way, and I consider that on this matter I am probably better fitted to speak with authority than most men of my age and standing, because I was a competitor in first class athletic events until I was 38 years old, and before that time and ever since I have been in the closest touch with young men, athletes, in every class of the community, serving on committees and acting as president of athletic, cycling, and football clubs and as a member of the governing bodies of sport. If the idea that illicit sexual intercourse could be indulged in with impunity became at all general, I am sure that the gross number of cases of venereal disease would be by no means diminished, though the actual percentage of cases of infection after exposure would probably be a great deal lower.

Where I have spoken on several occasions at varying intervals at a camp, dépôt, or training centre for soldiers, I have been informed by the commanding officers that, after putting before them the results of these diseases and exhorting them by everything that a young man particularly holds sacred—his honour, his patriotism, his chivalry, and his sportmanship—to keep straight, the first result of the lecture has been to induce a certain number of men to report sick who had previously been concealing disease; a second result was that, so long as the particular unit to which the lecture had been addressed remained, there was a diminution varying from 50 to 80 per cent. in the number of cases of venereal disease reported.

If prophylactic outfits are issued and prophylaxis taught in the army, it stands to reason that the practice must be extended to civilians. Workers in munition factories are nearly as important as soldiers in the fighting line, and among them there is a fairly extensive prevalence of the disease. Further, if these methods are taught and put before men, it follows that they must also be put before women, a prospect from which I am not ashamed to say I recoil with horror.

In giving this statement I have put on one side every question of religion, morality, or aesthetics, and have confined myself simply to what as a physician and man of the world I consider likely to happen.

E. B. TURNER, F.R.C.S.

British Medical Journal.

SATURDAY, FEBRUARY 16TH, 1918.

ARMY MEDICAL RECORDS.

LET us begin by saying that we regard statistics with a reverence which might win the approval of Professor Karl Pearson and the keeping of records with a respect that would excite the admiring envy of a civil service official. But virtues carried to excess become vices, and the multiplication of elaborate notes made with a view to the assembly of facts and statistics warranting conclusions may easily end in such an unmanageable accumulation of documents as even the wide buildings of the British Museum shall not contain, nor all the calculating machines of all the statisticians reduce to even the semblance of order. To be set to make records, perhaps more than one copy, which the recorder feels certain can only cumber space that might more profitably be given to growing potatoes, is a drudgery to take the heart out of the most eager and industrious. Panel practitioners may judge from their own little piles the mountain the Insurance Commissioners and their clerks have already accumulated. The clerks are not to be blamed; it is the inevitable effect of the whole training of a civil service clerk to attach great importance to the document and little to the act recorded in the document; their nature is subdued to what it works in, like the dyer's hand. Only a few rare spirits escape, who, living down the suspicion of their colleagues, eventually become peers or undergo some less honorific form of extinction. But if the yoke of the Insurance Commissioners is heavy, the Army Medical Department put more to our yoke, and if the Commissioners chastise with whips the Army chastised with scorpions. Unless an officer commanding a hospital, as was no doubt the case in the majority of instances, put the clinical work first, even though the clerical work should suffer, medical officers might, under the old system, have to spend so much time in clerical work (note-taking, copying, etc.) that they saw little of their patients.

We would not be misunderstood. We fully recognize the importance of proper clinical records of soldiers who become patients of the Army Medical Service. They are of importance from at least three points of view. First, a sufficiently complete and accurate record of what has befallen a man and of the treatment he has received from each medical officer and in each medical unit through which he has passed, is important for the welfare of the individual. Owing to the conditions inseparable from medical work with an army in the field, the man must pass through a series of medical hands, and it is important that each succeeding medical officer should know not only the nature of the injury, which is often quite obvious, but should have also a summary note of the treatment applied at the various stages through which the man has passed before he reaches a home hospital. It is especially important that the information received with the man at the home hospital, where his final treatment is to be carried out and where possibly a primary or secondary operation must be undertaken, should be sufficiently detailed, in chronological order. This is necessary in order to

enable the surgeon under whose care he then comes to understand the history of the case and the nature of the attempts made during the various stages to put him in the way of recovery. It is also of importance that any system of records should work backwards; that is to say, medical officers with the armies abroad should be able to learn the after-histories of cases in order that they may be able to estimate the value of various methods of treatment adopted during the early stages of injury or disease.

In the second place such records will form the statistical basis of the medical history of the war, and during its progress they provide valuable data for the investigation of the prevalence of various types of disease and of the results of various forms of treatment, whether of disease or injury.

In the third place, the records will be of permanent national value in dealing with the vast number of claims for pensions and allowances which are arising now, and will arise in the future, and perhaps long after the war, among civilians who may attribute subsequent ill health to alleged previous disability produced by war services.

The case sheets, diet sheets, and the many other medical forms previously used in the army, though they may have been suitable to military hospitals in time of peace, were not well adapted to the new conditions created by the immense expansion of the armies, the general employment of medical officers drawn from civil life, and the establishment of very numerous auxiliary hospitals staffed by civilian practitioners unfamiliar with army forms and procedure. If the importance of each medical officer doing his share in the preparation of a complete record of each patient has not always and everywhere been fully appreciated, this may be set down, in part at least, to the cumbersome and vexatious clerical machinery which grew out of the old system, but which it is now decided shall give way to a simplified system of note-taking devised for the Army Medical Service by the statistical department of the Medical Research Committee.

The system devised by the official statisticians is founded on the new field medical card, issued on June 1st, 1917. This is intended to serve as a condensed diary of the patient's hospital career at the seat of war. The first entry on it is made by the Field Ambulance; it gives—in addition, of course, to the number, name, rank, and unit—the date of the wound or onset of illness, a note of the administration of antitetanic serum or morphine, and the diagnosis. The card is enclosed in a stout envelope, which is tied on to the man's tunic, and goes with him to the casualty clearing station. At that unit, as at the base hospital, any alteration or addition to the diagnosis is noted, and the inside of the folded card affords space for clinical notes. The envelope contains spaces for particulars of the ambulance train, convoy, and hospital ship by which the man is transferred, as well as for information regarding his special needs in transit. Temperature charts or additional notes may be sent in the envelope. If this field medical card is properly kept through the various stages, the patient reaches the home hospital with a brief clinical record of the early stages of his case. On his admission to an overseas base hospital another card—the index card—is issued. The necessary details of name, rank, unit, and so forth having been filled in by orderlies in the office, the card is taken to the ward, and comes under the charge of the medical officer, whose duty it is to fill in the diagnosis, with notes of any operation and its result, and of all complications in order of occurrence, and a brief summary of other important facts, authenticated

by his signature. When the patient reaches a home hospital from overseas, a similar card, printed in red, is made out for him; an index card of the same form, but printed in black, is used in home hospitals for men not belonging to an expeditionary force. The field medical card and the index cards eventually reach the Medical Research Committee, which arranges and files them for future reference.

The new system seems to have been carefully worked out in its application both to the expeditionary forces and to home hospitals. The three (or two) cards* taken together obviate, as we understand, the necessity of maintaining the old medical case sheet, which is no longer required, except for cases of special importance or interest. By their use the medical officer's note-taking for official purposes seems to be reduced to a minimum. For the reasons given above it is of the first importance that this minimum should in all cases be supplied. We are informed, however, that the statistical department of the Medical Research Committee views the disappearance of the case sheet with some apprehension, on the ground that in numerous instances it is the sole source of information on the previous history of the patient, information which may be of first importance in adjudicating on a pension claim. The Committee considers that ideally it would be desirable that the case sheet and the appropriate index card or cards should be maintained for every patient.

In addition to this uniform system, applicable to all patients, another more elaborate system has been set up to facilitate inquiries into special classes of cases, and there has, perhaps, been some confusion in the minds of some medical officers between the ordinary and the special system. Special note-taking schedules have been supplied by the Medical Research Committee to be used for grouping the records of special types of cases the treatment of which is being studied by chosen medical officers. These special subjects now make a rather long list, as they include wounds of joints and fractures of long bones; amputations; wounds of the head, chest, and abdomen; functional nervous disorders; injuries of the spine; disorders of the heart; nephritis; and gassed cases. Hospitals in France are supplied with post-cards asking home hospitals to transmit the schedules, and the information so conveyed to France has been used already in several important reports and articles upon selected groups of cases; some have been published, and others given to the conference of allied services in Paris. In particular directions treatment abroad has in this way either been confirmed as valuable or modified in the light of experience. Effort has been made so to frame the schedules as to give the minimum of trouble to the medical officer asked to fill them up. Special appeal is made to medical officers at home to give everywhere their cordial co-operation, but it is stated that a large percentage (nearly 70 per cent.) of the post-cards filled up and actually sent with patients from France are lost or ignored at the home hospitals.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

At a meeting of the Executive Committee of the Belgian Doctors' and Pharmacists' Relief Fund on February 7th it was decided to issue a circular letter to the medical and pharmaceutical professions appealing for contributions to maintain the fund. It was agreed to send to the Com-

*The cards, we are informed, are officially known as follows: A.F. W 3118, Field Medical Card, A.F. W 3162, used in British hospitals abroad. A.F. W 3243(A), printed in red; filled up in home hospital for men from B.E.F. A.F. W 3243, printed in black; for men admitted to home hospital not from B.E.F.

mission for Relief the sum of £400 to be forwarded to Belgium for the month of February; this compares with the sum of £800 sent monthly during last year. The Honorary Secretary, Dr. S. S. Sprigge, stated that since the last meeting the General Committee had been joined by Sir A. Garrod Thomas, M.D., M.P.; Lieut.-Colonel Adami, F.R.S., of the Canadian Army Medical Corps; Sir Thomas Barclay, Director of Southall Bros. and Barclay; and Mr. Harry J. Fisk, representing Parke, Davis, and Co. We may take this opportunity of saying once more that the need for renewed contributions to the fund is urgent. The previous appeal—that made in November, 1914—produced a sum of just under £21,000. By judicious investment during its gradual disbursement a further sum of £1,000 was earned in interest. At first the chief expenditure was made to relieve the necessities of the Belgian doctors and pharmacists, who, frequently accompanied by their families, had taken refuge in this country. They were helped to become self-supporting, and acting on the advice of Mr. Hoover, at that time director in Europe of the Commission for Relief in Belgium, and now Food Controller in the United States, it was resolved to send substantial sums monthly for disbursement in Belgium to doctors and pharmacists working in that country. These disbursements were made through a representative committee of Belgian doctors and pharmacists sitting in Brussels, and the Committee in this country is satisfied that the Committee in Belgium has acted throughout with prudence and discrimination. At the meeting of the General Committee of the Belgian Doctors' and Pharmacists' Relief Fund reported on February 2nd, p. 178, Dr. Des Vœux, the honorary treasurer, made a moving appeal on behalf of our Belgian colleagues. The act of the Belgian nation in withstanding the armed forces of Germany was, he said, a deed of courage beyond praise, and laid this country under a special debt of gratitude, because it gave Great Britain time to throw into Flanders a force which saved the Channel ports from occupation by the German legions. What the occupation of those ports would have meant to our empire could, he said, be deduced from the troubles which have followed the occupation of Antwerp, Ostend, and Zeebrugge. He showed from an analysis of the donations that subscriptions had been received from Great Britain, Ireland, Canada, Australia, South Africa, India, and some other parts of the British empire. The letter from Mr. Poland, who succeeded Mr. Hoover as director in Europe of the Commission for Relief in Belgium, published in the *BRITISH MEDICAL JOURNAL* of December 29th, 1917 (p. 864), afforded ample proof of the need for the continuance of the Fund. "If its supporters," Mr. Poland wrote, "knew how much actual suffering they had allayed, how much potential, moral, and physical suffering they had prevented, they would not cease to continue their support, many as are the claims now made upon them. This office is a gulf into which pours the stream of Belgian misery, and it would not be difficult to supply you with hundreds of testimonials as to the state of things there. . . . All the charities in Belgium are well administered. There is no leakage by the way. Only those who deserve it get relief, and never more than they need. . . . The knowledge that their associates in England have not forgotten them is an inspiration to the whole profession at a time when moral support is perhaps as much needed even as food." We may add that, owing to the self-sacrificing exertions of the treasurer, Dr. Des Vœux, and his secretary, Miss Brock, who has refused to receive any remuneration for her services, the Fund has been most economically administered, the total expenditure under this head for the first two years having amounted to only £50. Subscriptions may be sent to the Treasurer, Dr. H. A. Des Vœux, 14, Buckingham Gate, London, S.W.1. Cheques should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, and crossed "Lloyds Bank, Ltd."

ALCOHOL AND FOOD ECONOMY.

IN the fourth of the series of public lectures at University College, London (February 11th), Professor A. R. Cushny dealt with the value of alcohol as food. Strictly speaking, he said, alcohol must be regarded as a food in that the body could utilize it for heat and as a source of energy. In the completeness with which it was used up in the tissues it resembled sugar closely, and indeed sugar was a more complicated alcohol. Many substances, however, while carrying energy into the body, produced other effects, such as digestive or brain disturbance, which seriously detracted from their food value, and the drawback of alcohol was its effect upon the brain and upon other tissues ultimately. If alcohol could be obtained from such a source that it did not involve the destruction of other foods there might be an argument in favour of its use to some extent, but alcohol was obtained from cereals which could be used for food purposes. He had been unable to obtain the figures for beer production in 1917, and statements in Parliament on this point were conflicting. He had been compelled, therefore, to fall back upon the figures for 1916, when 26 million barrels of beer were brewed, and 955,000 tons of barley, 57,000 tons of grits, and 120,000 tons of sugar were used by the brewer. Only 60 per cent. of the barley, however, could have been made available for human consumption, but the grits could have been used entirely, and as for the sugar, although the Chancellor of the Exchequer had declared that it was not utilizable, many held a different opinion; in any case it had to be imported, and an equal amount of finer sugar might just as well have been imported in its place. The materials used for brewing, therefore, would have provided 750,000 tons of human food, and the remaining 40 per cent. of the barley would have furnished 382,000 tons of cattle food. It remained to determine the food value of the beer. This for the total barrelage for the year was placed at 2,200,000 million calories; that of the food available for human consumption destroyed in brewing was 2,651,000 million calories, making a loss of 17 per cent. In the case of the food for cattle, 283,000 tons of which were available after the brewing process, the loss in calorie value was similar—18 per cent. A still greater loss was apparent if the value of the grains in protein material were taken. The protein value of the barley and grits available as human food was 53,625 tons; that of the beer was only 4,250 tons, a loss of 90 per cent. The food available for cattle, on the other hand, represented a gain in protein after brewing, but in giving protein to animals only about one-sixth was returned. The lost protein and calorie value in the diversion of foodstuffs to the making of beer represented what was used up by the grain itself and the yeast plant. The embryo of the grain was caused to grow, which it did upon its own stock. At a certain point the growing grain was killed and put into the mash tub and infected with yeast, which grew rapidly, using up the original foodstuff. The amount of food taken up by the plant and by the yeast in growing would feed London for three weeks.

THE MEAT RATION.

THE Food Controller has now published the scheme for meat rationing for London and the Home Counties, which will come into force on February 25th. The meat card contains four coupons for each week; three of these may be used for uncooked butcher's meat, upon which each adult may spend 1s. 3d. a week. The fourth coupon may be used to purchase other meatstuffs—such as poultry, game (including venison), bacon, rabbits, sausages, cooked meats, and tinned meats—which are rationed by weights regarded in each case as the equivalent of 5 oz. of uncooked butcher's meat containing an average amount of bone. These equivalent weights have been published in a table. The general result is to make the weekly adult ration 1s. 3d. worth of butcher's meat—which

includes pork and suet—together with other meatstuffs equivalent to 5 oz. of butcher's meat; but there is nothing to prevent all four coupons being used for buying meats other than butcher's meat. Children under 10 will be entitled to half the above ration. Lard is not rationed, but is very scarce, as is also margarine; since butter also is very difficult to obtain it seems certain that the diet available will be deficient in fats. The scheme is admittedly experimental, and in particular the table of equivalent weights is subject to revision. Its effect on the amount of meat which will be available for a household is very difficult to estimate. A family consisting of a man, his wife, and two children over 10 years old would be entitled to spend 5s. a week on butcher's meat, and the Food Minister seems to assume that for this they will be able to buy 3½ lb., which is at the rate of 1s. 4d. a lb. We have seen no guarantee that meat will be available in this quantity or at this price per lb. The metropolitan district has been chosen as the *corpus vile* of the experiment, but what it is to suffer ten days hence Lancashire and the rest of England may have to experience next month.

SIR RICHARD CROFT, BT.

IN his interesting account of Sir Richard Croft, who shot himself on February 13th, 1818, as a result of depression consequent on the death in childbirth of his patient Princess Charlotte of Wales and the stillbirth of her male child, the anticipated heir to the throne of George IV, on November 5th–6th, 1817, Dr. S. D. Clippingdale¹ not only gives more detailed information about this student of St. Bartholomew's Hospital than is contained in the *Dictionary of National Biography* but throws a more favourable light on this unfortunate obstetrician than that in which he is usually shown. Sir Richard Croft did not take any diploma, but as this was not obligatory in his day, he was not then quite such an irregular practitioner as would be the case now. His fashionable practice no doubt owed much to his marriage to the elder twin daughter of Thomas Denman, the leading accoucheur and father of the future Lord Chief Justice, but he was able to take advantage of his opportunities, and in virtue of his position was selected, with Dr. John Sims and his brother-in-law, Matthew Baillie, to look after the Princess. This turned out to be a difficult and anxious task, and a path in the grounds of Claremont Palace is still shown where Sir Richard paced in an agony of doubt as to what should be done for the best, thus showing how libellous and cruel was the accusation of neglect made against this sensitive gentleman. The tragic death of the Princess raised a public outcry, to which Jesse Foot, the malicious biographer of Hunter, possibly stimulated by Matthew Baillie's post of responsibility, contributed two letters on the necessity for a public inquiry, and stated on the authority of the nurse that when the child was born the doctors were all asleep. The king ordered a necropsy, with the result that Sir Everard Home and Sir David Dundas reported that everything had been done for the best. But in spite of every consideration by the royal family and his many patients the tragic death of the Princess weighed heavily on Croft, and after an exhausting journey he put an end to himself, "Love's Labour's Lost" being beside him, open on the page containing the words "God save you; where is the Princess?"

MISSION OF AMERICAN SPECIALISTS.

OUR American friends when they entered the war began at once to make very elaborate preparations for their campaign. Among these preparations were inquiries directed to obtaining first hand information as to the experience of their European allies. As an instance of the care taken to examine all problems from every point of view may be mentioned the mission sent to Europe

¹ St. Bartholomew's Hospital Journal, London, 1918, xxv, 35–37.

some months ago by the American Surgeon-General, General Gorgas, to study certain special subjects. The mission consisted of Colonel T. C. Lyster of the United States Army Medical Corps, Major Harris P. Mosher of Boston, a leading laryngologist with a world-wide reputation, Major George E. de Schweinitz, the well-known ophthalmic surgeon of Philadelphia, and Major Isaac H. Jones, the noted otologist of the same city. Their mission was to observe and report on certain special military problems, particularly as regards the surgery of the eye, ear, nose, throat, and brain, and plastic and oral surgery, and to give special attention to the medical problems of aviation. They have spent three months in Italy and France, where they visited the American and British formations, as well as the French. The mission passed through London recently on its way home, and by the courtesy of Sir StClair Thomson a number of medical men in London had the opportunity of meeting its members. Although its stay in London was short, as it is due back to report at head quarters in Washington, the mission had time, amongst other institutions, to study the installation for facial surgery at Sidcup, and the working of St. Dunstan's Hostel for Blinded Soldiers and Sailors. Its members were much interested in the re-education of the blind, and were good enough to say that the work being done at the Queen's Hospital at Sidcup is not excelled anywhere. There is a suggestion that some American surgeons may be sent there for study. In addition to the pavilion for British soldiers, the Queen's Hospital at Sidcup is now equipped with pavilions for Canadian, Australian, and New Zealand soldiers under surgeons belonging to those Dominions; the addition of an American pavilion would emphasize the happy combination of people speaking the same tongue and fighting for the same cause.

MEMORIALS TO TWO MEDICAL WOMEN.

STEPS have been taken to raise a memorial to the late Dr. Elizabeth Garrett Anderson from the women of England. It will be devoted to the endowment of beds in the New Hospital for Women, Euston Road, which she founded in 1866. A sum of over £9,000 has already been received, and a number of women's colleges and schools have undertaken to raise £7,000. The honorary treasurer of the fund is Lady Hall, who may be addressed at the hospital. A committee has been established in Edinburgh, with Mrs. Johnston, 10, Wester Coates Avenue, as honorary secretary, to found a memorial to commemorate the life and work of the late Dr. Elsie Inglis. It is proposed to enlarge the hospice in Edinburgh, which since she established it in 1899 has done good work as a nursing home for poor women, and to endow it for the instruction of women medical students. It is also proposed to establish in Serbia after the war a memorial hospital and training school for Serbian nurses and to maintain during the war the Elsie Inglis Hospital in France.

CENTRAL HEALTH ADMINISTRATION IN FRANCE.

Dr. MOURIER, who represents the Gard in the French Chamber of Deputies, has succeeded M. Godart as Under Secretary for Health in the Ministry of War. M. Godart held that office for two years and a half. His successor was a member of M. Painlevé's Cabinet, and, as a member of the Army Commission, was the author of an act giving autonomy to the French Army Medical Service. There was some expectation that M. Clemenceau, in fulfilment of the policy he has long advocated, would take this opportunity of establishing a ministry of hygiene and public health, and the name of M. Augagneur, a member of the faculty of medicine of Lyons, at one time minister for the navy, was mentioned in connexion with it. The arguments in favour of such a course were similar to those which have been used for the establishment of a ministry of health in this country, the chief

being the multiplication of medical departments in various ministries—the ministries of the interior, of education, of labour, and of agriculture. The advocates of the change, driving the matter to its logical conclusion, seem to have desired that the army medical service, and that of the navy also, should be placed under the direction of the proposed ministry of hygiene. It was, however, admitted that this department alone would be sufficient to engage the attention of an independent ministry. It is probably largely for this reason that the simple course of merely replacing M. Godart has been followed, but it is interesting to note that the question of establishing a ministry of health in France has been raised at the very time when it is engaging attention in this country, and for similar reasons.

THE ARMY MEDICAL SERVICE TO-DAY.

IN an article on "The Army Medical Service To-day," published in the *JOURNAL* of February 2nd, p. 154, it was said that the continued enforcement of old army regulations requiring medical officers to prepare documents in triplicate in their own handwriting had aroused criticism. We are informed that the requirement as to autograph reports is not made in compliance with army regulations. This notification will, we have no doubt, be a relief to many medical officers.

Medical Notes in Parliament.

The New Session.

THE new session of Parliament was opened on Tuesday by a speech from the Throne, wherein His Majesty concentrated attention upon the war. The phrase attracting most notice was that in which the Sovereign spoke of the struggle as having reached "a critical stage which demands more than ever our united energies and resources." The interest in the debate centred mainly round Mr. Asquith's inquiries as to the Versailles Council and Mr. Lloyd George's reply.

The Army Medical Service.—After the storm thus raised had subsided, Sir W. Watson Cheyne said that various causes were at work antagonistic to the interests of the country; there was too much yielding to expediency, undue delay in making decisions and in taking action on them; parochial instead of wide views were allowed to prevail; underhand intrigue was not put down with a firm hand; and incompetence was condoned, and in some cases seemingly rewarded. While admitting that Government departments were overworked, he expressed the opinion that there must be something wrong when matters of importance which could be settled in a short time were kept under consideration for weeks and months. He referred to the delay in the publication of the report of the Committee which had made inquiry with regard to the medical service in France. He had been informed that the matter was under the consideration of the Army Council. It appeared that a copy had not been sent to France, and the consideration of the Army Council had now occupied two months. He thought the delay might be in part due to the fact that there was no medical member on the Army Council, and expressed the opinion that had the Director-General A.M.S. been a member of the Council when the medical arrangements were being devised there would have been no Mesopotamia scandal. He paid a warm tribute to the splendid work being done by medical officers in the army and by the sisters and nurses, and pointed out the great saving of life effected by the prevention of disease, especially typhoid fever.

Air Force Medical Service.—Sir W. Watson Cheyne went on to say that quite early in its work the Air Board had recognized the need of a medical service for the new force. A committee was appointed to advise, but action upon its report was delayed and it became known that some sort of intrigue had been going on with the view of preventing the establishment of a special service. Thereupon a second committee was appointed, which tried to keep the two older services in touch with the air service, and a compromise had been reached. The delay of many months such as had occurred was very serious; airmen were losing their lives for want of a proper medical service, and during the period of delay medical officers could not be trained to cope with their illnesses. Though he did not

think much of the compromise, he hoped that it would allow the air service to begin at once to train medical officers. If the compromise broke down, it would be possible to fall back on the original complete scheme.

The Reform Act.

THE Council of the British Medical Association, at its meeting last week, took steps to draw the attention of Divisions and Branches, both at home and abroad, to the importance of the representation of the medical profession on public bodies, especially at the present time, in view of the reconstruction proposals known to be in contemplation or likely to be proposed in various parts of the empire. As a preliminary to any further remarks upon the subject, it seems well to give a general account of the effect of the Reform Act placed on the Statute Book last week.

The Act will, it is estimated, add 8,000,000 voters to the electorate, of whom 6,000,000 will be women (5,000,000 married and 1,000,000 single). The total number of voters on the register will thus be brought up to 16,000,000, or, roughly, 1 in 3 of the population. When the Reform Act of 1867 was passed the proportion was 1 in 12. The enlargement in 1884, which brought in agricultural labourers, increased the proportion to 1 in 7.

Under the system which has now come to an end there were seven franchises carrying with them certain rights of plural voting. Under the new Act there are only three qualifications. The first, and numerically the most important, is the residential vote; the second, the business vote, and the third, the university vote. In future a man may not vote at a general election for more than one constituency for which he is registered by virtue of a residence qualification, or for more than one constituency for which he is registered by virtue of other qualifications of whatever kind. If he has other qualifications in addition to the residential, he must choose between his business qualification and his university right; he has also a right of preference to exercise a livery vote.

Leaving out of consideration for the moment men in the fighting forces, the qualification of men for voting is defined as 21 years of age and six months' residence or occupation of business premises. The university qualification is the attainment within the above age limit of a definite standard which in England and Wales is the taking of an ordinary degree. The election in a university will be the method of the proportional vote.

For parliamentary purposes a woman, married or unmarried, who for six months has been a householder or tenant of unfurnished rooms or the occupier of land or business premises of £5 annual value, has a vote if she has reached the age of 30 years. A woman also has a vote for local government purposes on the same qualification as a man—on attaining the age of 21. A married woman of not less than 30 years of age has a vote for parliamentary and local government elections where her husband is the tenant and he is entitled to vote as a local government elector. If a woman is 30 years of age and a partner in a business, she gets a vote if the annual value of the business premises occupied is sufficient to allow £5 for each partner. A woman may have a parliamentary vote for a university if she is 30 years of age, and either would be entitled to be so registered if she were a man, or has passed the requisite examinations and observed the conditions as to residence at the university. If a woman has one parliamentary vote in respect of her husband's qualification and another in connexion with her own business premises, she may not vote at a general election more than once, unless she has a university qualification, in which case she may exercise a second vote.

The period of qualification for the vote, both for men and women, has been reduced from twelve months to six. One period ends on January 15th and the other on July 15th; qualification is made easier by certain special provisions as to removals. The arrangements afford facilities for successive occupation, but puts difficulties in the way of the manufacture of the fagot voter.

The age qualification for naval and military voters has been fixed at 19 years. These war-service voters are to be registered for the constituencies for which they would have been qualified (with the concession as to age) but for their service. The provision applies also to merchant seamen, pilots, and fishermen, and persons engaged on Red Cross work, or other work of national importance abroad or afloat.

Two disqualifications have been made. Conscientious objectors to military service are disqualified during the war and for five years afterwards unless they satisfy the central tribunal that they have fulfilled certain conditions

such as employment in work of national importance. Aliens are cut out, the right of voting being limited to British subjects. The receipt of poor relief will not be a disqualification; residence in a workhouse does not give the qualification, but a limited stay in a workhouse owing to temporary exigencies does not constitute a barrier to voting qualifications.

The system of registration has been entirely changed. Two lists are to be prepared every year—in the spring and in the autumn. The cost of registration expenses will fall in half shares on the local rates and on the Treasury.

Nomination day is to be the same in all constituencies and all pollings are to take place on one day. Separate lists of the war-service voters are to be prepared. Ballot papers are to be sent to absent voters to be marked by them and returned with a declaration of identity, and to meet their case an Order in Council may be made to delay the counting of votes at any election for a period not exceeding eight days after the close of the poll.

The provisions of the Act, which have the effect of very largely reducing election expenses, involve a change which may prove to be of considerable importance to the medical profession. First, to lessen the danger of vexatious contests, each candidate is required to deposit £150, to be forfeited if the number of votes polled by him does not exceed one-eighth of the total number polled. The returning officer's expenses are to be paid by the Treasury. The maximum scale of election expenses has been fixed at 7d. for each elector in a county constituency and 5d. in a borough, but a candidate may, in addition, pay his agent a fee of £70 in a county division and £50 in a borough. It is impossible to make any close estimate of the cost of parliamentary elections in future, for under the redistribution scheme the size of constituencies still varies. The aim, however, was to take 70,000 inhabitants as a general unit of population for each constituency. The reduction in the cost as compared with the past will be great. Under the old system candidates had to bear a proportionate share of the official election expenses. The security that had to be deposited with a returning officer was in the case of a county or a district on a scale beginning at £150 where the registered electors did not exceed 1,000 and rising to £1,000 where the electorate approached a total of 30,000 voters. In the case of boroughs the deposit was £100 where the registered electors did not exceed 1,000 and £700 where the total approached 30,000. The candidate's personal expenses allowed for Great Britain were for a single candidate in a county division where the electorate did not exceed 2,000 voters, £650; where the electorate did not exceed 14,999 voters, £1,430, the intermediate figures being roughly according to a scale. For parliamentary boroughs the figures were for a single candidate where the electorate did not exceed 2,000 voters, £350; where the electorate did not exceed 14,999 voters, £740. The figures for joint candidates where the electorate did not exceed 2,000 voters was £525; where the electorate did not exceed 14,999 voters, £710. The Act contains a prohibition against outside associations flooding constituencies with oratory and literature. On the other hand, candidates are assisted because they are allowed free postal communications to the amount of not more than 2 oz. to each elector.

The qualifications and conditions as to local government elections remain very much the same as heretofore. There is a relaxation as to length of residence in respect of a candidate for local offices, but very few other alterations have been made. Some modifications were needed both as regards Scotland and Ireland. Scotland preferred to retain its existing local government franchise, which was rather wider than that for England and Wales, but as the women's vote was so closely concerned with local government, the latter had to be modified in Scotland for the purpose of creating women voters.

The redistribution scheme adds 37 members to the House of Commons provided that there is no diminution or withdrawal of Irish representation from Westminster in the interval. London boroughs gain three members, other boroughs 33, and the universities six; the counties lose five members. Of the 37, England receives 31, Wales 2, Scotland 2, and Ireland 2. The total membership of the House of Commons is thus brought up to 707.

THE late Dr. Edward Bard of Shrewsbury left estate of the gross value of £120,286.

OF the fifteen successful candidates at the recent examination for sanitary inspectors held by the Sanitary Inspectors' Examination Board thirteen received their instruction at the National Health Society and two at the Royal Sanitary Institute.

THE WAR.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Drowned.

LIEUTENANT K. H. BHAT, I.M.S.(T.C.).

Lieutenant Kalyanpur Harihar Bhat, I.M.S., was reported, in the casualty list published on February 6th, as "missing, believed drowned." He was educated at Madras University and at Charing Cross Hospital, took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1916, and joined the I.M.S. as a temporary lieutenant on March 11th, 1916.

LIEUTENANT C. C. W. MAYS, R.A.M.C.(T.C.).

Lieutenant Charles Cecil William Mays, R.A.M.C., was reported as "missing, believed drowned," in the casualty list published on February 9th. He was educated at Sheffield Medical School, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1900. After filling the posts of resident assistant medical officer of Woolwich Infirmary and of resident medical officer of Ecclesall Union Infirmary, Sheffield, he went into practice at Comynside, Sheffield. He had only recently joined the R.A.M.C. as a temporary lieutenant.

It has been announced that the transports *Aragon* and *Osmanieh* were torpedoed and sunk in the Mediterranean, the former on December 30th, with the loss of 610 lives, the latter on December 31st, with the loss of 199 lives. Eight nurses were reported as lost in the *Aragon*.

Died of Wounds.

CAPTAIN T. F. CRAIG, R.A.M.C.

Captain Thomas Forrest Craig, R.A.M.C., died of wounds received in action, on board a hospital ship, on February 2nd. He was the second son of the late Rev. A. M. Craig, of Kelso, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1910; afterwards he served as house-surgeon of the Whitehaven and West Cumberland Infirmary. He had taken a temporary commission in the R.A.M.C. a little over a year ago.

Died on Service.

Captain J. K. Palling, C.A.M.C.

Prisoner of War.

Captain H. J. Davidson, M.C., R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Bigger, John A. W., Second Lieutenant East Surrey Regiment, third son of Dr. W. G. Bigger of Streatham, reported missing May 8th, 1917, now presumed killed on that date, aged 24.

Cronyn, William Benn, Captain Army Veterinary Corps, third son of the late Dr. John Cronyn of Dublin, died of influenza and meningitis at Marseilles on February 1st. He was educated at Foyle College, Derry, took the M.R.C.V.S. in 1887, and joined the A.V.C. early in the war.

Fenner, Athelstan Lennox, Lieutenant-Commander R.N., only surviving son of Dr. Robert Fenner of Manchester Square, London, died on service, January 31st. He joined H.M.S. *Britannia* in 1903, and reached his present rank on January 30th, 1915. He went from Portsmouth to Hong Kong in command of submarine C 37, which, with C 36 and C 38, made what was then a record voyage. During the war he had served chiefly in submarines, and had received the Order of St. Stanislaus. His younger brother, Lieutenant Cyril Fenner, Scots Guards, was killed in the battle of the Somme in September, 1916.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SPECIAL Supplement to the *London Gazette*, issued on February 7th, contained a list of awards and promotions for services in connexion with the operations in Mesopotamia. The following medical officers are included in the list:

To be C.M.G.

Colonel (temporary Surgeon-General) A. P. Blenkinsop, C.B., A.M.S.

D.S.O.

Lieutenant-Colonel T. B. Kelly, I.M.S.

Majors (temporary Lieutenant-Colonels): R. M. Barron, I.M.S., F. P. Connor, I.M.S.

Majors (acting Lieutenant-Colonels): C. A. Gourlay, I.M.S., J. F. Whelan, R.A.M.C.
Major E. A. Roberts, I.M.S.

Military Cross.

Captains: H. Lal Batra, I.M.S., J. W. Dalglish, R.A.M.O. (S.R.), M. Das, I.M.S., P. K. Gilroy, I.M.S., J. W. Maclean, R.A.M.C.(S.R.).

Temporary Captains: R. C. Begg, R.A.M.C., R. D. Davy, R.A.M.C., R. H. Hodges, R.A.M.C., W. E. Hopkins, R.A.M.C., R. Y. Stones, R.A.M.C.

Lieutenant W. P. Hogg, I.M.S.

To be Brevet Lieutenant-Colonel.

Major (temporary Lieutenant-Colonel) W. H. Hamilton, D.S.O., I.M.S.

Major (acting Lieutenant-Colonel) J. C. H. Leicester, I.M.S.
Major W. H. Leonard, I.M.S.

To be Brevet Major.

Captains G. G. James, I.M.S., J. A. S. Phillips, I.M.S.

The Supplement also contains as amendments the following correct descriptions of officers whose rewards were published in the Supplement to the *London Gazette* dated January 1st, and in our issues of January 5th and 12th, 1918:

Awarded C.M.G.: Colonels Rupert M. Downes, A.A.M.C., Arthur T. White, A.A.M.C.

Awarded D.S.O.: Lieutenant-Colonel Charles E. Wassell, A.A.M.C., Major George W. Miller, R.A.M.C.

Awarded M.C.: Quartermaster and honorary Captain John H. Maunder, R.A.M.C.

COMMENDED FOR SERVICES.

A Supplement to the *London Gazette* issued on February 12th contains a list of officers whose names have been brought to the notice of the Secretary of State for War by the Army Council for very valuable services rendered in connexion with the war up to December 31st, 1917. The following medical officers are included in the list:

Surgeon-Generals: Sir David Bruce, C.B., F.R.S. (ret. pay, late A.M.S.), F. J. Jencken, A.M.S.

Colonel and honorary Surgeon-General M. W. Russell, C.B. (ret. pay, late A.M.S.).

Colonels: K. Cameron, C.A.M.C., W. Coates, C.B., V.D., R.A.M.C.(T.F.R.) (ret.), F. G. Finley, C.A.M.C., J. Griffiths, T.D., R.A.M.C., C. H. Melville, A.M.S., C. P. Oliver, K.H.P., T.D., A.M.S., G. S. Rennie, C.A.M.C., W. A. Scott, C.A.M.C., W. L. Watt, C.A.M.C.

Temporary Colonels: C. A. Ballance, C.B., M.V.O., A.M.S., A. E. Garrod, C.M.G., F.R.S., A.M.S., H. H. Tooth, C.M.G., A.M.S. (Lieut.-Colonel R.A.M.C.T.F.).

Temporary honorary Colonel Sir J. Collie, A.M.S.

Lieut.-Colonel (honorary Surgeon-Colonel, temporary Colonel) W. M. Roodcroft, V.D., R.A.M.C.

Lieut.-Colonels (temporary Colonels): D. M. McWhae, A.A.M.C., K. Smith, A.A.M.C.

Lieut.-Colonels: H. S. Anderson, R.A.M.C., J. Gordon, A.A.M.C., T. Mill, N.Z.M.C., A. de C. Scanlan, R.A.M.C., ret. pay (Reserve of Officers).

Honorary Lieut.-Colonel J. A. Murdoch, A.A.M.C.

Temporary Lieut.-Colonels: A. Balfour, C.M.G., R.A.M.O., J. C. G. Ledingham, R.A.M.C., G. B. Price, R.A.M.C., C. M. Wenyon, R.A.M.C.

Temporary honorary Lieut.-Colonels: G. S. Buchanan, R.A.M.C., H. R. Kenwood, R.A.M.C. (Major R.A.M.C.T.F.), J. Robertson, R.A.M.C.

Major and Brevet Lieut.-Colonel R. M. Carter, I.M.S.

Major (acting Lieut.-Colonel) J. A. Amyot, C.A.M.C.

Major T. W. Griffiths, R.A.M.C.

NOTES.

FAMILY HONOURS.

AMONG the officers who received decorations at the hands of the King at the investiture at Buckingham Palace on February 9th were three sons of the late Sir Thomas Crawford, K.C.B., Director-General of the Army Medical Service from 1882 to 1889. Two of them (Captains T. M. and H. G. Crawford), who received the M.C., both belong to the R.A.M.C.; a third son, Major J. D. Crawford, Indian Army, received this decoration and the D.S.O. also. Sir Thomas Crawford had six sons; of the other three, Lieut.-Colonel D. J. Crawford, R.A.M.C., received the D.S.O. some time ago, and Captain H. M. L. Crawford the M.C. Another brother, Engineer Commander W. R. Crawford, R.N., was mentioned in Jutland dispatches. It is probable that not many families can show such a record, but last week it was announced that the M.C. had been conferred on Temporary Captain E. A. T. Green, R.A.M.C., whose brother, Mr. R. A. Green, Second Lieutenant, Hampshire Regiment, received the same decoration about a year ago. Both are sons of Dr. James Green of Portsmouth, honorary secretary and treasurer of the

Southern Branch of the British Medical Association. We may recall also the distinctions conferred on the two sons of the Bishop of Liverpool, Captain N. G. Chavasse, R.A.M.C., who won the Victoria Cross and posthumously a clasp to the Cross, and his brother, Captain Francis B. Chavasse, R.A.M.C., who received the M.C.

FRENCH WOUNDED FROM THE AISNE.

In a communication made to the last meeting of the Académie de Médecine, Paris, M. Tuffier gave some statistics of the surgical results from the last French offensive on the Aisne. Although the action developed with great rapidity 80 per cent. of the wounded were quickly evacuated. Of the wounds 72 per cent. were produced by shells and 17 per cent. by bullets; 67 per cent. affected the limbs, 16 per cent. the head, and 4 per cent. the abdomen; in the remaining 13 per cent. the wounds were in various other parts of the body or multiple. The general mortality among all cases was 5.18 per cent., but among those wounded in the abdomen it was 61 per cent. The proportion of deaths from gangrene was 3 per 1,000 and from tetanus 0.5 per 1,000. In the majority of the wounded who died death was due to haemorrhage or shock. The system of evacuating and treating the wounded worked very well, so that forty-five days after the beginning of the operations only 1.43 per cent. were still retained in the advanced formations. M. Tuffier attributed this satisfactory result partly to the improved administration already mentioned, partly to the more intimate relations maintained between different surgical units, and partly to immediate disinfection and suture of wounds accompanied by the application of the Carrel-Dakin method.

Dr. Francis D. Boyd, C.M.G., temporary Lieut.-Colonel R.A.M.C., Physician to the Royal Infirmary, Edinburgh, and a member of the staff *à la suite* of the 2nd Scottish Territorial General Hospital, has gone to Egypt on his appointment as Consulting Physician to the British Army there.

England and Wales.

FIVE YEARS OF NATIONAL INSURANCE IN LONDON.

At a meeting of the London Insurance Committee on February 7th a quinquennial report was presented covering the work of the committee from the time it was constituted until the end of 1917. The report was mainly a history of the committee's activities which have been reported from time to time in these columns, but some interesting tables of statistics were added. The number of practitioners in agreement with the committee at the end of 1913 was 1,462, and at the end of 1917, 1,453. The total amount of the practitioners' fund in 1913 was £504,570; it fell each year until 1916, when it was £443,199; the number of units of credit rose in the same period from 1,138,569 to 1,465,342, and the amount paid for unit of credit fell from 8s. 10d. to 6s. The number of panel practitioners on military service at the end of 1917 was 252, and five practitioners had been killed in action or had died on active service. A large section of the report was occupied with an analysis of prescriptions, which was only carried to 1916. In that year the number of prescriptions submitted was 3,682,198 (the lowest on record), and the average value of each prescription was 6.37d. The mean number of insured persons as ascertained from the amounts credited for medical benefit in 1913 was 1,447,994, and fell each year until 1916, when it stood at 1,245,521. On the other hand, the mean number of index slips on the register has not shown the same tendency to fall, and in 1916 was 1,572,153. A central scheme is foreshadowed for clearing the index register and preventing a recurrence of such inflation. The number of questions or complaints raised by insured persons against practitioners during the five years was 446, of which 213 were substantiated. Questions raised by practitioners as to conduct during treatment numbered only 17, of which 9 were substantiated. The number of persons receiving sanatorium benefit varied within wide limits, from 801 in the middle of 1914 to 364 at the end of 1917. The waiting list also fluctuated greatly, from 40 or 50 at the end of 1915 to over 500 in the latter part of last year.

Scotland.

RATIONS IN GLASGOW.

ABOUT a year ago (February 24th, p. 266) we published a report by Miss Margaret J. W. Ferguson comparing the voluntary ration then in force with the ordinary diet of the poorer labouring classes in Glasgow. Miss Ferguson made a further report to the meeting of the Royal Society of Edinburgh on February 4th, giving the results of a further inquiry made in November, 1917, of eight among a number of families previously considered, five of them soldiers' families. They included three men, eight women, and forty-six children. The price of food had not risen since February. Some commodities were cheaper, and the average income had risen 20 per cent. The diet on the average of all families had become more adequate, but this rise was due chiefly to two families whose financial position was markedly better. Excluding them, the average was the same as in February. It appeared that the maximum consumption of bread, about 10 lb. a "man" a week, had been reached. On the present proportion of men, women, and children of the population this corresponded with 7½ lb. a person a week, or a little over 5½ lb. of flour. The cereals other than flour used corresponded approximately to ¾ lb. a person a week. Increased potatoes had not on the average been attended by decreased consumption of bread, and the amount of milk had not decreased. It appears that some 86 per cent. of the energy of food taken was derived from the articles now proposed to be rationed—cereals, meat fats, and sugar. In the food of the class investigated it seemed that unrationed foods could be relied upon to yield only some 14 per cent. of the necessary energy, and it was pointed out that this should be taken into account in framing the compulsory ration.

Ireland.

TREATMENT OF VENEREAL DISEASE.

At the last meeting of the Statistical Society of Ireland Professor McWeeney read a paper on venereal diseases and their treatment. The conspiracy of silence with regard to these diseases had, he said, been brought to an end by the appointment in 1913 of the Royal Commission, which reported in 1916. Its more important recommendations were now being put into execution in Ireland under the direction of the Local Government Board. The task of making the necessary arrangements had been imposed on the county councils. The general hospitals ought to be asked to deal with such cases, both as in-patients and out-patients; and, in view of the enormous loss of infant life, maternity hospitals should arrange for antenatal clinics in connexion with the scheme. Inasmuch as a large percentage of cases of blindness, deafness, mental deficiency, and other congenital defects owed their origin to these maladies, it was to be hoped the institutions specially devoted to such cases might see their way to participate in the advantages offered them under the scheme. The pathological laboratories of existing universities and schools of medicine were to be utilized for the diagnosis of specimens sent in by medical practitioners, and the necessary drugs for the treatment of syphilis would be supplied free. All expenses incurred by the local sanitary authority in carrying out the scheme would be defrayed as to 75 per cent. by the Exchequer, leaving only 25 per cent. to be paid by the local authority. In England and Wales schemes under the order were now in operation, covering areas comprising a population of over 20,000,000, and it was to be hoped that in Ireland the matter would also be actively taken in hand.

VACCINATION OBJECTORS.

The opposition to vaccination appears to be spreading. At recent proceedings at the Enniscorthy Petty Sessions it was stated that there were 8,000 vaccination defaulters in the union. In the six cases brought before them the magistrates imposed a fine of £1, with 10s. costs and 21s. expenses. Their solicitor said the defendants would go to gaol. In the Gorey Union, where the defaulters are said to number 1,482, the guardians have resolved to ignore the Local Government Board's letter.

Correspondence.

NEW DIET RESTRICTIONS.

SIR,—Since the food rationing scheme has been in force in the Chesterfield area I have been requested with increasing frequency to give permits for excess allowance of sugar, fats, meats, and milk. The cases vary from those which might seem to be desirable, such as extra meat for diabetics, to a general requisition for more sugar where no such allowance is at all called for. It is obvious that a very thankless burden is to be placed on the profession unless very strict limits are set to these demands. I am not aware if the profession will have power to grant such requests, but I feel sure it would be a great help if the council, who gave us a lead on the question of white flour, would also issue a memorandum on the limits that should be fixed to granting these further demands for various foodstuffs.—I am, etc.,

Chesterfield, Feb. 9th.

ARTHUR COURT.

*** We understand that representations have been made to the Food Controller with reference to the matter raised in the above letter, and that it is possible that a memorandum may be issued similar to that issued with regard to white bread by the War Bread Medical Subcommittee of the Ministry of Food, and published in the JOURNAL of October 20th, 1917, p. 524.

DIABETES, STARCH, AND SUGAR.

SIR,—Dr. R. T. Williamson draws attention to the part played by the consumption of sugar in the causation of diabetes mellitus. Are we to conclude that abundance of sugar is more likely to induce this disease than abundance of starch? Needless to say, this is a point of practical importance.—I am, etc.,

London, W., Feb. 12th.

HARRY CAMPBELL.

TONSILS AND ADENOIDS.

SIR,—From an extremely large experience as operator and observer Mr. Davis (BRITISH MEDICAL JOURNAL, January 26th, 1918) concludes that "the results of operations in the carefully selected and well-marked cases are excellent." He endorses the general preference of the surgical world for tonsillectomy over tonsillotomy, and he recommends the careful examination and selection of operation cases, and that an attempt should be made to ascertain and eliminate the cause of the condition under observation before the question of operation is finally settled.

The importance of his final recommendation has struck me very forcibly during the last two years in the examination of nearly 10,000 school children. The past records of school-child examination are more or less carefully preserved, but in the case of most children now examined above the "infant" age the records of one or more previous medical examinations are usually available for comparison, and I am surprised to find what a large percentage of children had tonsils enlarged in infancy of which no trace remains, in whom also there is no visible trace or verbal record of any operation having been performed. Hence a large proportion of enlarged tonsils disappear from natural causes—possibly from cessation of embryological function, as in the thymus gland, or from the proportionally smaller labours they are put to, as barriers to infective invasion, when the milk diet of infancy is replaced by other forms of food, and the fragile milk teeth by the more durable second dentition.

What the percentage of "vanished" tonsils may be to those now present matters little, but the fact that a great many do disappear naturally punctuates Mr. Davis's plea for a period of observation and elimination of likely causes before proceeding to operate. Personally, I believe dental examination and treatment, widely carried out, would greatly reduce the volume of tonsillectomies.—I am, etc.,

ARTHUR W. HARE, M.B., F.R.C.S.E.,

Gateshead, Jan. 28th.

Asst. Sch. Med. Offr., Gateshead.

A POSSIBLE RAILWAY DANGER.

SIR,—I should be glad to be allowed to draw attention to a recent railway accident the history of which brings into prominence a matter of interest to the medical profession. It happened in America and the man responsible for it was an engine-driver. Although under medical care, he was well enough to continue at work, but when driving a train he ran it past a series of danger signals and a number of lives were lost in the collision which ensued. It transpired that he had been treated with a medicine the ingredients of which included a soporific, and it was held that this was the direct cause of his failure to observe the signals.

There have been serious railway accidents in this country due to the default of drivers, and the reasons for experienced men failing in the essentials of their duty have remained obscure. They may or may not have been associated with the cause traced in the instance cited, but it will be permissible to suggest that patients among railwaymen concerned in the movement of trains, whether on the engine, in the guard's van, in the signal-box, or on the line of railway, should be warned of the danger involved in taking medicine of a soporific character in circumstances in which its effects might be experienced during a turn of duty.—I am, etc.,

February 4th.

A RAILWAYMAN.

THE PAY OF TERRITORIAL R.A.M.C. OFFICERS.

SIR,—I desire to draw attention to the position of junior officers of the Territorial R.A.M.C. compared with that of officers in other branches of the R.A.M.C.

There is considerable difference between the pay of the Territorial and the temporary commissioned officer. At home the Territorial officer draws £100 a year less than the temporary commissioned officer, and this without regard to seniority. A captain of the R.A.M.C. with seven years' service is entitled to an increase of pay, and it might have been assumed that the Territorial captain who had completed that period of service would have received that small addition to his pay. But no; shortly after the outbreak of war an instruction was issued stating that the seven years' service meant mobilized service. The Territorial officer is entitled to a certain war gratuity which, after a time, is much the same as that given to the temporary commissioned officer. The latter has his pay made up to £500 a year by the addition of a bonus of £60 paid annually, whereas the Territorial captain, whose pay amounts to £282 17s. 6d., has to wait until the end of the war for his war gratuity.

At the beginning of the war, when units were being rapidly formed, many officers were promoted to field rank in order to complete establishments, and this in many instances was done without reference to merit or seniority. Captains in field ambulances and on the staffs of hospitals became majors and lieutenant-colonels, while others who remained with the combatant units to which they had been attached in pre-war days were passed over to France and served in the trenches with them, but the possibility of promotion was denied to them. Thus to-day there are many senior officers in the R.A.M.C. Territorial Force who are still captains, while their contemporaries, and in some cases their juniors, hold much superior ranks.

If a Territorial officer is sent to India the position is infinitely worse. His slightly increased pay scarcely exceeds the sum of his pay and allowances at home, and is much less than in France. He receives no allowances except the trivial "exchange compensation allowance," and this is being reduced by half; he receives no free quarters and no rations, and he is never allowed to go home unless the condition of his health renders him unfit for further service.

The remedies are obvious and simple. So far as pay is concerned the rate should be the same for both Territorial and temporary commissioned officers; or, if the Territorials must be on the same footing as the regulars, they should have the benefit of the slight increase of pay after seven years' commissioned, not mobilized, service; and there ought to be an additional increase to compensate for the pension the regular is earning, and the war gratuity should be paid annually.

A seniority list of all the Territorial officers should be drawn up, as has been recently done in the case of the more

highly paid Royal Engineers, and, other things being equal, strict regard should be had to that list.

An officer might be given an option, when the exigencies of the service permit, of serving in India for a definite period, and while there he should be provided with free quarters and rations, or an adequate allowance in lieu thereof.

The attention of Parliament should be drawn to the gross injustice and the unfair treatment meted out to the officers who had the misfortune to belong to the Territorial R.A.M.C. before August 4th, 1914.—I am, etc.,

Edinburgh, Feb. 7th.

J. W. L. SPENCE.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on February 9th the following medical degrees were conferred:

M.D. - H. J. Gauvain, G. L. Keynes.

UNIVERSITY OF LONDON.

At a meeting of the Senate on January 23rd a committee was appointed to inquire into the question of the admission of Dominions' soldier and sailor scholars medically unfit for further service to the university as internal students.

Regulations were adopted, to be in force during the war, by which external students passing the first examination for medical degrees Part I in December may be admitted to the second examination in the following March.

Studentships.—Candidates for the Lindley Studentship and the University Studentship in physiology, value £100 and £50 respectively, to undertake research in physiology, must send their applications to the Academic Registrar, from whom full particulars can be obtained, by April 30th and May 31st respectively.

PARLIAMENTARY REPRESENTATION OF UNIVERSITIES.

UNDER the new Reform Act the representation of universities has been increased by 6. The number of members now allotted is: Oxford, 2; Cambridge, 2; London, 1; Wales, 1; Durham, Manchester, Liverpool, Leeds, Sheffield, Birmingham and Bristol, 2; Aberdeen, Edinburgh, St. Andrews and Glasgow (together), 3. The principle of proportional representation is introduced for universities represented by two or more members. The Irish University representation, like the other representation of Ireland, remains unaltered.

The Services.

THE AUXILIARY R.A.M.C. FUNDS.

Officers' Benevolent Branch.

WE have received a letter from Major A. C. Farquharson, R.A.M.C.(T.F.), a member of the Committee of the Auxiliary R.A.M.C. Funds, but as it is not quite self-explanatory we propose, with his sanction, to explain the situation to which he wishes to call attention.

In the first place it is to be remembered that there are two funds managed by the same committee—the one for the benefit of officers, the other for that of non-commissioned officers and men. The remarks we have to make refer only to the fund for officers (the Officers' Benevolent Branch), which is for the benefit of the Special Reserve, Territorials, and those holding temporary commissions in the R.A.M.C. The funds were established at a meeting, under the chairmanship of Sir Alfred Keogh, on June 26th, 1916. A scheme was submitted to this meeting, which has since been modified in certain respects, the most important being that the original limitation to orphans has been altered so as to allow assistance to be given to the children of officers totally disabled. The rule that orphans of officers who are non-subscribers to the fund shall have no claim on its benefits appears to be maintained and would, we assume, apply to the children of disabled officers.

An account of the work of the Officers' Branch Fund down to the end of 1917, furnished to us by the honorary secretary, was published in the JOURNAL of January 12th, p. 71. The first annual general meeting was held on October 26th, 1917, but we were unable to give a report of the proceedings at the time as reporters were not admitted. We learn that the accounts made up to September 30th, 1917, showed that a sum of a little over £4,000 had been received in subscriptions and donations, and that of

this sum £3,800 has been invested in new War Loan at 5 per cent. As already reported, the annual meeting approved grants amounting to £160 to the orphans of four officers with temporary commissions and two officers in the R.A.M.C.(Territorial). We find that at this meeting Major W. T. F. Davies, D.S.O., M.D., urged that an appeal should be made to the profession throughout the United Kingdom, a suggestion which we had ventured to put forward on June 24th, 1916, when the Fund was about to be formed. We gather that at the annual general meeting Major E. H. T. Nash (T.C.) also expressed the view that an appeal should be made to others not serving in the Auxiliary Branches of the Corps. In speaking on this point, Major Farquharson said that his own experience of an effort in this direction at Christmas, 1916, had not been encouraging; he had sent out a large number of letters but had only received £6 from civilian practitioners engaged in part-time duties in the Northern Command and not connected with hospitals. The note of his speech in the report of the first annual general meeting issued by the Funds has given the erroneous impression that this was the whole result of his appeal. The response from officers was good; he received in donations and subscriptions some hundreds of pounds, and the late secretary of the Fund acknowledged that if all the other Commands had done (at that time) half as well as the Northern Command the success of the Fund would have been assured. "The R.A.M.C. did splendidly, the civilian practitioners did not." Major Farquharson goes on to deprecate optimistic and fanciful estimates of the amount of donations that will be expected.

The sum received in donations down to September 30th, 1917, appears to have been £2,548, and we gather that nearly the whole of this has been in gifts from officers holding commissions in the Auxiliary Branches R.A.M.C. The number of subscribers in 1916 (six months) was 503; at the end of 1917 it had been increased to over 1,200.

EXCHANGES.

Medical Officer in charge of a cavalry unit in France desires exchange with medical officer serving in England.—Address, No. 593, BRITISH MEDICAL JOURNAL Office, No. 429, Strand, W.C.2.

Medical Officer in charge of a motor transport unit in France desires exchange with medical officer serving in England.—Address, No. 600, BRITISH MEDICAL JOURNAL Office, No. 429, Strand, W.C.2.

Obituary.

By the death of Dr. THOMAS LAFFAN, Cashel, co. Tipperary, which occurred in his 76th year, an able and many-sided personality has been lost to the profession in Ireland. A son of the late Mr. D. Laffan, solicitor, Dr. Laffan was a well known politician, philanthropist, and controversialist. He was formerly demonstrator in anatomy in the Catholic University, Dublin. Old students will recall the strenuous and successful fight he made for the conferring of degrees (*ad eundem*) on graduates of the old Catholic University by the Senate of the National University, he himself being one of the first recipients. He contributed many articles to the French and English medical press, and was the author of an essay on the grievances of Poor Law medical officers. He was a past president of the South-Eastern (Ireland) Branch of the British Medical Association, and for several years acted as its representative at the Annual Representative Meeting, where he frequently enlightened and amused, by his contributions to debate, his British colleagues. He was surgeon to the Cashel Infirmary, and enjoyed a lucrative practice. He was a member of the Cashel Urban Council. As a speaker and writer of independent thought on Irish National affairs he was also widely known.

WE regret to record the death, on February 7th, of Mr. W. H. JALLAND, of York, after a long illness. He was born at Nottingham, and received his medical education at Guy's Hospital, taking the diplomas of M.R.C.S. in 1870, L.R.C.P. in 1871, and F.R.C.S. Eng. in 1873. After holding the offices of house-surgeon and resident obstetric officer at Guy's Hospital, Mr. Jalland joined Mr. W. D. Husband, of York, who was a very active member of the British Medical Association. Mr. Jalland became a member of the Association, and retained his membership throughout the whole of his professional career. He was president of the Yorkshire

Branch in 1894, and vice-president of the Section of Surgery at the annual meeting at Sheffield in 1908. He was for over thirty-four years surgeon to the York County Hospital, and for some years a member of the house committee. On his retirement in 1914 from the office of surgeon the committee elected him consulting surgeon, and recorded its appreciation of the value of his professional work for the hospital, and the indefatigable energy he showed in assisting it financially, both by his own gifts and by his influence with others. He was surgeon to the 1st Volunteer Battalion West Yorkshire Regiment (York Rifles) for over seventeen years, and retired with the rank of surgeon-major. He was much interested in ambulance work, was president of the York centre and a Knight of Grace of the Order of St. John of Jerusalem. Since the war began he had given much time to the military hospital in Haxby Road, of which he was surgeon. Mr. Jalland was a J.P. for the North Riding of Yorkshire, and deputy lieutenant for the West Riding; he was sheriff of York in 1896. He is survived by his widow, a daughter, and a son; another son, a lieutenant in the East Yorkshire Regiment, was reported missing and subsequently presumed killed after the Suvla Bay landing.

SURGEON-GENERAL SIR ADAM SCOTT REID, K.C.B., Indian Medical Service (retired), died of pneumonia in a nursing home in London on February 2nd, aged 69. He was born on April 4th, 1848, educated at Edinburgh University, where he graduated M.B. and C.M. in 1869, and entered the I.M.S. as assistant surgeon on March 31st, 1872. He became surgeon on July 1st, 1873; surgeon-major on March 31st, 1884; surgeon-lieut.-colonel on March 31st, 1892; brigade-surgeon-lieut.-colonel on June 9th, 1897; full colonel on May 19th, 1899; and surgeon-general on June 16th, 1902; and retired on March 25th, 1907. He served in Afghanistan in 1879-80 (medal); in the Chin-Lushai campaign on the North-East Frontier of India in 1889-90, with the Burma column (medal and clasp); and in the North-West Frontier campaign of 1897-98, when he took part in the relief and defence of the Malakund, in the relief of Chakdara, and in the operations in Bajaur and in the Momund country, was mentioned in dispatches, and received the medal with two clasps. On his promotion to the administrative grade he was posted as administrative medical officer and sanitary commissioner of the Central Provinces, and during his tenure of that office initiated and presided over a conference on malaria at Nagpur in 1901. In February, 1902, he was appointed inspector-general of civil hospitals in the Punjab, and on June 16th, 1902, surgeon-general of the Punjab Command, holding that post till his retirement. Except for the three years May, 1899, to June, 1902, during which he held civil administrative appointments, his whole service was spent in military employ. He was granted a good service pension on December 2nd, 1901, was made a C.B. on June 26th, 1903, and promoted to K.C.B. on June 23rd, 1911.

THE death occurred at Catcliff, Bakewell, Derbyshire, on January 15th, of Dr. PHILIP SHELTON FENTEM. He was the son of the late Thomas Fentem, F.R.C.S.Eng., and was born at Eyam on November 8th, 1841. After being apprenticed to his father he proceeded to Edinburgh. He took the diploma of M.R.C.S.Eng. in 1863, and the degree of M.D.Edin. in 1865. He settled in Bakewell in 1865. He was the first M.O.H. for the Urban District of Baslow and for the Northern Division of the Bakewell Rural District, and afterwards was appointed M.O.H. for the whole district. He retired from the post of district medical officer and public vaccinator for Bakewell District in 1916, having held these offices for forty-seven years. He was actively interested in ambulance work, and was an honorary life member of the St. John Ambulance Association. He took an active share in local affairs as churchwarden, member of the Local Board, and one of the original Governors of Lady Manners School, Bakewell. Dr. Fentem belonged to the best type of general practitioner. His quiet courage enabled him to meet the difficulties of rural practice, but he was perhaps at his best as an obstetrician. Sir James Young Simpson advised him to remain in Edinburgh and specialize in that work, but the charm of a country life called him. He made a fine collection of old oak furniture,

and on that subject was an authority. Though of a retiring disposition, all knew that behind his reserve was a kind and generous heart, and many sought his advice in their troubles, not as a medical practitioner only, but as a true friend. He was for many years a member of the British Medical Association, which his father had joined soon after its inception. He married the daughter of Mr. Robert Mackay, of Fountain House, Loanhead. She died in 1909. He leaves one son, with whom he has been in partnership many years, and two daughters, to mourn his loss.

Medical News.

DR. E. RYAN, J.P. (Crumlin), has been elected a member of the Monmouthshire County Council.

DR. S. RIDEAL, public analyst for Chelsea, has been elected president of the Society of Public Analysts.

At a meeting of the medical profession in Guildford, held on December 29th, 1917, it was unanimously decided that it was necessary that the fees for medical attendance in Guildford and district must be raised.

A QUARTERLY meeting of the Medico-Psychological Association of Great Britain and Ireland will be held at the Maudsley Hospital, Denmark Hill, London, S.E., on Thursday next, at 2.30, when Lieut.-Colonel F. W. Mott, M.D., F.R.S., will read a paper on war psychoses and psychoneuroses, and demonstrate the microscopic changes in the brains of fatal cases of shell shock and gas poisoning. It is hoped also that Professor Marinesco of Bucharest will give a microscopic demonstration.

INFANTILE beriberi due to breast-feeding by mothers with the disease in a latent or declared form has been recognized in two forms: (a) the chronic aphonic lasting for several weeks, with a hoarse voice and a dilated and hypertrophied right heart, and (b) the acute pernicious cardialgic, lasting from several hours to two days, and characterized by intense and incessant crying. In addition, J. Albert (*Philippine Journ. Sc.*, 1917, vol. xii, p. 166) briefly describes the pseudo-meningitic form in infants of five to six months, or somewhat older than the ordinary cases. Ptosis giving the infants an idiotic expression is a prominent feature; drowsiness, retraction of the head, and upward rotation of the eyes also occur. The right side of the heart is shown by x rays to be enlarged. In two out of the three cases there was a history of previous aphonia, thus suggesting that the meningeal symptoms were due to a second attack of beriberi. The cases were rapidly cured by the extract of tiqui-tiqui, which is a specific for infantile beriberi.

THE report presented and adopted at the annual meeting of the Scottish Poor Law Medical Officers' Association early this month stated that it had not been necessary to warn any applicant against accepting an appointment because the information supplied by the secretary, Dr. W. L. Muir, 1, Seton Terrace, Glasgow, as to the area, population, difficulties of locomotion, etc., had been sufficient to deter applicants. The claim made upon the Highlands and Islands Medical Service Board was for a guarantee of a dwelling-house, rent and taxes free, expenses of a professional nature, and a free income of not less than £300 a year. It was thought that it would be well that the medical officers should formulate their grievances and appoint a deputation to interview the Board. The position created by the action of some parish councils in adding the whole of the old age pensioners to the list of medical officers was under consideration. A suggestion had been made that a capitation grant of nine shillings for medical attendance and medicine should be paid by the parish council for each old-age pension case.

THE current number of the *Nordiskt Medicinst Arkiv* (Bd. 50, Heft 3-4) presents a remarkable feature in the number of papers which are written in the English language. It has been a rare occurrence hitherto to note a single paper in English. Of eleven papers, nine now appear in English and two in German. The *Nordiskt Arkiv* has always maintained a high standard for the contributions it accepted, and this somewhat new departure will tend to make it more generally read and appreciated among the English-reading races, and more specially among the surgeons of the British empire and America. The current number contains articles upon the surgical treatment of the reflex dyspepsia associated with chronic constipation, the examination of gall stones by x rays, the prognosis of otogenic sinus phlebitis, septic lung diseases in connexion with clearing out of teeth, on sliding hernia,

appendicitis and the functions of the gall bladder. This delicate expression of cordiality in the Scandinavian countries towards the English language may, perhaps, be taken as the expression of sympathy and encouragement in our fight for what is right and true and free.

HERMANN KÜTTNER (*Muench. med. Woch.*, August 14th, 1917), consulting surgeon in the German navy, has drawn attention to the fact that the explosive action of projectiles in the body is not confined to the rifle bullet. This effect of the rifle bullet had, he says, in recent wars been the cause of numerous mistakes and false accusations, but omits to confess that the Germans floundered heavily into this pitfall early in the present war. Küttner recognized that fragments of shells and bombs may inflict a single wound of entry and numerous wounds of exit. He has seen a whole series of such cases, and he believes that they are not rare. He has seen not only single wounds of entry and multiple wounds of exit inflicted by shell fragments, but with the x rays has demonstrated the presence of many fragments of shell in the body, though there was only one wound of entry. He reproduces photographs of two metal boxes for holding a gas mask outfit which had been struck by fragments from aerial bomb. Both boxes show a single hole of entry, while on the opposite side there were many large and small holes of exit. An analysis of the splinters from the bombs revealed no intrinsic explosive qualities, only nickel molybdenic steel.

FROM several thousand examinations during the last three years J. A. Johnson (*Phillipine Journ. Sc.*, 1917, xii, Sect. B., 115) has been led by its varying morphological appearances to classify *B. leprae* into four groups: (1) The classical, common in comparatively recent macular and nodular lesions, and occasionally seen in old lesions becoming active again. (2) Fragmentary (degenerative) with (a) coarse, (b) fine granules; the granules are probably evidence of degeneration, as the fragmentary form is rare in active lesions and common in old inactive lesions, and in patients treated with chaulmoogra oil. (3) Solid form, (a) long, (b) short, is rare, and is found in the ulcer on the septum nasi, and at the margin of chronic ulcers. (4) Nocardial or streptothrichial, non-acid-fast, the parent form of the others. Stricker and others have insisted on the diagnostic value in doubtful, especially anaesthetic, cases of *B. leprae* in the nasal mucus. Johnson found them in the nasal mucus of 12.9 per cent. of known anaesthetic lepers, that is, the cases in which their presence is likely to be of diagnostic value, and in 52 and 43 per cent. of known nodular and mixed lepers. He concludes that nothing is gained by examination of the nasal mucus in the presence of definite clinical evidence of leprosy, and that in the absence of clinical signs, acid-fast bacilli in the nasal mucus should not be regarded as prima facie evidence of leprosy. He attaches much importance to the examination of the blood during febrile paroxysms in doubtful cases.

THE report of the Government Veterinary Bacteriologist, Southern Rhodesia, for the year 1916-17, compiled by Mr. Bevan, M.R.C.V.S., the Government bacteriologist, states that over 2,500 smears and specimens from the field and almost as many from animals under experiment at the laboratory were examined. Of the former, 120 showed the parasites of African coast fever, 125 the parasites of other diseases, and 33 specimens of serum the presence of the virus of contagious abortion in cattle. It is stated that the more general application of the principle of "short-interval dipping" has to a large extent reduced the losses due to plasmoses of cattle. In practice there would appear to be three stages in the development of a herd: (1) The pioneer stage, when imported animals cannot be used for the improvement of the nucleus of native cattle unless inoculated, and when a heavy mortality of young stock must be expected from redwater and other diseases. (2) A second stage, when by systematic dipping the veld becomes tick-free and imported stock can be introduced with impunity, and the young progeny grow up and thrive free from disease. (3) A third stage, when animals bred upon such areas being susceptible to tick-borne diseases cannot be exposed to tick-infected veld, so that the market for them becomes restricted. Until, therefore, the practice of systematic dipping becomes universal, there are certain disadvantages associated with this method. There still exists the necessity of a satisfactory method of inoculation for the protection of imported bulls exposed upon infected veld, and efforts have been made during the last ten years to discover a means of conveying immunity. An epidemic amongst pigs was found to be due to a trypanosome of the *T. pecorum* group. The administration of antimony oxide had no apparent influence upon the course of the disease.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2631, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES AND ANSWERS.

ULSTER MEMBER.—A M.P.S.I. cannot permit an unqualified assistant to dispense medicine except under the proper supervision of a fully qualified chemist. We would advise our correspondent, if his chemist should persist in ignoring his representations in this matter, to communicate with the Pharmaceutical Society (Ireland), 67, Lower Mount Street, Dublin.

INCOME TAX.

"LOCUM" inquires as to the proper method of assessment of fees received while acting for a local authority on terms of weekly notice; and as to the position of the tax officials who are sending communications through a friend's address, given by our correspondent to them some time ago.

. All salaries, fees, wages, etc., paid by local authorities are assessable under Schedule E on the basis of the current year's receipts; at the same time, if our correspondent has been acting temporarily at various places during this financial year and in the three previous years, the authorities would, we believe, deal with the whole matter on a three years' average. In the circumstances we do not see what right the assessor for the town in which our correspondent's friend resides has to demand his present address, but we suggest that, having used that address, our correspondent has probably brought himself on to the assessor's list—in fact though not in law—and that the assessor's inquiry is directed towards obtaining a more recent address to which the matter might be transferred; if so, the satisfaction of the request would seem desirable from all points of view.

B. G. R. C. is employed by the Ministry of Munitions at a Government factory hospital. He inquires whether he is taxable at the civilian rate or at the "reduced rate chargeable on Government pay."

. Our correspondent has in mind the special rate applicable to army and navy pay, to which he is not entitled. There is no difference between the ordinary civil rates of tax and the rates chargeable on Government salaries and fees other than army and navy pay.

LETTERS, NOTES, ETC.

HABIT AND CRAVING.

DR. ARTHUR KING (Wareham) writes: In your leading article on veronal (February 9th) there is a small point which is less hair-splitting and more practical than at first appears. Sir James Mackenzie, I take it, in effect says there is no such thing as a veronal habit because there is not the same craving as with morphine and the bromides, which produce their own peculiar, attractive, dreamy quiet, and that veronal is a means only to an end, while morphine has its thralldom in its means—that without craving there is no habit. Observation in not a few instances has suggested that craving and habit can be things apart, and that habit often persists after longing has died. The original act may be, no doubt, the result of desire, but every act tends to repeat itself, and, if not unduly complex, is performed automatically. "The cause of drunkenness is drink" is a statement of bald fact. If repeated vicious acts have not craving as a mainspring, the patient's cure should be almost simple, but to burke or scotch desire involves a more difficult problem.

IMPETIGO COMPLICATING SCABIES.

DR. FRANCIS CHILD (Princess Christian Military Hospital, Englefield Green) sends a letter which confirms the observations made by Major Henry MacCormac, R.A.M.C., in a paper published in the JOURNAL of February 2nd (p. 144), to the effect that many men who arrive from France with a diagnosis "impetigo" or "I.C.T." are in reality suffering from scabies, the lesions occurring frequently in parts of the body not usually associated with itch. In such cases patients who have been under treatment for impetigo for weeks will generally heal rapidly without recurrence, under treatment by sulphur instead of mercurial ointment.

ILL-TREATMENT OF PRISONERS IN GERMANY.

MRS. SONIA E. HOWE (St. Luke's Vicarage, Finchley, N.3) asks us to state that Dr. Basilevitch, one of the 110 Russian doctors who have returned from captivity, desires to be put into touch with British colleagues who, like himself, have witnessed German ill-treatment of prisoners. As no British bishop or Russian Red Cross sisters are allowed to visit the camps in which the greatest horrors are perpetrated medical men alone are in a position to give authenticated proofs of the accusations. Dr. Basilevitch has written a book of evidence collected by himself and his colleagues, which will be translated into English. Any British medical man who has been in enemy captivity is asked to communicate with Mrs. Howe.

THIRST AT SEA.

MR. MORLEY ROBERTS writes: In 1910 the idea occurred to me that death at sea from thirst when there was no fresh water could at any rate be postponed, and possibly altogether avoided, by rectal injections of pure sea-water. I founded the view on the fact that when sea-water is actually drunk it sets up reverse peristalsis, locks up the pylorus in a tonic spasm such as occurs in acute abdominal cases, and hence is not absorbed; while hypotonic and isotonic injections, though unpleasant to drink and likely to cause vomiting, serve every purpose in subduing thirst. Thirst is in practice thus avoided when malignant disease or obstruction of the oesophagus prevents deglutition. I considered that the saline not needed by the blood plasma would be excreted by the kidneys, and that the heavy work thrown on them for short periods would be unlikely to damage them. I communicated these opinions to many medical men, and even to one medical paper—not the BRITISH MEDICAL JOURNAL—in 1911, but was unable to get them published without some proof. One well-known physiologist who thought them rather interesting suggested I should try the experiment on myself. This I did not do, for reasons with which I need not trouble you. I am, however, now in a position to quote evidence that my theoretical views were sound, and Mr. R. Graham, for whose bona fides many well-known men will vouch, has kindly permitted me to adduce it. The following are the facts:

While returning to England from the United States in 1916 he undertook a fast, and while fasting injected daily two gallons of pure sea-water. During the first five days he did not take anything whatever to drink, although on the fourth and fifth day he washed his mouth out with ordinary water. He did not feel in the least thirsty till the sixth day, when he took half a tumbler of water. Such thirst as he experienced was, however, very slight. On the seventh day he drank one and a half glasses of water, although he felt he could have gone without had he chosen to do so. During this period his pulse was normal, his general condition good, his strength well maintained, and though the injections resulted in the usual evacuation, there was no tendency to diarrhoea or any other disturbance. On the eighth day he resumed his normal life. I think there can be no doubt that these facts are highly important. Even this last year, owing to the U boat campaign, English seamen have died of thirst. With a Higginson syringe as part of a boat's normal equipment, I submit that such disasters could be avoided or, at the very least, postponed, thus affording castaways a better chance of being picked up.

THE same post brought us a letter from Lieut.-Colonel Geo. WHEBBY, M.C., F.R.C.S., R.A.M.C.(T.), suggesting that "the injection of sea-water into the lower bowel, if slowly done, would give some relief and prolong life in such cases. We use saline injections in our hospital wards with great advantage and the apparatus needed is of a simple kind:—a glass syringe or a rubber tube to be used as a siphon; the nozzle and bowl of a tobacco pipe in emergency might answer. As I cannot gather from any navigator that the plan has ever been tried, I make the suggestion as above for the slow injection of sea-water as an enema for absorption."

TREATMENT OF VINCENT'S ANGINA.

DR. CASSIO DE REZENDE (Guaratatinga, S. Paulo, Brazil) writes to express his agreement with Dr. Scargill as to the good effects of the application of ordinary tincture of iodine in Vincent's angina. Of late the following course of treatment has seemed to me to be still more efficient: (a) Three or four times a day to gargle with a solution of hydrogen peroxide; (b) after every gargle to apply to the diseased spots a mixture of quinine hydrochloride with an aqueous solution of methylene blue (3 or 5 per cent.). He has followed the same line of treatment in pyorrhoea alveolaris.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

The following subscriptions to the Fund have been received during the week ending February 11th:

	£	s.	d.		£	s.	d.
Dr. Norman Walker	5	5	0	Dr. Herbert Menzies	2	2	0
Sir Alfred Pearce Gould				Miss Marjorie Monk-			
(£5 for advertising, £5				house	5	0	0
for relief)	10	0	0	Dr. Cameron Kidd	2	2	0
Dr. Alfred Cox	1	0	0	Dr. Hale White	5	5	0
Dr. W. Black Jones	1	0	0	Mrs. Duopbie	5	0	0
Mr. J. E. H. Watson	1	1	0	Dr. Hyla Greves	3	3	0
Per Sir Rickman J.				Dr. A. Hill Joseph	2	2	0
Godlee	2	0	0	Dr. H. B. Williams	2	2	0
Dr. David Rice	3	0	0	Dr. Unthoff	5	5	0
Dr. J. T. Rogers	2	2	0	Captain F. W. Jones,			
Dr. Chas. J. Lathbury	2	2	0	R.A.M.C.	1	1	0
Dr. T. W. Robbins	1	1	0	Dr. Herbert Lucas	1	1	0
Mr. Charles Ryall	26	5	0				

The Executive Committee, at its meeting on February 7th, resolved to issue a circular letter to medical men and pharmacists making an urgent appeal for subscriptions to the Fund. The allocation by Sir Alfred Pearce Gould of part of his subscription towards the necessary expenditure on this circular draws timely attention to the fact that its cost must be considerable.

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

ON NATIONAL RATIONING.

IN a letter dated February 6th, 1918, Dr. John L. Spiers of Gateshead writes: "I take most emphatic exception to the statement in your leaderette on rationing in this week's BRITISH MEDICAL JOURNAL asserting that the butchers' wealthier customers consume proportionally more meat than the working classes. From careful observations I am prepared to assert that the case is almost exactly the opposite."

* * The increased proportional consumption of meat with rising income and social position is shown in all collections of data yet published (for instance, in Mr. Rowntree's York families, the weekly "man" consumption was 2 lb. 4 oz. in poor families and 4 lb. 5 oz. in servant-keeping families). As we have repeatedly pointed out, the consumption of meat by the hand-working classes increased last year, but, for obvious economic reasons, the general proposition is, we think, still valid. Indeed we have never before seen it challenged.

DETERMINATION OF SEX.

DR. T. S. SHELTON (Chester) writes: The following, which is a footnote in vol. i of Lecky's *History of Rationalism in Europe*, may be interesting to some of your readers: "Melancthon deals, in a tone of the most absolute assurance, with the great question of the cause of the difference of sex: 'Mares nascuntur magis in dextrâ parte matricis, et a semine quod magis a dextro testiculo oritur. Fœmellæ in sinistrâ matricis parte nascuntur.' (Melancthon, *De Animâ*, p. 420.) This theory originated, I believe, with Aristotle, and was afterwards repeated by numerous writers."

THE STERILIZING OF HYPODERMIC SYRINGES.

DR. F. E. TAYLOR (London) writes: Dr. Lyon Smith's method of sterilizing hypodermic syringes (January 26th, 1918) is described as simple and convenient. The following is also a simple, rapid, and convenient method. I have given several thousand hypodermic injections with syringes so treated, without a single failure to maintain asepsis. The barrel is withdrawn and syringe and barrel are kept immersed until required in a two per cent. solution of bacterol, which forms a clear transparent non-greasy solution. Steel needles are similarly kept immersed in phenol-xytol, consisting of one part of crystallized phenol dissolved in two parts of xytol, in which the needles do not rust. To remove the phenol-xytol before use, the needles are rinsed through with alcohol and ether (equal parts), and then with the two per cent. bacterol in the vessel in which the syringe is kept.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

NOTES ON PENETRATING WOUNDS OF THE BRAIN.

BY

HARVEY CUSHING, M.D., Hon. F.R.C.S. Eng.,
DIRECTOR U.S. ARMY BASE HOSPITAL No. 5.

In the later part of July three contiguous casualty clearing stations in a certain army area were designated as a centre for the reception of all wounds of the head occurring during an expected period of military activity.

To one of these hospitals the writer was attached for three months, and on taking up his duties endeavoured to make an estimate of what might be:

1. The operation mortality at all three hospitals combined.
2. The proportion to one another of simple scalp wounds, cranial injuries without dural penetration, and cranio-cerebral wounds, respectively, among all the cases forwarded from the field ambulances on the front concerned, with an initial diagnosis of "head or scalp wound."

Toward this end a combined record was made of all cases admitted with the above general diagnosis during the first two weeks of the three-month period, verifying it and particularizing it in each case whenever an operation or other circumstance rendered this possible. This actually proved to be possible in only about half the total, as in times of pressure many of the lighter cases were of necessity immediately evacuated. It is probable that the majority of the wounded, thus passed on without operative investigation, had injuries confined to the scalp, or to the scalp and cranium, though it must be admitted that among walking wounded it is not uncommon to find men with penetrating wounds of the brain.

The net results of the study were as follows: Taking as 100 the total number of cases admitted with an initial diagnosis of some form of "head wound," the percentage with dural penetration was 23.5. Taking the verified cases alone, the percentage with dural penetration was 49.3.

Of these 49.3 per cent. verified cases approximately one-third died without operation, their injuries being either of extreme gravity or multiple. Of the remaining two-thirds, all were submitted to operation, and exactly half of the patients subsequently died, thus giving the generally accepted 50 per cent. operation mortality for wounds of this type.

The foregoing figures relate, as has already been indicated, to all the three hospitals during the first two weeks of the three-month period. For comparison the following figures covering the whole three months may be given for the cases that came under the supervision of the writer's team. Of the cases submitted to operation, 10.9 per cent. proved to have merely scalp wounds, 23.7 per cent. cranial wounds with intact dura, 60.7 per cent. cranial wounds with dural penetration, and 4.5 per cent. bursting fractures of the cranium but with the scalp and dura both intact. In most of the cases with simple scalp wounds or depressed fractures the condition had been such as to lead us to anticipate finding a dural penetration.

During the initial two weeks to which reference has

been made, the operation mortality for the writer's own team was above the average figure for all the hospitals together. This may be accounted for in some measure by the fact that during this period, as also during the entire three months, wounds of the more serious type were deliberately selected from among the cases retained at the hospital. This is indicated by the relative height of the percentage of cases with dural penetration (60.7) as compared with the corresponding percentage (49.3) for the whole of the verified cases during the first two weeks.

It was with the penetrating wounds, in short, that we were chiefly concerned, and a serious effort was made to see whether the accepted mortality figure of *circa* 50 per cent. could not be lowered by improvement in technique, and a more intimate supervision of each individual case from start to finish. Careful records have been kept of the 225 cases which came under the care of the team: of these 6 died without intervention, the remaining 219 were operated upon, and 133 proved to have dural penetration. The net results are best shown by dividing these 133 cases into thirds roughly corresponding with each consecutive month of service.

First	44 cases with 24 deaths = 54.5 per cent.
Second	44 " 18 " = 40.9 "
Third	45 " 13 " = 28.8 "

These percentages, which are practically end results, for no cases were evacuated until they had passed the stage of conceivable complications, are sufficiently encouraging to justify the hope that a still further lowering of the mortality may be attained, and that in an advanced hospital 75 per cent. of recoveries is not too large a figure to be set as a goal.

The improved figures do not mean that more favourable cases were selected as time went

on, for, on the contrary, as the results improved the general tendency was to undertake operations on more and more unpromising injuries, particularly of the cranio-cerebro-facial type, in many of which radical measures in the earlier weeks of the service would hardly have been attempted. Indeed, on two occasions six consecutive deaths occurred in the series, due to an uncontrollable gas encephalitis which had become established in cases "lying out" for two or three days after a battle.*

* In computing these mortality figures no cases whatever have been eliminated, even when the ultimate cause of death—including tetanus, gas poisoning, complications from wounds elsewhere, spinal cord transection, and so on—was obviously unrelated to the cranio-cerebral injury. Should one begin to eliminate these complicated cases in making out his mortality percentages the figures would lose all their comparative value, for there can be no agreement as to what conditions may justifiably be excluded.

Detailed mortality figures for penetrating wounds of the dura are rarely given, and when given are variously computed. This is unfortunate, for it is only by comparison with such estimates that one can tell whether his end results are better or worse than the average.

That the mortality percentage is high is commonly admitted. Colonel Sargent has made the statement in an unpublished address that "in the first two years of the war 45 per cent. of patients with perforating (penetrating?) wounds operated upon in field ambulances and casualty clearing stations died in the base hospitals." If, therefore, nearly half of the cases operated upon succumbed at the forward hospitals before evacuation, as is more than likely, and nearly half of those evacuated subsequently died at the base, the total mortality must have been in the neighbourhood of 70 per cent.

Colonel Gray, however, in his paper (BRITISH MEDICAL JOURNAL, February 29th, 1916) states that in 392 cases (excluded in the base hospitals at R—there were 58 deaths, a mortality rate of 14.8 per cent. He adds that if 12 "hopeless" cases which died within forty-eight hours of admission are excluded from the series, the mortality is only 9 per cent. This estimate is lower than the mortality figures at a casualty clearing station, for the non-penetrating cranial wounds

FIG. 1.—Flap incision for penetrating wound of anterior temporal region. Gutta-percha drain through unexcised wound. Condition at first dressing after forty-eight hours, when sutures and drain should be removed.

The surgical care of the wounds of modern warfare is very much of a specialty, and, no matter what may have been an operator's previous training and experience with

traumatic surgery, he finds himself ill prepared for his tasks; indeed, his fixed habits of work acquired in the favourable surroundings of a civil hospital and his unfamiliarity with infections may prove a handicap rather than an asset. This applies possibly even more to the surgeon who in civil practice has specialized in a comparatively narrow field than it does to the surgeon whose work has been more generalized.

However, during the three-month period an operation, with certain technical devices applicable to the average penetrating wound, was gradually evolved; and as the lowered mortality percentages of the later series can be ascribed to it, the method may deserve description. Aside, possibly, from the principle of track suction there is nothing original about the procedure, nor are the instruments new, though they do not seem to have been commonly utilized, at least in the British overseas hospitals.

The main features of the procedure lie:

1. In the removal *en bloc* rather than piecemeal of the area of cranial penetration.

2. In the detection of the indriven bony fragments by catheter palpation of the track rather than by the exploring finger.

3. In the suction method of removal of the disorganized brain, thereby cleansing the track of the so-called pulped or devitalized tissue, whose retention, as is the case with dead tissue anywhere, favours infection.

4. In the use of dichloramine-T in oils as an antiseptic particularly suitable for infections in the central nervous tissues.

In addition to these more essential features of the performance, the routine pre-operative neurological study of the case stereoscopic x-ray negatives, the shaving of the

entire scalp, the invariable use of local anaesthesia, pre-ferential radial (tripod) rather than flap incisions, foreign body extraction with the magnet when possible, closure of

the wounds with buried sutures in the galea, the dressing of all serious cases in the operating room rather than in the wards—all these steps, though less novel, were, nevertheless, contributory to the successful outcome of the more severe cases.

1. THE ORGANIZATION OF THE OPERATING TEAM.

At a casualty clearing station, where at times wounded may be admitted in great numbers, team work, particularly when

serious cranial procedures are to be covered, is of prime consideration. At best most of the more critical operations deservedly require upward of a two-hour period; and as one team, eliminating all delays, can hardly expect to do many more than eight major cases a day, the greatest possible economy of time must be practised.

Each team should be provided with an extra wooden table, indeed, if there is sufficient space, with two extra tables or trestles to support the stretchers. In this way a series of cases can be continually fed in, and the patients be more or less under the surgeon's eye while the neurological examination, the x-ray exposures, the shaving of the scalp, the giving of the primary drug and the novocainization of the field, all of which is time-consuming, can be carried out, and the next patient be ready to supplant the preceding without the usual loss of time between operations. An extra table is almost as valuable to a team as an extra medical officer.

2. THE NEUROLOGICAL EXAMINATION AND THE X RAY.

It is generally conceded by the majority of those

who have written on the subject that serious cranial operations should not be undertaken without a preliminary neurological study. It unhappily is not universally

It would be desirable if we could all come to record our cases from the same standard, whether from a forward or base hospital, and as a temporary basis for comparison, it may be suggested that all cases of dural penetration, regardless of complicating factors, be included in future reports. Only by the establishment of some accepted standard will it be possible to compare the efficacy of operative methods advocated by different individuals, or for one individual to appreciate an improvement in his own results as he gains experience.

FIG. 2.—Unilateral occipital flap for penetrating wound of right cerebellum. Wound of entrance unexcised. Condition on sixth day. Sutures should have been removed earlier. Those of silkworm-gut are deeply cutting; those of black silk remain dry.

taken by them-selves. Abadie's statistics (*Presse Médicale*, September 25th, 1916, p. 421) for 102 cases with opened dura gave 56 per cent. mortality. Cunéo (*Presse Médicale*, July 6th, 1915, p. 229) estimated a mortality of 60 per cent. for cranio cerebral wounds. Lapointe's figures (*Journal de Chir.*, 1915, xiii, 241) for all cranial injuries treated at a forward hospital early in the war were 53.75 per cent. Seneert's figures, also from a hospital at the front (*Lyon Chirurgical*, March-April 1916, T. xiii), including the 24 deaths recorded as occurring after evacuation are in the neighbourhood of 63.5 per cent.

observed. Without such an examination and the careful recording of the positive neurological findings, an operator can never be sure whether the paralyses which are subsequently observed were pre-existent, or were due to or increased by his surgical manipulations. Certainly any immediate post-operative increase in pre-existing symptoms, whether in the sphere of speech, vision, motion or sensation, should be regarded as an evidence of faulty technique. Moreover, if pre-existing palsies, the presence and grade of which, except in the profoundly unconscious cases, can easily be determined, fail to subside with considerable rapidity, the fact can be interpreted as an evidence of an incomplete operation, and complications may be anticipated. Furthermore, the question of justifiable opening of an intact dura in the course of an operation, or the need of a secondary operation for symptoms of a presumptive abscess may depend entirely upon the original neurological symptoms and their post-operative increase or subsidence.

Stereoscopic radiograms are of course invaluable, not only for the

FIG. 6.—Cranial perforator (seven-eighths natural size).

localization of a penetrating missile, but for the detection and enumeration of all indriven bone fragments.

3. THE PREPARATION OF THE SCALP.

The entire scalp should be shaved—no easy task when an uncropped head of hair has become caked with blood and mud. A close haircut before going into battle, and the application of a warm soap poultice at a field ambulance would not only help toward preventing infection but would also make the preparation for these operations a less arduous matter. The partial shaving so commonly employed is undesirable, for one can rarely tell beforehand how extensive may have to be the incisions necessary for closure.

Shaving of the scalp is an art and requires a good barber, but it is indispensable to a proper preparation of the field. The preliminary use of clippers is to be avoided, for they leave the scalp covered with short hairs difficult

to remove. As a final step the mere sponging with alcohol and a mercuric bichloride solution is preferred to any of the staining solutions such as iodine or picric acid, which are apt to leave the epithelium scaly or encrusted.

4. THE ANAESTHETIC.

During the shaving of the head, possibly an hour before the patient's turn will come, a sedative is given, a third of a grain of omnepon usually being sufficient, though this may be repeated if the patient is very restless or obstreperous. Then fifteen or twenty minutes before the operation, in the lines of proposed incision,

the scalp is infiltrated with a 1 per cent. novocain and adrenalin (15 drops to 30 c.cm.) solution, injected in the sub-aponeurotic layer.

There exists a difference of opinion regarding the relative merits of a general *versus* local anaesthesia for cranial operations. The writer confesses to an original prejudice in favour of inhalation narcosis, but experience has led him completely to alter this view.

General narcosis increases intracranial tension, which exaggerates the difficulties of an operation already difficult enough. It increases bleeding from the scalp, which, with the adrenalin-novocain solution, is rendered negligible. It encourages the use of rougher methods, which a patient under local anaesthesia would not tolerate, and which therefore are in all likelihood

harmful. It encourages speed, which is to be decried if employed at the expense of delicacy. It leaves many patients, particularly those with threatened respiratory difficulties, in a condition in which inhalation troubles are prone to occur.

Until recovery from a general anaesthetic is complete every patient should be under close observation, and this, at

a casualty clearing station at least, is an impossibility. It is very rare, and then only in the case of semi-conscious patients or those with restless irritability, that the operation cannot be carried through under local anaesthesia, though this necessitates more gentle manipulations than

FIG. 5.—A typical tripod incision (after five days) for penetrating wound in the mid-occipital region. To show character of wound healing when flaps are held by buried Galen sutures and superficial sutures are removed early.

FIG. 8.—Montonovesi linear cutting forceps to follow burr (seven-eighths natural size).

these usually employed, particularly during the process of removing the area of cranial involvement.

5. THE PLOTTING OF THE INCISION.

Many procedures have been advocated. They necessarily vary greatly, according to the likes and practices of different surgeons, and for different wounds in different areas. As in plastic operations elsewhere, success in closing defects is the offspring of ingenuity and experience.

Flap incisions, which leave the wound in the centre of the flap, are suitable for some of the penetrating wounds through muscle in temporal or suboccipital regions (Figs. 1 and 2) but for ragged or gutter defects over the vault what may be described as a "tripod" (Fig. 3), or for more extensive defects a "three-legged" (Isle of Man) incision (Fig. 4) has come to be the preferential one in the writer's hands.

When the three flaps are reflected, ample exposure of the field necessary for the trepanation is afforded, and if the flaps have been sufficiently undermined in the subaponeurotic layer the corners may usually be brought together without undue tension. It is the writer's custom to bring the edges of the galea together by a layer of buried fine black silk sutures, so that the external sutures used to approximate the cutaneous edges may be safely removed on the second day. The heavy silkworm-gut sutures usually employed in a single layer, particularly if tied under tension, rapidly cut through and make an uncomfortable wound, an ugly scar, and encourage infection.

These tripod incisions (Fig. 5) with the focal point of the closure directly over the dural defect, have come to be preferred to the switching of a flap over the centre of the field, owing to certain trying experiences with an infected hernia cerebri in cases in which the track of the missile has been incompletely cleansed. The surface of such a fungus is much more difficult to treat when partly overlain by a flap than if it were allowed to present in the centre of radiating incisions.

6. THE TREPANATION EN BLOC.

The method usually advocated is to make with a trephine an opening to one side of the depressed area, and with rongeurs to nibble away fragments of bone until an opening of sufficient size is secured. Even with rongeurs of the best pattern this necessarily means not only working across an infected field, but the jar of breaking out the fragments with the ordinary forceps entails an amount of trauma which is more than a patient not under a general anaesthetic will tolerate. Moreover, there are certain areas of the skull where even the most expert runs a risk of cutting the dura when using a trephine.

A far more simple and satisfactory procedure is to encircle the area of depressed bone with a number of small punctures made with a perforator and burr* (Figs. 6 and 7),

and then to connect these small primary openings with a linear cut, thus excising the soiled area of depressed fracture in the bone, just as the soiled scalp wound is excised. The linear cut may be made with the instruments designed by De Vilbiss or Dahlgren, but a far more effective tool for the purpose is the Montenovesi cranial forceps (Fig. 8). This instrument, when of proper pattern, inflicts far less

jar, its beak can be inserted through a smaller hole, and with it a corner can be more easily turned. When the area has been encircled, the bone disc is tilted out in one piece (Fig. 9).

The depressed fractures thus disclosed are of two main types: (1) With the fragments still adherent (Figs. 9 and 10), or (2) with the fragments completely detached and "showered" to a greater or less depth into the brain (Fig. 11). The preservation of the mosaic of fragments in the first type is often a matter of importance, for when incomplete it is evident that one or more fragments are indriven and must be secured before the operation can be regarded as complete.

Particularly when working over a sinus is this method of bone removal to be favoured, for if the sinus happens to be torn by a bony spicule, as it so often is, the withdrawal of this particular spicule before complete exposure of the area may provoke haemorrhage which may be very difficult to control. On the other hand, with the entire field exposed by the careful tilting outward of the entire block in one piece (Fig. 9), the bleeding point is fully bared, and can be quickly and easily sealed, preferably by a muscle graft.

7. THE TREATMENT OF THE TRACK.

In penetrating cases the proper and thorough cleansing of the track is the most important step of the operation.

In the earlier cases in the series it was the custom to enlarge the dural opening by cutting away its torn and ragged margin. This has since been abandoned, for it is a procedure which often causes troublesome bleeding from the unavoidable fresh division of the vessels in the torn pia arachnoid, for the two membranes quickly adhere after the injury, a matter of hours rather than days, as is often stated. Even though bleeding from these vessels can be readily checked by the placement of "silver clips" (Fig. 12), it has been found unnecessary to practise routine re-

moval of the dural margin, for it does not appear to be a source of infection which need be seriously feared.

Much more serious is the retention of the disorganized and devitalized cone or cylinder (Fig. 13) of cerebral tissue which lines the track, and in which the indriven bone fragments are embedded. Though extraction of these fragments is advocated, no special emphasis has been laid on the desirability of thorough removal of the pulped tissue which surrounds the pathway of the missiles, and which, like devitalized tissue of any kind, is a soil favourable to the growth of organisms.

As Colonel Gray has suggested, if the patient is encouraged to cough, clots and cerebral debris oftentimes

FIG. 9.—Showing the turning back from the mid vertex of an area of depressed fracture (actual specimen), disclosing a dural laceration with tear to the margin of the sinus.

FIG. 10.—Specimen of depressed fracture removed *en bloc*, showing adherent fragments with mosaic complete (natural size).

* These instruments are almost as ancient as the trephine. Though commonly ascribed to the late Dr. Doyen, the brace and bit and various forms of burr were fully pictured by Barengar in the sixteenth century.

may thus be expressed, and some have employed gentle curettage or irrigation; but if a finger is introduced in the track for purposes of exploration, the disorganized and soiled cerebral tissue lining its walls will be crowded inward, whereas every effort should be made to get it out.

Almost from the outset reliance was placed on the use of a flexible, soft-rubber catheter as a means of determin-

FIG. 11.—Specimen of cranial gutter wound removed *en bloc*. No fragments adherent, all having been detached and driven into brain.

ing the exact direction taken by the missiles, whether a metallic body, or bone fragments, or both (Fig. 13). Without the production of additional trauma one may investigate in this way even the narrowest track, and it will be found that the presence and situation of any indriven bone fragments can be detected with almost as great delicacy as by direct palpation.

By attaching to the end of the catheter a Carrel-Gentile glass syringe with its rubber bulb (Fig. 14) it is possible to suck up into its lumen the softened brain, which can then be expelled from the catheter as paste is expressed from the orifice of a tube. The process should be repeated until the cavity is rendered as free as possible of all the softened and infiltrated brain. It will be found that the adjoining normal cerebral tissue, unaffected by the original contusion, will not be drawn into the tube by the degree of suction which can be applied by the average rubber bulb.

Not infrequently bits of bone come away in the eye of the catheter, and on one or two occasions a small foreign body has thus been withdrawn. Meanwhile, as the track becomes clean and the tension and tendency of the brain to herniate subsides, it is possible with delicate duck-billed forceps to pick out from the track one by one the bone fragments, whose depth and position can be determined by the unmistakable sensation they impart to the catheter, which thus supplements the information given by the x-ray plates. The technique of the performance will quickly be acquired by any one who may wish to put it into practice.*

Any procedure is capable of being abused, and even a soft flexible catheter may possibly be forced to do damage. Even those who advocate digital exploration admit that damage may be done thereby unless the greatest care is exercised, but

* In not a few cases in the series the missile and bone fragments have been driven through into the ventricle, and in the process of suction the cerebro-spinal fluid spaces have been sucked completely dry. These ventricular penetrations have been met with in twenty-five cases, and it is by no means as desperate a condition as is generally supposed. Many cases with opened ventricle, when treated in this way, have made perfect recoveries, as will be related in a more detailed communication which will permit of case reports.

we must recognize that the surgical profession contains its Little Jack Horners, and it is better, on the whole, for all of us to keep our fingers out of the brain so far as possible.

8. PURPOSEFUL INCISION OF THE DURA.

This procedure, in the case of the usual subtemporal decompression through an intact scalp, need not concern

FIG. 12.—Showing the method of placing silver clips on the vessels of dural or meningeal margin.

ns, but when performed in the area of a dirty wound it is a different matter. Under these circumstances it must be undertaken with great hesitation, and only in those cases in which the neurological symptoms indicate a serious local loss of function, or in which the exposed and undamaged dura is tense and evidently overlies a clot or severely contused area.

If the dura is opened under these conditions, if the disorganized area is washed and sucked away until normal tension is restored, and if the membrane is then accurately closed with delicate fine black silk sutures passed on curved French needles, there is practically no risk of infection. Needles with cutting edges and heavy suture material are unsuited to this delicate procedure.

There can be no doubt but that the period of convalescence and its attendant discomforts in this particular group of cases can be greatly lessened by opening the dura, but if the surgeon has any doubts of his technique or of the cleanliness of the wound, he had far better give the patient the chance of recovery afforded without incising the membrane.

9. RETAINED MISSILES.

It goes without saying that it would be the ideal treatment, at a primary operation for a penetrating wound, if the foreign body could always be removed. Otherwise the operation must be regarded as incomplete, with a far greater likelihood of subsequent abscess formation than if removal of the missile has been accomplished. It is equally true that foreign body extraction, no matter how desirable as a means of avoiding these possible secondary complications, should never be forced to the point of increasing the damage to the nervous tissues already done by the penetration. Some say "avoid infection at any cost"; others "better a fatality from infection than the certainty of perpetuating paralysis." Between these two schools one must decide in the individual case.

It is well known that many, even sizable bodies—a shrapnel ball, for example—may be retained without provoking symptoms, but even so, the writer has known of

FIG. 13.—Diagram to show the insertion of a catheter in the track of a penetrating missile.

abscess formation around such a missile first giving evidence of itself a year after the injury. The middle ground position is the safest one—namely, always to extract a foreign body if it can be accomplished without increasing the damage already done.

This discussion applies solely to deeply implanted missiles, for all agree that superficial and easily accessible ones should of course be removed. Extraction with a magnet is the only justifiable method applicable to deep-seated bodies and can often be accomplished after suction of the track in the usual method by gently sliding into it, to the proper depth, a French wire nail with rounded point. Contact with the proximal end of the nail is then made with a portable electro-magnet, which need not be a weight greater than can be easily handled, and if the foreign body is magnetizable and proper contact secured it will be withdrawn along its own track of entry.*

All of the foreign bodies from which cultures were made gave a growth of organisms—usually streptococcus, staphylococcus, or some gas-producing bacillus.

10. THE USE OF ANTI-SEPTICS.

The use of watery solutions of antiseptics in the brain is disappointing, for they lead to oedema with swelling of the tissue and an increased tendency to herniate. It was not until Dakin's dichloramine-T in eucalyptus oil came to be utilized as a routine during the latter weeks of our service that there was a notable diminution in the number of infections.

It is true that the technique of the procedures had greatly improved at this time, and true also that we can record no thoroughly conclusive bacteriological studies, though cultures of many of the wounds and foreign bodies were made. With the dichloramine-T, in not a few cases in which an infected foreign body was removed and in which bone fragments as well gave an abundant growth, no symptoms whatsoever followed closure of the wound without drainage. In two instances the cultures showed the presence of the pneumococcus in the ventricular fluid, and the only patients in the series who have recovered from active gas infection of the brain were treated with this drug.

As the terminal step of cleaning out the contused pathway of the missile a small amount of the oily solution is injected along the course of the track through a small catheter, and, just before final closure of the scalp, the dural surface of the wound is moistened with the same solution.

CONCLUSION.

This bare recital of an operative method for a certain type of the many wounds which occur in warfare makes dull reading. It is hoped that it will nevertheless carry some suggestions to others who, like the writer, without preliminary instruction, may, by force of circumstance, have to undertake similar tasks. Much admirable work directed toward the improvement of cranial operations has been done by surgeons in the allied armies—in the British Forces notably by Sargent, Gray, Anderson, Grahame, and Wagstaffe. Unfortunately, however, there have been few, if any, detailed reports of a series of cases, either from front or base, and the underlying principles of treatment

* The extraction was successful in eleven cases in the series in which the missiles would otherwise have been inaccessible. It would have been preferable to place the interposed nail in exact contact with the foreign body under the direction of a fluoroscope, but our situation did not permit of this. The procedure is capable of great development, and next to the eye the brain is the most favourable place for employing the magnet.

of these penetrating wounds has been the source of some disagreement. A surgeon naturally becomes wedded to the particular procedure which he happens to have developed and is more likely to succeed therewith than by adopting the methods of others.

There can be little doubt but that, as is the case with thoracic, abdominal, and joint injuries, the earlier a cranial operation is performed the less likelihood there is of sepsis. The mortality, however, in a hospital near the front is, in the natural course of events, almost certain to be greater than the mortality of operations for similar conditions at the base, for delay always serves to eliminate a certain percentage of the more desperately injured. For this all allowances must be made.

A distinguished surgeon once seriously advocated operating upon typhoid perforation in the second rather than in the first forty-eight hours, because the collected statistics had shown that a larger percentage of cases operated upon in the second forty-eight hours recovered. In the difficult task of dealing honestly with statistics fallacies of this kind at least can be avoided.

Acknowledgements.

There are many obligations to acknowledge—to General Bruce Skinner, to Lieut.-Colonel C. I. Ellis, to Captain F. A. Roper for his helpful x-ray studies, to Captain Archibald Leitch for his many bacteriological observations, and to those

who from time to time were assistant members of the surgical team on whose shoulders fell the larger part of the work.

NOTE ON THE EXTRACTION OF A FOREIGN BODY FROM THE BRAIN.

BY

CAPTAIN H. H. RAYNER, F.R.C.S., R.A.M.C.(T.),
HONORARY ASSISTANT SURGEON TO MANCHESTER ROYAL INFIRMARY,

AND

CAPTAIN A. E. BARCLAY, M.D.CANTAB., R.A.M.C.(T.),
MEDICAL OFFICER TO X-RAY DEPARTMENT, MANCHESTER ROYAL INFIRMARY.

THE damage necessarily done to the brain structure in the removal of a foreign body, coupled with the fact that experience has shown that fragments lodged in the brain may give rise to very little disability, argues for leaving deep-seated ones in position until such time as it becomes evident that their presence is the cause of the symptoms and that removal, if it can be effected, will lead to an improvement in the patient's condition. The following is a report of a case in which the attempt to remove a foreign body from the brain was considered to be indicated and was justified by the result.

History of the Case.

T. K., a man aged 20, was wounded on February 7th, 1917. The note from the casualty clearing station was: "Several small wounds in neck and back of head. Semi-conscious and suffering from shock. Vomited on the way down to the casualty clearing station. X-ray report stated that there is a small foreign body in the brain and that there is some damage to the occipital bone." He was kept in the casualty clearing station and base hospital in France for seven weeks and improved considerably; he was then transferred to England. On admission to the 2nd Western General Hospital his condition was poor; there was marked mental dullness, slowness and hesitancy of thought and speech, and he was somewhat childish mentally. He could not sit up for more than a few

FIG. 14.—Sketch illustrating the method of suction of the track of a penetrating wound.

minutes and suffered from intense headaches. He seemed to have some difficulty in opening his eyes and in bringing his mind to bear on anything. The tendon reflexes were all increased in the left arm, and there was definite weakness of the left arm and leg. There was slightly increased knee-jerk and very marked ankle clonus. The signs and symptoms all suggested a sub-cortical lesion in the right Rolandic area, and the x-ray examination confirmed this view, a foreign body being located in the suspected region. For three months he was kept under observation and symptoms became more marked. Any effort was followed by marked clonic spasms, and he was quite unable to sit up. He complained of a burning pain over the right side of the head.

The patient knew that he was getting worse both mentally and physically; he was therefore transferred to the Manchester Royal Infirmary for investigation and consideration as to the possibility of operative interference. He was again x-rayed and the foreign body was localized as 2 in. deep from the scalp beneath the Rolandic area of the right side; the damage in the occipital region was no

FIG. 1.—Radiogram showing position of foreign body, A.

longer noted in the x-ray plates. In view of the fact that the patient had steadily become worse since admission, it was decided to attempt the removal by means of a special instrument described by one of us (A. E. B.) before the Electro-therapeutic Section of the Royal Society of Medicine.¹

The Operation.

On June 26th, 1917, the foreign body was relocalized as 2 in. deep and a skin mark was made on the right parietal region just before the operation in the theatre (by H. H. R.). The position of the skin mark corresponded to a point about half an inch behind the lower third of the fissure of Rolando. The fragment was small, but it could be seen on the screen fairly well. The patient was then anaesthetized. The bone was marked through the skin mark by a fine drill and then the flap was reflected. A one inch trephine was then used, taking the bone mark as the centre, and the opening enlarged slightly above and below. In order to assist in the repositioning of the patient on the x-ray couch, small screws were put into the skull on either side of the opening.

The patient was then taken to the x-ray department and the head placed in exactly the position in which the skin mark had been made, the shadow of the foreign body falling midway between those of the two small screws. A small horizontal incision, three-quarters of an inch long, was then made in the dura, and the point of the extractor placed in position (by A. E. B.). With the lights out, the extractor was then manipulated so that the shadows of the fragment and of the points of the extractor fell exactly in the middle of the small fluorescent screen attached to the instrument. With the lights up, the point of the extractor was allowed to descend almost to the depth of the fragment (2 inches), a small band of rubber tube having been placed on one of the blades to mark this distance. Then, with lights off, the blades were gently opened to see that the shadows of the fragment and the extractor points still corresponded

to the centre of the fluorescent screen. Seeing that the direction was correct, the blades were allowed to descend to the full length, and very gently moved about to "feel" the foreign body. Almost at once the bell attached to the instrument gave a slight ring, showing that the metal had made contact across the blade points, and that by raising the points very slightly, then opening sufficiently and descending, the fragment should come in between the jaws of the extractor. This manipulation was carried out, and the shadow was again seen between the blades. On closing the blades the bell at once rang continuously, showing that the fragment had been caught. With the lights on, the instrument was gently withdrawn, and in the middle of the clot of blood that came away was the small foreign body.

The patient was then taken back to the operating theatre, where the incision in the dura was brought together and the opening in the skull closed by replacing the piece of bone.

A small quantity of clear cerebro-spinal fluid came away when the extractor was inserted to its full depth, suggesting that the fragment lay in the lateral ventricle, and this was again suggested on examination of the fragment; it was partially covered by a deposit of what appeared to be lime salts.

From measurements of the skull, the foreign body lay slightly over half an inch from the mid-sagittal plane.

In the x-ray department it took perhaps five or ten minutes to reposition the head accurately; the extraction of the fragment occupied about three minutes. The slight extent of the disturbance to the brain may be judged by the fact that there was no paralysis, even on the following day.

FIG. 2.—Radiogram showing actual size of foreign body.

After-History.

The shock of the operation was not as severe as expected, and even on the following day he could move both the hand and foot fairly well. There was no paralysis of any part and within a week the power of the grip was as good as before the operation. Recovery of power continued and the mental condition became very much clearer: it was evidently less effort to think, and the patient himself stated that he felt that he was getting better. He was able to sit up in bed without any ill effect, and the clonic tremors were less frequent and not so easily brought on. The wound healed rapidly, and the trephine disc united to surrounding bone firmly. A few weeks after operation he was able to stand and walk a few yards with assistance. On August 30th, 1917, he was transferred to Dr. Macmillan at Moorlands Red Cross Hospital, but the journey in the ambulance seemed to cause a setback for a time. Attempts to stand brought on the clonic spasms, which were also induced even in bed by slight causes. The grip was less strong, and there was very slight paresis of the facial muscles. Improvement has gradually taken place, and he is now very much in the condition he was in before he was transferred except that the mental condition is now much sharper, and there is less hesitancy in speech and thought. There is no trace of facial paresis, the grip is fairly strong, and he can walk about the room with assistance. He is evidently recovering quite satisfactorily though slowly.

The Extractor.

The extractor is made like a pair of dental forceps, the jaws being about 1½ in. apart when closed. Above the jaws is fitted a small fluorescent screen. Beaks or blades are fixed at right angles to the jaws and meet at the points, but are insulated from one another by a small fibre block let into one of the blades, which is made slightly longer than the other (see Fig. 4). For brain work the blades are thin and close together, the point of the longer blade being rounded. For the removal of foreign bodies from ordinary tissues stronger blades are used, the point being fashioned like a blunt dissector so that the instrument can dissect, and, by opening the blades, separate its own way down after the skin incision has been made. The blades are connected with an electric bell through a relay that is specially fitted in order to avoid stimulation of structures

when contact is made. When the blades are brought into the correct relationship with the foreign body—that is, with the longer blade alongside and the shorter blade

FIG. 3.—Diagrammatic view of the instrument. A, Screen holder and contact of the insulated blade; C, insulated blade; D, block of fibre on insulated blade; E, connexion bell circuit.

touching the top of the fragment—contact is made and the bell rings. This indicates that by raising very slightly and opening the blades the foreign body can be picked up without any intervening structures being also caught.

Protection, additional to that of the diaphragm, tube, box, etc., is afforded by a sheet of heavy x-ray proof rubber with a 3-in. hole in it that is placed either above or below the patient.

FIG. 4.—Large view of the points of the blades of the extractor, showing how contact is made by foreign body across the points.

The use of this instrument is not easy; like other surgical instruments, it requires practice. It also requires experience in the interpretation of x-ray shadows. When the foreign body can be seen, it looks so simple to pick it up with the points of the extractor, which can also be seen in the fluorescent screen. And it is simple, provided that the operator recognizes that it is absolutely essential to make an *exact* start directly over the foreign body and move the points of the extractor *exactly* in the line of the rays—that is, straight

to the foreign body, correcting his direction as he proceeds towards it.

Only certain cases are suitable—that is, those in which access can be had to the foreign body directly in the line of the rays, and through soft structures, or with the assistance of a trephine, as in this case. Old-standing aseptic cases, surrounded by a fibrous capsule, are not suitable for extraction.

It is not an instrument for anyone to use—it involves exposure to x rays, and must be used by or in co-operation with a competent radiologist, who is experienced in radio-therapeutics, and who knows where the danger zone from x-ray dermatitis begins, and how to protect not only the patient but also the operator.

ON THE INFLUENCE OF MUSCULAR EXERCISE ON LONGEVITY.

BY

SIR HERMAN WEBER, M.D., F.R.C.P.

To promote longevity all the systems and organs of the body ought to be kept in a healthy condition, and prevented from decaying as long as possible. We must not attend to one of them alone, but to each and all of them, must endeavour to keep them all sound and vigorous, make them assist one another, and work together in harmony.

In the present paper I intend to show the principal features of the influence of the muscular system on the functions of the other systems and on the life of the whole organism.

The contraction of the muscle, as shown by Professor Ludwig, Sir Lauder Brunton, and Dr. Oliver of Harrogate,

causes dilatation of the arterioles, capillaries, and lymph spaces, allowing more oxygenized blood to flow to the muscular fibres, which abstract from it what they require for their nutrition and let the remainder, together with the used-up material, pass partly into the veins, partly into the lymph spaces and the lymphatic vessels. By this process the muscle is nourished, the products of decomposition are removed, metabolism is promoted, and heat is produced. In addition, the small blood vessels, through their increased action, are kept in a healthy condition. We may go further and say that the spheres of the brain which initiate the contractions of the different sets of muscles, are likewise favourably influenced, for an increased flow of blood is attracted to them by their work and the blood vessels are forced into greater activity, by which their own coats as well as the brain substance are nourished.

Walking Exercise.

The most natural of all muscular exercises, as pointed out by Hippocrates, is walking exercise. A great part of all the muscles of the body is activated by it; the action of the heart and respiratory organs is increased; the blood is passed with greater force from the heart into the blood vessels of the body, which are obliged to contract more vigorously, carry more blood to the different organs of the body, nourish the latter, and are themselves nourished through their work. By the contraction of the muscles of the legs more blood is attracted to them, and is squeezed out from them into the veins and lymphatics and carried to the heart, which is forced to contract more vigorously. The pumping action of the heart thus induced strongly assists the circulation of the blood and lymph in the abdominal organs, and is helped in this by the more powerful contraction of the diaphragm and abdominal walls which accompany the increased respiratory movements forced on by the more rapid and more energetic contractions of the heart. The more powerful breathing leads to improved oxygenation of the blood and increased metabolism. All the organs in the abdominal cavity are favourably influenced by active walking; the appetite, the digestion, and assimilation are remarkably improved.

Thus walking exercises a favourable influence on the whole organism. We must therefore take daily walks and, if possible, in the open country, and do so in all weathers. The amount of walking required by different persons varies according to personal conditions and the manner of living; we may say between half an hour and two or three hours. It depends not only on the constitution of a person, but also to a great degree on the varying state of health and strength, on habit, on occupation, on the meteorological conditions—heat or cold, dryness or humidity, strong or light wind, or stagnation of air.

The walk ought not to be extended to actual fatigue, but ought to lead to exhilaration and agreeable warming of the whole body. The pace of walking, too, must vary in different persons, from less than a mile to three and four miles an hour, according to the condition of the walker and to habit, and ought not to be changed all at once from an accustomed slow to an unaccustomed very rapid pace.

With increasing age the power and the inclination to walk diminish, and this coincides with the diminution of the creation of warmth. Friar Roger Bacon, in the thirteenth century, stated that the body heat decreases after the age of 40. His statement agrees with the experience of many others as well as myself, though the exact age varies in different persons according to their general condition, their manner of living, and especially their activity. To prevent this decrease of heat production persons advancing in years must continue to walk or take other muscular exercises as much and as long as they can, and must not allow their friends to dissuade them from doing so, or yield to their own inclination to give it up. Even if it rains or snows, or the weather is otherwise disagreeable, they must continue to take their accustomed exercise; since, if they neglect it, and stay at home engaged in reading or some other occupation, they have great difficulty in resuming the necessary exercise. Great is in this respect the difference between the young and the old; the former can easily return to active muscular work after long rest, not so the latter. They must not regard their number of years but their physical capacity. If those advanced in years neglect muscular exercise their muscles waste, their metabolism fails, their body heat

diminishes, and their path to premature senile decrepitude is rapidly paved. On the other hand, it is to the majority of people almost incredible how much can be done by energy and will power to postpone this decay.

A matter which is not sufficiently considered is the mode of walking. A walk of three or four miles with half-bent knees and back is not as useful as one of the same length with firmly contracted muscles of the legs and thoroughly erect spine.

Persons with a sound circulation derive more benefit from walking uphill than from walking on level ground. Even to those with slight dilatation of the heart gentle ascents at a slow pace are very useful.

The benefit of walking is much enhanced by taking once or twice a week a longer walk in the country, and infinitely more so by walking tours of some weeks in mountainous or hilly regions. Marvellous is the improvement effected by them in the physical and mental condition. Old people need not be quite debarred from the benefit of such tours; they ought not to climb high mountains and glacier passes, but with judicious limits they can, with great benefit to themselves, do much more than is generally admitted.

Many other forms of muscular work can be advantageously substituted for walking, such as riding on horseback, hunting, shooting, cricket, football, golf, fishing, etc., some of which not only benefit the body, but also the mind and the character.

By walking we employ principally the muscles of the legs and the spine; we must also put into action those of the arms and the thorax. Those of the thorax we exercise through deep inspirations and expirations, which we effect by the contractions of the intercostal muscles and the diaphragm. In so doing we massage the ribs, expand the thorax and the lungs, keep up their elasticity, powerfully influence the contractions of the heart, and compress the organs in the abdominal cavity. By the massage of the ribs we keep them in a healthy condition, the bone substance as well as the marrow, with its blood-forming function.

With the respiratory movements we ought to combine exercises of the arms in various ways, extending them, for instance, vigorously with a deep inspiration, contracting them with a full expiration; raising them perpendicularly with deep inspirations, so as to allow the air to pass freely into the apices, which, with shallow breathing, are often insufficiently expanded, and are apt to become seats of disease. The habit of shallow breathing ought to be entirely avoided, and that of full breathing, which can and ought to be substituted for it, can and ought to be acquired by every one.

The effect of these arm gymnastics is, however, not restricted to the muscles of the arms alone, but extends to those brain centres which initiate their movements. As soon as they become active, an increased amount of blood rushes to them, the small blood vessels are forced to work, and the work keeps both the blood vessels and the brain substance in a healthy condition.

The muscles of the trunk we put into action by moving the trunk upwards and downwards with deep inspirations and full expirations; or by turning the body in the erect position as much as possible around its axis, with deep inspiration from the left side to the right, and with full expiration from the right to the left. There are many other methods of exercising the different sets of the muscles of the trunk.

All the muscular actions of the body have a certain action on the bones. Each contraction of a muscle causes a pull on the bone to which it is attached; this pull acts as a kind of massage on the periosteum, the bone substance, and the bone marrow. The nutrition of the different parts of the bones is through this process maintained; the well-known brittleness of the bones in old age is prevented, the bone marrow is kept healthy, and by improving the composition of the blood increases its power to combat hostile bacilli, and thus prevent disease.

After this short discussion of the muscular actions on different parts of the body, I venture to point out the following effects:

1. Increased afflux of blood to the muscle with each contraction.
2. Increased nutrition of the muscle, combined with improved metabolism and production of body heat.

3. Increase of exchange of fluid between blood and tissues.

4. Facilitation of the removal of waste products.

5. Preservation of the elasticity of the thorax and lungs.

6. Abundant supply of oxygen for the blood and the metabolism.

7. Maintenance of a healthy condition of the organs of circulation, from the heart to the smallest arteries, capillaries, and lymphatics.

8. Massage of the bones, keeping up the healthy condition of the bone substance and the bone marrow, and through this the formation of a sufficiency of blood efficient for the fight with hostile bacteria entering the blood.

9. Increase of the resisting power of the body against disease.

10. Persistence of the working capacity of the brain centres, which initiate the action of the different sets of muscles.

I add to this short paper a personal note regarding my view of the influence which muscular exercise has had on my longevity. I do this in the hope that some of my professional brethren may accept this view, and may induce their friends and patients to act on it in order to prolong their lives. I take no gloomy view of the conditions of old age, but think it a privilege to obtain a long life. It has not, I concede, all the pleasures, nor the powers—mental and physical—nor the imagination of youth; but it need not be helpless, useless, cheerless, and friendless if the aged person endeavours to be in harmony with the aims of the younger generations; and happily the mental faculties, especially intelligence, often survive the physical powers for many years, and enable the aged sometimes to give useful advice to his younger friends.

Although I know that it is not the exercise of the muscular system alone to which I owe the satisfactory condition of health and strength, which I retain in my 95th year, but that the attention to hygienic conditions in general, to the digestive functions, to the mental work, and the tenor of the mind, as I have explained in my little book on *Prolongation of Life*, has a great share in it, yet I am sure that the keeping up of the muscular system has played a prominent part in it, and does so still. The facts of my spending daily two to three hours in the open air, walking, as a rule, thirty, more frequently forty or fifty, miles a week and enjoying the beauties of nature, have not only an exhilarating effect on my mind, but keep up the whole organism and the resisting power to a considerable degree for my age. The possibility of heredity might be suggested, but this suggestion will probably be discarded, when I state that both my parents died in the 60th year—my father from cerebral apoplexy (a frequent cause of death amongst his forefathers), my mother from inherited weakness of the heart, leading to frequent bronchial attacks, anasarca and effusion into the pleural cavities. One might rather say that I had inherited a tendency not to long life, but to these life-shortening morbid conditions. If so I have been able to counteract them by energetic fighting against them from an early period of life.

THIGH STUMP EXTENSION SPLINT.

BY

WELBY E. FISHER, F.R.C.S.,

TEMPORARY ASSISTANT SURGEON TO ST. GEORGE'S HOSPITAL
SURGEON TO CITY OF LONDON MILITARY HOSPITAL.

The stumps following flapless or flush amputations of the thigh that have come under my notice after transport from the seat of war have all apparently suffered from having been unprovided during their treatment with some continuous extending force to counteract the natural tendency to retraction of the soft parts that in these cases leads to conical stump formation in a short time to a serious degree.

The nature of the injuries has necessitated, as a life-

saving device, the division of tissues without regard to adequate flap formation. But thereafter it becomes incumbent upon the surgeon to conserve for the patient every fraction of the stump possible. If the retraction of the soft tissues is permitted to proceed unrestrained until such time as secondary amputation is performed, it will be the general experience that an undue length of femur will require removal before the soft parts are capable of approximation, and that the ultimate shortening of the stump may prove very disappointing.

I am aware that stump extension is at times employed, but such contrivances as are usually made use of cannot, in my opinion, be relied upon to maintain the necessary continuous uniform traction during all movements of the stump and positions of the patient both in bed and during transport.

A splint that I have improvised achieves this, and after its use in numerous cases during the last two years I am able to speak of its utility. Unhappily, many of the cases that arrive in this country have reached a stage in which the tissues are fixed in retraction when counter-extension can obviously be of little use; this note is published in the hope that the splint may receive a trial in France to prevent retraction, and to afford the further advantages to the patient of freeing him from pain and of giving protection to the stump—all important factors during transport.

The splint is improvised from a Thomas splint, as modified by Jones for the arm; its ring will, as a rule, be found to slip comfortably over the thigh. One with a closely fitting ring having been selected, it is forcibly bent at the bars until the end meets the leather-covered ring, to which it is secured by a tape. A blow with a mallet will convert the ring to an oval that will, perhaps, better fit the contour of the thigh. In the rare event of the ring being too small, it may be enlarged by division with a saw close to the outer bar.

Improved thigh stump extension splint. Note: The aluminium ring is made large when indicated by the condition of the wound, and small when direct extension is required.

A length of about twenty inches of aluminium splinting is then bent in the form of a circle, loops within, and this hoop is then inserted and secured by tape or strapping between the ends of the bent bars of the Thomas splint, which are forced apart, if necessary, to receive it. The splint is now complete, and takes but a few minutes in the making.

Extension strapping is next applied to the whole length of the stump at the points of the circumference selected as best suited for effective flap extension. The projecting ends of the strips should be folded so that their adhesive surfaces are effaced, and in each two openings are snipped for the passage of tape that is so passed as, when extension is made, to appose the lateral edges of the plaster to the skin. The coaptation of the plaster strips to the surface is farther secured by a circular band of the same material round them all near the end of the stump. Efficient substitutes for adhesive strapping, and in some ways better, are strips of bandage or gauze affixed in like manner with glue.

The splint is now applied, the padded ring being carefully insinuated upwards until it gets a firm bearing against the tuberosity of the ischium. Being close fitting it gives additional security against slipping of the extension strips.

Extension is now made by drawing upon the tapes or strips and securing them by adequate tension in the direction of their application to their corresponding segment of the aluminium ring by slip-knots, daily attention to which will ensure that a uniform tension is maintained conforming with the give of the soft parts.

The splint is light, and forms a frame that supports and

moves with all movements of the stump, the flaps of which are held in fixed extension, while the splint is self-secured by means of its extension bands. Extension is maintained whatever the position of the stump and whatever its movement, so that the position of the patient can be varied and attendance on him rendered easy. After the application of the splint the patient is freed from pain, and no cradle is necessary, as the splint affords the necessary protection. The open aluminium ring allows access for swabbing and dressing, and from the side a kidney-shaped dish can be introduced beneath the wound.

The dressings being maintained in position by the framework of the splint, no bandage is required, so that access to the wound is ready and provides for prompt attention in case of haemorrhage.

I should like particularly to recommend the use of this splint during transport. The material is available and it requires only a few minutes to be made. In October, 1915, Sir G. H. Makins showed an adaptation of a Thomas knee splint, but not of the same character as mine.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

LONG LIFE AFTER EXCISION OF RECTAL CANCER.

It is well known that freedom from recurrence after complete removal of cancer of the intestine is more likely than in many other situations. As it is not always easy to obtain the history of a case after many years, I am much indebted to Sir William Whitla, of Belfast, for giving me the completed record of a case thirty-one years after operation. Such a case is of much interest, and affords encouragement. In 1887 I operated in Belfast upon one of Sir William's patients, assisted by Mr. (now Sir Anthony) Bowlby and Mr. Sinclair of the Belfast Royal Hospital.

The patient was a lady 53 years of age, who had had symptoms for six months. Examination under an anaesthetic showed that the disease commenced three inches above the anus, and extended upwards about four inches. It completely surrounded the bowel, producing considerable stricture. The posterior wall was more deeply invaded than the anterior. The operation was difficult and prolonged, but eventually, after freely opening the peritoneum, a complete segment of the bowel five inches in length was removed, including half an inch of sound margin both above and below the growth. Microscopic examination showed a typical specimen of adenoid cancer. The patient, under the care of Sir William Whitla and Mr. Sinclair, made a good recovery.

Five years later, owing to some contraction, an inguinal colotomy was performed (not under my advice). I saw the patient thirteen years after the operation. She was in excellent health, and there was no sign of recurrence. The colotomy opening gave hardly any trouble.

Sir William Whitla has most kindly sent me, under date February, 1918, a letter as to the sequence of the case: "I enclose a card informing you of the death of your old cancer case operated on in 1887. She has just died at the age of 84. Surely this is a record."

W. HARRISON CRIPPS,
Consulting Surgeon to St. Bartholomew's Hospital.

THE GUILLOTINE AMPUTATION.

THE number of cases in which a guillotine amputation has been performed at casualty clearing stations and base hospitals in France induces me to ask if some other method of amputating could not with safety be practised. Unfortunately I have not had an opportunity of seeing cases as they present themselves at a casualty clearing station, but I think it is equally unfortunate that so few surgeons working at the front have not had an opportunity of seeing the after-results of the guillotine method.

It may be that the fear of gas gangrene is the important factor which has caused this plan to be adopted so generally. A guillotine amputation invariably necessitates reamputation, but, apart from this, the great disadvantage is that by the time the patient arrives in England the skin has retracted so much that a large granulating and suppurating stump is exposed. The

dressings are often extremely painful, and the subsequent loss of bone, even after prolonged extension to draw the skin down, is sometimes very great.

May I suggest that in a fair proportion of cases flaps might be made and brought together by rubber button sutures, as advocated for reamputation by Major W. A. Chapple in the *BRITISH MEDICAL JOURNAL* of August 25th, 1917, p. 242? Ample provision for drainage is, of course, essential. I have adopted this plan in a number of reamputations with marked success, even in the presence of active suppuration.

I have been working at this hospital since August, 1914, and can recall distinctly the very unsatisfactory results obtained during the early part of the war, when amputations in France were performed in the orthodox way. At that time the flaps were made too close to the injured tissues, were stitched too closely, and adequate drainage not provided for. Now the pendulum has swung so far in the opposite direction that a few weeks after the operation, owing to skin retraction, the appearance of the stump would almost suggest that the patient had been amputated from the limb and not the limb from the patient.

If surgeons in France decide that after all it must be a guillotine amputation, I hope they will so modify it as to leave much more skin, and so dispense with many subsequent troubles, and save the ultimate length of the patient's limb.

I trust these remarks will be read in the spirit in which they are written, for I feel very proud of the excellent work being done by British surgeons at the casualty clearing stations in France, more especially in regard to abdominal injuries and wounds of joints. Why not bring amputations up to the same high level? The fact that we surgeons are all working for the same end—to learn what is true in order to do what is right—will, I trust, be a sufficient excuse for me venturing to criticize the work of others in a particular branch of surgery.

R. W. MURRAY, F.R.C.S.,
Major R.A.M.C.(T.).

Fazakerley, Liverpool.

SPONTANEOUS HAEMORRHAGE INTO THE PERITONEAL CAVITY IN ARTERIO- SCLEROSIS.

THE occurrence of spontaneous haemorrhage in cases of arterio-sclerosis with high blood tension is a matter of everyday experience, especially from the cerebral arteries. That such haemorrhages are not entirely confined to these arteries is also well recognized, as cases of severe epistaxis, metrorrhagia, haematemesis, and haematuria arise in the course of arterio-sclerosis. In the description of this disease in textbooks I have not found any mention of haemorrhages into the peritoneal cavity, and on this account report the following case.

Mr. T. M., aged 48, consulted me in March, 1912, complaining of transient loss of power over the lower limbs, headache, dizziness, and depression. He had hard and tortuous arteries, accentuation of second aortic sound of heart, and a blood pressure of 160 to 170 mm. In 1915 his symptoms had grown worse, and the blood pressure had increased to 180 to 190 mm. In July, 1915, he had left hemiplegia, from which he recovered. He also suffered from nasal polypi, and in September, as these were causing troublesome nasal obstruction, I removed them by snare. This operation was followed by severe haemorrhage, which was very difficult to control. In 1918 his condition was such that he found relief from his symptoms only by remaining in bed. On February 5th he remained in bed until the afternoon. He then got up, and, when taking some tea, was seized by a violent pain in the epigastrium. I saw him about an hour afterwards. He was then crying out with pain. His temperature was subnormal, and pulse 80. The abdomen was distended; the abdominal wall was rigid and board-like. There was dullness in both flanks, but no absence of liver dullness. I advised immediate operation.

Operation.—On opening the abdomen the upper part of the cavity was found full of blood. After swabbing this out I found a series of haemorrhagic patches scattered over the mesocolon, but failed to find any actual bleeding point. As his condition was very grave, and the haemorrhage had ceased, I closed the abdomen. Before doing so I examined the liver and the region of the pancreas, but could find nothing abnormal. There was no fat necrosis. He died six hours afterwards.

The interesting points of the case are:

1. The spontaneous nature of the haemorrhage without any history of trauma.
2. The close simulation of the symptoms to those following a ruptured viscus. The clinical picture presented at

the commencement of the haemorrhage was typical of perforated gastric ulcer.

J. W. HILLIARD, M.A., M.D.,
Honorary Surgeon, Victoria Hospital, Blackpool.

RESUSCITATION OF WOUNDED.

A good deal is now being done to resuscitate wounded men suffering from shock of wounds and exposure, with a result that is at once successful to the patient and encouraging to his medical officer. The transfusion of gun solution or blood has been so markedly successful in bringing round in a few minutes many wounded men who would otherwise have died, that it suggests the possibility of going a little further. My object is in no way to challenge the methods of resuscitation in use, methods which stand on the firm rock of results, but to deal rather with the soldier at a much earlier period, so as to have certain data in hand which might serve as a guide to the intelligent treatment of cases after the first shock of battle has been tided over. I refer to the taking of the specific gravity and viscosity of the blood of every recruit at some early stage—for instance, when the man is at the height of his training, in the best possible physical condition, and every function well and equally balanced. A true index might thus be found which, if put on his card, might help to regulate intelligent direction of treatment later on if necessary.

Present methods of treatment after operation appear to me to savour too much of groping in the dark. A bridle rein is required to guide us in our movements to the goal we would attain, and this communication is a plea that perhaps Nature has the guide ready to our hand. No two individuals have quite the same diathesis; every one has his own standard. Where in one the specific gravity may be 1 or zero as his normal necessary to perfect health, in another it may be *plus* or *minus* 1 as the case may be, and to raise the *minus* too much or to raise the *plus* insufficiently might just make all the difference.

While in charge of a V.A.D. hospital in England I, in a necessarily incomplete way, put this process into practice early last year, and took the viscosity and specific gravity of the blood of many wounded soldiers. Making the normal at zero, I found very few who came up to this standard or who agreed with each other. At the time I felt very much handicapped in not knowing the specific gravity and viscosity index of the individual in normal health, but even so I met with sufficient success to warrant considering the thing seriously. The taking of the specific gravity of every soldier would entail very little time, and could be done easily, quickly, and fairly accurately with mixtures of known specific gravity (ether, glycerin, etc.) in three or four bottles, and would require no more blood and much less time than is required in an ordinary blood count. Of course much more elaborate processes could be employed, and might be so later on in civil hospitals, but the above, I am sure, would be sufficiently accurate to meet the need, and would, I am convinced, be of immense assistance to the medical officer. By gradually raising the patient to his normal index and maintaining it at that by the use of gun solutions, or saline or other methods, his diathesis could more speedily be brought to an efficient degree, increasing his resistance to septic processes, and thus restoring him to health, and shortening the period of convalescence to that which now obtains. It is in view of the probably large influx into the army in the near future of men different and indifferent alike in physical qualities and standards of health that I with great diffidence send this communication.

ROBERT B. JOHNSTON, F.R.C.S., M.R.C.P.E.,
Lieutenant R.A.M.C.

BARCOO ROT (VELDT SORE).

IN the *JOURNAL* of June 9th, 1917, p. 761, Lieut.-Colonel C. J. Martin has made a very interesting addition to the pathology of barcoo rot, or veldt sore.

To those of us who have lived in tropical Africa any length of time the condition is well known, and is commonly referred to by the layman as "fever sore." Martin lays stress on the infection of the hair follicles being primary; with this I am inclined not completely to agree. I believe in many cases the initial lesion is a trauma through which the infection takes place, otherwise how is the distribution—backs of hands, extensor surfaces of

forearms and shins, that is to say those parts exposed to trauma—to be explained? Why are not other parts of the body, though admittedly generally less hairy, not affected? With an affected area the size of a three-penny piece on the back of the hand, naturally one or more hairs will be found passing through the lesion, and one would expect to find the follicles infected, but I am not convinced that this is primary. On the other hand, I do believe that hair follicles in the neighbourhood are secondarily infected by organism-containing discharges from the primary sore, just as happens in any pyogenic skin infection with the production of secondary lesions.

With Harman's view of the etiology, quoted by Martin, most of us will doubtless agree—namely, that the skin cocci are able to infect the epidermal structures of a man whose defences are weakened. The loss of resistance may be from many causes. The most marked case I have seen was in a European with symptoms of scurvy, but malaria, as is indicated by the local name, is often the predisposing cause. Want of cleanliness and attention I believe assist in the spread of the lesions, but not necessarily in the production of the initial lesion.

One other point. I am not convinced that similar infections do not take place in natives; the reason that they are not observed being that every skin lesion becomes immediately secondarily infected with pyogenic cocci, and its character thus changed.

With regard to treatment, I have had uniform success with a 20 grains to the ounce salicylic acid ointment after preliminary cleaning up of the ulcer and snipping away any overlying epidermis. Tropical practitioners will be, however, greatly indebted to Colonel Martin for pointing out the part the hairs play in delaying the healing, and in being responsible for the spread of the ulcer at its margins.

Reports of Societies.

TREATMENT OF TUBERCULOUS MESENTERIC GLANDS.

At a meeting of the Medical Society of London on February 11th, the President, Sir ST. CLAIR THOMSON, being in the chair, Mr. HERBERT CARSON, in a paper on the clinical aspects of tuberculous mesenteric glands, expressed the opinion that the resistance of the glands was lowered by septic invasion from the intestinal tract and subsequently infected with tuberculosis from the same source, the tubercle bacilli reaching the intestine in milk. He analysed a series of 50 cases submitted to operation, describing three stages—that is, simple enlargement, caseation, and calcification; 37 of the patients were below and 13 above 15 years; many patients had been ill for two or three years. In giving a description of a typical case he referred particularly to pain, which he considered diagnostic. It was a true colic, and due to (1) contraction of the circular muscular coat of the bowel. The condition had to be distinguished from chronic appendicitis, ureteric stone, digestive disorders, intestinal parasites, and lead poisoning. Complications were almost all of the type of intestinal obstruction. There were three cases of intussusception in the series, which Mr. Carson considered to be due directly to spasm of the affected segment of intestine. With regard to treatment, the necessity of correcting diseases of the nose, pharynx and mouth was emphasized and laparotomy advised even in typical apparently uncomplicated cases. Mr. Carson advocated removal of the glands rather than euretting in the uncomplicated cases. Where there was obstruction he advised the removal of the glands and the freeing of adhesions or enterectomy rather than short-circuiting or the formation of an artificial anus. The paper contained an analysis of the after-results in the 47 cases of recovery.

Dr. LEONARD GUTHRIE said that in his experience calcified tuberculous mesenteric glands were usually found only after death. They were very difficult or impossible to palpate. He thought colic was not sufficient for diagnosis. He was not accustomed to ask for operation for free fluid. Intussusception, of course, and obstruction

from whatever cause, must have surgical aid. In his own hospital the recoveries with medical treatment amounted to 80 per cent., and with surgical treatment to 50 per cent., the latter including surgical complications.

Mr. V. WARREN LOW thought that colic was not evidence of uncomplicated tuberculous mesenteric glands, but was definite evidence of obstruction of the intestine, due probably to a kink or adhesion. When he operated he usually left the glands alone, and prescribed rest, small doses of tuberculin, and open air. A large proportion of cases got well. He had always found the colic associated with a rise of temperature which was out of proportion to the clinical symptoms. He had not regarded tuberculous mesenteric glands as a clinical entity.

Dr. WALTER CARR thought it impossible for tuberculosis of the glands to go on to calcification without fever. Were tuberculous mesenteric glands found in every case in which the typical symptoms occurred? Calcareous glands were often found in the abdomen *post mortem*; they did not usually give rise to tuberculous peritonitis, this being caused by (1) blood infection and (2) local extension of infection from the intestine. Tuberculous mesenteric glands might give rise to miliary tuberculosis. In London the bronchial glands were more often the source of infection, whereas in Scotland the infection appeared, as a rule, to come from mesenteric glands.

Mr. H. J. GAUVAIN agreed that tuberculous mesenteric glands existed without tuberculosis elsewhere. Of 2,000 cases of the bones and joints the mesenteric glands were affected in some. He had never come across the colic described by Mr. Carson as typical of these cases. He did not operate to remove the glands. The treatment he used was open air, and, when the glands were getting smaller, he endeavoured to assist calcification by administering calcium salts.

Dr. EDMUND CAUTLEY thought that the symptoms described were not evidence of tuberculous mesenteric glands. He considered that many of Mr. Carson's cases were not instances of purely tuberculous mesenteric glands, for there were complications which showed extension to the peritoneum. Operation was not profitable unless there was a complication indicating the necessity for it.

Mr. CARSON, in reply, said that he regarded colic as a constant symptom, and without it a diagnosis of tuberculous mesenteric glands should not be made. The children he had described were all on the down grade, getting thinner and more ill. In his experience pain was not usually associated with the complications.

SYPHILIS AND STILLBIRTHS.

At a pathological meeting of the Liverpool Medical Institution on February 14th, Mr. W. THELWALL THOMAS, President, in the chair, Professor J. M. BEATTIE read a note on the examination of 409 stillbirths for evidence of syphilis. Spirochaetes were found in the organs (liver, spleen) in 49. The blood of 35 fetuses showed a positive reaction in 26 and a negative in 9. Related to these 9, the mothers showed the following results: 4 were positive, 4 were indecisive, and one was negative. Absence of spirochaetes was noted in one fetus, in which, however (and in the mother), the blood test was positive. The negative result of the blood test in 9 fetuses was ascribed by Professor Beattie to probable bacterial infection of a saprophytic nature, interfering with haemolysis. His conclusion was that the prevalence of syphilis in regard to stillbirths was 15 per cent., and his results corroborated those of other observers. He considered it most desirable, in the absence of other obvious causes of stillbirths, that the blood should be examined with the object of ascertaining the presence or absence of syphilis. Dr. BRIGGS, professor of midwifery and gynaecology, agreed with the findings of Professor Beattie and said that the clinical evidence supported them.

VOGEL of Breslau has found that though the total incidence of venereal disease in the German army was comparatively low (about 0.3 per cent.), syphilis, as compared with gonorrhoea, had become more common. The incidence ratio of syphilis to gonorrhoea, which was as 1 to 3 or 4, had risen to 1 to 2. Another disquieting fact was the high proportion of married men—a third of the total—among infected soldiers.

Rebichus.

BRITAIN'S HERITAGE OF SCIENCE.

WE welcome the appearance of *Britain's Heritage of Science*,¹ by Professor SCHUSTER and Dr. SHIPLEY, for the public has remained too long in ignorance of the commanding part played by the British in extending the boundaries of scientific knowledge. Until within recent years little or no attempt has been made to elevate the great record of scientific achievement in this country to the dignity of history; politics, the church, and the law have been investigated from every point of view by the historians, but the wider and more important field of science has been left uncultivated. To this is due an abyss of ignorance concerning the most fundamental scientific facts which largely govern the world at the present time. For this the men of science must be held in large measure to blame. Knowing the grand heritage of science in this country handed down by their ancestors, they have rarely troubled to give the glowing story to their fellow men. They have not considered it necessary to devote their powers to the task of describing, so that all may understand, the value of the scientific efforts of men who were often intellectual giants.

But this book does much to remove the reproach, and here we have unfolded by experts a comprehensive account of the activities of science in this country. The authors have successfully piloted their narrative between the style of the *Popular Science Educator* and that of the writer of scientific matter, which is too often technical and cumbersome. Any man of ordinary intelligence can, and should, understand this book, and we make bold to say that after reading it he will be amazed at the great scientific results obtained by his countrymen. So far as we know, this is the first attempt to give a comprehensive view of the history of British science in all its branches by men who occupy the position of authorities, and we congratulate them on the success of their efforts.

Having said so much, we may advance some criticisms concerning the plan and scope of the work. For the account given of scientific endeavour and its results, coming as it does first hand from experts of known ability, we have nothing but high praise and thanks to them for having conferred upon us a great benefit. More than any other branch of writing, the history of science can adequately be dealt with only by the expert, and it is no easy matter to present the subject, as the authors have, in such a form that the fundamental principles of historical writing are not violated. In this book it could not be expected that the whole history of science in these isles could be dealt with in the space of some 300 pages without considerable condensation, and we think, in the attempt to mention the names and work of so many who during the last 300 years have advanced science, the book has become overloaded.

The biographical matter contained in the volume is scanty, and no doubt the requirements of space have forbidden the attempt to give anything like full biographical details. But what is given is in such bare outline that we are constrained to believe that the book would have gained had the biographies been almost entirely eliminated. By far the larger part of the volume is devoted to a consideration of physical science, and this part may be described as a masterly review of that subject. The accounts given of the work of Newton, Cavendish, and Clerk-Maxwell are particularly competent, and, with this example before us, we could wish that Dr. Schuster would devote himself to writing a complete history of physical science, where he would be emancipated from the cramping influences of consideration of space. Such a book, we feel sure, would take rank with Whewell's *History of the Inductive Sciences*.

The last hundred pages of the book deal with biological science, and it was almost inevitable that the account would suffer from compression. With the chapters on botany and geology we have no complaint, nor with that on zoology, which contains an admirable review of Darwin's work. We think, however, that scarcely full justice has been done to the work of John Hunter, and

that mention might have been made of the work of Edward Tyson.

In the chapter devoted to the history of physiology the attempt has been made to combine accounts of physiology, medicine, and pathology, and the result has not been altogether successful. Even had the history of physiology alone been attempted, a short chapter of twelve pages would scarcely have sufficed to give even a bare outline of the work accomplished by British physiologists. Many omissions occur; not a word is said about the work of Matthew Baillie, of Richard Bright, and of William Prout, while others receive only a passing word. If Sydenham, whose great work was mainly clinical, finds a place, surely the same honour should be accorded to Heberden, Willan, Sir Thomas Watson, and others. In another edition this chapter might well be remodelled, not only in the direction of amplification but also in arrangement, for it gives the impression of having been thrown together rather loosely. We should also have welcomed a chapter on anatomy, for this country possesses a great heritage in that subject, and the work of Douglas, Parsons, Monro, the Hunters, Baillie, and Wilson, together with many of their successors, should receive due recognition.

But these points do not greatly mar the general excellence of the book, and we again thank the authors for having described the effort of Great Britain in such a way that all may know the part our countrymen have played in the realm of science.

TREATMENT OF CEREBRO-SPINAL MENINGITIS.

PROFESSOR DOPFER, in his book on the diagnosis and treatment of cerebro-spinal meningitis,² gives, in a preliminary description of the clinical aspects, an account of the latent cases and of the manifestations in old people, who show little fever and very well marked contractions. In some anomalous cases the cerebro-spinal fluid is clear, and contains a predominance of lymphocytes (76 to 80 per cent.); but if the patient survives, the ordinary polymorphonuclear predominance soon follows. After considering the diagnosis from meningism, the distinction from other forms of meningitis is shown to depend on bacteriological examination. How entirely up to date this work is may be gathered by the reference to the occurrence of meningitis due to infection by the *Spirochaeta icterohaemorrhagiae* without jaundice. Clinically cerebro-spinal fever may be confused with typhus, but in meningococci infection the purpuric rash appears on the first or second day, whereas in typhus it is not seen before the fourth day of the disease. The laboratory tests are fully dealt with, and illustrated by figures.

The subcutaneous and intravenous injections of serum Dopfer considers useless. He recommends washing out the subarachnoid space with normal saline before the injection of serum. The injection of serum into the cerebral ventricles is described both in infants and in adults after trephining. The beneficial effects of antimeningococci serum are insisted upon, and its failure from factors such as insufficient treatment, meningitic adhesions, blocking of the communications between the subarachnoid space and the cerebral ventricles, and the presence of Dopfer's parameningococcus, is discussed. Serum disease is not more frequent after intrathecal than after hypodermic injection of serum. The occurrence of meningeal symptoms due to serum treatment is described and explained. This handy volume gives an excellent account of the diagnosis and treatment in a short space.

HEWLETT'S "PATHOLOGY."

THE fourth edition of Professor HEWLETT'S book, *Pathology, General and Special, for Students of Medicine*,³ maintains the general standard of excellence of the preceding editions. The text has been subjected to revision and several of the old sections have been expanded and new matter particularly in connexion with the war, has been added, as, for instance, on trench foot, trench fever, trench nephritis, toxic jaundice of munition makers, gas gangrene, and gassing.

Without wishing to be hypercritical, we would have

¹ *Diagnostic et traitement de la méningite cérébro-spinale*. By Dr. Dopfer, médecin principal de 2^e classe, professeur à l'École du Val-de-Grâce, 1918. Paris: J. B. Baillière et fils. 1918. (Cr. 8vo, pp. 96; 17 figures. Fr. 2.)

² *Pathology, General and Special, for Students of Medicine*. By R. Tanner Hewlett, M.D., F.R.C.P., D.P.H. Fourth edition. London: J. and A. Churchill. 1917. (3vo, pp. 631; 37 plates, 15 figures. 12s. 6d.)

³ *Britain's Heritage of Science*. By A. Schuster, F.R.S., and A. E. Shipley, F.R.S. London: Constable and Co. 1917. (Cr. 8vo, pp. xv + 334; 15 portraits. 8s. 6d. net.)

liked to see a rather more generous treatment of the subject of pigmented moles or melanomas with a brief account of their structure; and some reference to the more modern views on the subject of chronic endometritis, to the haemolytic forms of jaundice, and, perhaps, a modification of the phrase on p. 428, "Recent work has shown that haematogenous jaundice probably does not exist." This work can no longer be classed as "recent." Further, on p. 582, under the section on tumours of the brain, aneurysm seems out of place. A word or two on the occurrence of aneurysms of the branches of the circle of Willis might well have been added, especially in view of the frequency with which they occur and of the possibility of leakage tinging the cerebro-spinal fluid, which is so often examined nowadays.

The book is illustrated by thirty-seven plates and fifteen figures. Some of the plates with figures of microscopical sections might be better. They are reproduced in very much too dark a tone, so that the detail is obscured.

The book remains an admirable one for students of medicine; it is concise and clear and contains a sufficient summary of the various theories concerning some of the more complex phenomena to form a sound basis on which to build further study.

NOTES ON BOOKS.

DORLAND'S well-known *Medical Dictionary*,⁴ first published in 1900, has now reached its ninth edition, and contains more than 2,000 new terms, mainly due to the war, and over 40 pages more than before. There is such an extraordinary amount of information contained in this encyclopaedic dictionary that it is impossible to imagine any brain that could carry all the details given on the various subjects. The lists of diseases, tests, syndromes, operations, and methods supply the answer, sometimes hard to obtain, as to what So-and-so's disease or test is. Most readers agree that the use of the describer's name in the nomenclature of disease is generally undesirable, but as it appears that the habit cannot be suppressed entirely, it is well to have an unfailing source of reference. It has often been said that on the whole it is just as useful to know where to find a piece of information as to have it at the tip of the tongue, and those who share this belief will find Dorland's dictionary, with its illustrations, an invaluable source of reference.

⁴ *The American Illustrated Medical Dictionary*. By W. A. Newman Dorland, A.M., M.D., F.A.C.S. Ninth edition, revised and enlarged. Philadelphia and London: W. B. Saunders Co. 1917. (Pp. 1179; 317 illustrations, of which 115 are coloured. 21s.)

HOSPITAL FOR LIMBLESS MEN, CARDIFF.

THE Prince of Wales Hospital at Cardiff for men who have lost limbs, opened by the Prince on February 20th, is designed to meet the needs of sailors and soldiers who have lost limbs in this war, but it is intended to be a permanent institution for the benefit also of men crippled by accidents in agriculture or other industry. It is the gift of citizens of Cardiff to Wales and Monmouthshire.

The movement for its establishment was initiated by Colonel Lynn Thomas, C.B., C.M.G., who, from his experience as one of the consultant staff of the Roehampton Hospital for limbless men, had become impressed with the need for establishing corresponding institutions in each part of the country. His proposal was supported by the then Lord Mayor, Dr. R. J. Smith, and before any public appeal was made funds were found for the initial expenditure by two Cardiff merchants, Mr. J. P. Cadogan and Mr. W. Percy Miles. A large house which had been the Mansion House of Cardiff was purchased in September, 1916. It had a garden and outbuilding. Beyond the garden were two other smaller houses, and both of these were purchased; the one has been converted into an officers' block containing 12 beds, and the other into a home for the female staff. The main building provides accommodation for 53 men, and a ward with the necessary attached offices has been reserved on the ground floor for those who have lost both legs. In October, 1916, Commander Lord Tredegar, R.N.V.R., presented the freehold of the whole property.

The house is entered by an inclined plane, and another leads into the garden. On the open ground between the main building and the quarters for the officers and staff, workshops for the making of artificial limbs, a parade hall, and billiard rooms for officers and men have been estab-

lished. Experience having shown that it is very necessary in such an institution to have arrangements for testing artificial limbs in actual use, special provisions have been made in the parade hall and in the garden. The aim has been to enlist the man's interest and co-operation all through. When a man first wears his permanent artificial leg he is taken to the parade hall, a long room with terrazzo floor and two sets of parallel bars to suit men of different heights; he makes his first steps resting his hands on the bars and walks towards a mirror, in which he can see for himself any error he may make in his first attempts, and is shown by an instructor how to correct it. An artificial limb cannot be considered perfectly adjusted until it is of exactly the right length, and of this the man himself is the best judge. Sometimes, however, he finds difficulty in judging; this is overcome by a very simple expedient. The parade hall is provided with long, loose narrow boards varying in thickness from an inch to a quarter of an inch; the man tries walking with his artificial limb on one board after another until he finds the board which exactly suits him. The leg is then elongated by the thickness of the board.

The garden has been laid out with taste and skill, so that in his next stage the man can get accustomed to variations in the pitch of roads and paths, which pass almost unnoticed by a man with two sound legs. This "miniature Wild Wales" has rough stone paths, some on the level and others presenting gradients varying in pitch up to 1 in 3½; moreover, the paths are laid so that as the man walks his right foot is in one stretch higher than the left, and in another the left higher than the right.

For a man who has lost both lower limbs the difficulty of learning to walk is very great; in order to get into the artificial apparatus he has had to depend on two people to lift and steady him, and it was not easy for him to gain confidence. This difficulty has been overcome by a special appliance, an "aërial-transporter crutch," consisting of pulleys and tackle, by which a man can lift himself from his wheeled chair into his artificial limbs and allow so much of his weight to rest upon them as he feels he can bear.

The training of men in the use of artificial arms is superintended by an armless collier, himself the inventor of an ingenious worker's arm (the Welsh arm) which he has used successfully for over twenty years. In the garden there are pits for the men to practise shovelling, and the use of the pick, axes and saws, and wheelbarrows. In addition to outdoor work there are shops for steel workers, carpenters, glass-blowers, and leather workers, which are carried on under the supervision of the Cardiff Technical College.

The artificial limbs are made on the spot, so that it is easy to carry out minor adjustments, and no man is discharged until he pronounces his limb comfortable. The workshops are provided with apparatus for testing the breaking strain of steel wires, thongs, and ropes used in the construction of limbs, and provision is made also for experimenting with new inventions and designs for artificial limbs for the upper and lower extremity.

The new hospital serves during the war as a special annexe of the Orthopaedic Centre, Welsh Metropolitan War Hospital, Whitechurch, to which the wounded are admitted either direct from a convoy or after a period in a general hospital. At Whitechurch the patient undergoes such surgical treatment, including operation, as may be necessary, and when he has reached a suitable stage of recovery is fitted with a temporary appliance called a "pilon," first used, we believe, by Belgian surgeons. It is a modification of the old-fashioned peg-leg the bucket being made of plaster-of-Paris bandages. With this temporary appliance he is encouraged to get about, and as soon as possible is sent to an auxiliary hospital at the seaside (Penarth). When he has made suitable progress he is admitted to the Prince of Wales Hospital and provided with an artificial limb and passed through the scheme of training. In a similar manner men who have lost an arm are first admitted to a Red Cross hospital at St. Pierre, Cardiff, with a temporary appliance, and are later sent to the Prince of Wales Hospital. Officers who have lost a limb go during the time for which they are wearing the temporary appliance to another Red Cross hospital in Cardiff. By this arrangement the beds in the Prince of Wales Hospital are kept free for patients who are being actually fitted with a permanent limb.

British Medical Journal.

SATURDAY, FEBRUARY 23RD, 1918.

FORMS AND REFORMS.

SIR WATSON CHEYNE, in his speech on the address at the opening of the new session of Parliament on February 12th, expressed an apprehension that the moral of the country was in danger of being lowered by the growth of the belief that things which tend to interfere with the earnest prosecution of the war were not being put down with a strong hand; that there was too much yielding to expediency; that there was undue delay in making decisions, and in taking action when decisions were made; that parochial instead of wide views were allowed to prevail; that underhand intrigue, whether in favour of an individual or a section of the community, was not put down with a firm hand; and that incompetence was condoned, and in some cases seemingly rewarded. Sir Watson Cheyne was no doubt speaking quite generally, though the two illustrations he gave referred to medical matters. They both related to delays; in the one case the delay in the publication of the report of the Committee sent to France to inquire into matters connected with the personnel and administration of the medical services in that country, and in the other the delay in the establishment of the Air Medical Service. He did not explain his hint that "incompetence is condoned and in some cases seemingly rewarded," and he may not have been thinking specially of the medical services, but some appointments made in those services cannot but make the judicious grieve.

A fortnight ago we gave some particulars of the extent of the Home Commands, and of the importance of the duties with which the Deputy Directors of Medical Services in these commands were entrusted, instancing as one, and the chief example, the control and inspection of the very large number of military hospitals of various grades, and of the different special institutions which exist in each command. There are officers holding these appointments who, to speak for once quite bluntly, have not given evidence that they possess the knowledge, ability, or adaptability qualifying them to discharge the duties of the offices they occupy; it is, indeed, alleged that the recommendations of competent advisers have been misunderstood, ignored, or obstructed. We shall be glad to be assured that, in making appointments to these influential posts, merit, competence, and mental elasticity to adapt itself to the new conditions have alone been taken into account, and that senior officers have not been appointed merely because, in peace, it has been the habit to appoint senior officers to these posts, and because there were no other posts of lesser responsibility vacant. We should very much regret to think that Sir Watson Cheyne's statement, that in the army "incompetence is condoned and in some cases seemingly rewarded," applied to the medical service.

Leaving out the Aldershot Command and the London District, which are special cases, the whole of Great Britain is divided into five commands. There

are about 88,130 square miles in Great Britain, so that if it were equally divided there would be about 17,620 square miles in each command; scattered over each of these areas there are a very large number of hospitals, it may be as many as four hundred, many military institutions for the treatment of special conditions, and also convalescent camps, command dépôts, and other medical units. But Great Britain is an island of very irregular form, and the areas of the commands are not symmetrical geometrical figures. The Western Command, for instance, is an acute angled triangle with its apex at the Solway and its base at the Bristol Channel, a distance in a straight line of about 240 miles. The map of Scotland, or of the Northern or Southern Command, reveals very similar geographical configuration. If we suppose the principal medical officers of the various commands energetic men, possessed of wide and varied clinical knowledge, so that they could quickly judge the efficiency of the treatment given, having experience in the management of a busy hospital (which an army medical officer trained in peace may never have entered since he was a student), and if finally we suppose them endowed by a fairy god-mother with seven leagued boots, then possibly their administration might be efficient.

We understand that recently the number of Assistant Directors of Medical Services has been increased, in the hope that they might help the Deputy Directors of Medical Services in the commands, especially, we gather, in the inspection of hospitals. There is, we fear, much room to doubt whether these new appointments for senior regular medical officers are likely to produce the desired result. Some at least of these officers appear to suffer from the delusion (which they take no pains to conceal) that anybody can operate, but that it takes a very clever fellow to administer. They do not, however, seem to be proving the proposition in their own persons. There is evidently a risk, at least, that they may attach undue importance to outward forms and be more concerned, for instance, in the correctness of the patient's costume than in the rightness of his treatment. They, or some of them, have succeeded in conveying the impression that in home administration they are still governed by what is said to be the watchword of some of their fellow officers abroad, "Evacuate! evacuate!" Whether this watchword can be applied abroad except by men of good judgement and sound clinical instinct is a matter which may be open to discussion, but, whatever its value with an army in the field, it cannot be transferred directly to hospitals at home, where quite different criterions as to the length of time a man should be retained for surgical or other treatment apply.

The matter of records may be taken as a concrete example of the strange inability of some principal medical officers to understand a new idea. We explained last week the simplified and improved system worked out at the request of the War Office by the statisticians of the Medical Research Committee charged with the compilation and analysis of army medical statistics, and pointed out the many advantages of a uniform system. It might have been supposed that any man of the world possessing business ability would have rejoiced at the change. But the Deputy Directors of Medical Services, or some of them, had not the gumption to take care that the change was made—that orders were obeyed. The result is that in some hospitals, if not in all, the new system has been superimposed on the old, and the two sets of forms, the old and the new, are still required to be made out, no doubt

"in own handwriting." Such a result may seem beyond belief, but some who have had experience of army ways, especially at home, seem to find it quite easy to believe. We are told that not all authorities are equally zealous in the collection of autographs, but their assiduity is irritating enough everywhere. We know of one military hospital where the signatures of orderly medical officers are collected at the rate of 4,000 a day. On a rough calculation the signatures for a year, if arranged in a row, would extend from London to Aldershot or thereabouts. We know of another hospital, not so large, where the number of returns required to be furnished by the officer in charge alone to head quarters averages sixty-three a week. Is any one so simple as to suppose that head quarters reads them? Then in this, as in every other military hospital as at present administered at home, there are all the reports and notes of all the medical officers of all the wards and divisions, and all the diet sheets to be noted daily, the handwriting of no one but the medical officer being permitted to appear, and all the proceedings of boards, and so on, and so on. As was stated last week, we have been informed that there is no army regulation requiring reports of boards to be furnished in triplicate and in autograph. But, though there was no regulation justifying it, the requirement was enforced. Who is to blame for this irregularity entailing so great a waste of medical man power at a time when there is a great shortage of it? Until better informed, we can only reply—the Deputy Directors of Medical Services in the Home Commands, whose business it is to see that instructions are carried out and not exceeded. They are nothing if not administrators, but in this, as in not a few other respects, they seem to have failed as administrators.

The Army Medical Service started this war with a great asset in the goodwill of the civil profession and the confidence inspired by the knowledge that Sir Alfred Keogh, who had planned the Territorial medical organization, would be in charge to watch over its application from the chair which he is about to vacate. The civil profession, through the British Medical Association and other civil professional bodies, had striven hard for the autonomy of the Army Medical Service and to ensure that it should be provided with adequate means and authority for carrying on its duty to the army. It was rewarded by the smoothness with which the plans to meet such an emergency as that of the autumn of 1914 worked, by the success of the schemes for the prevention of epidemic diseases in the armies, and, above all, by the spirit of comradeship and enthusiasm in which the new problems in the treatment of the wounded and sick were speedily tackled and steadily investigated until one by one each has been solved or brought nearer solution, with ever-increasing improvement in results and untellable diminution of suffering and permanent incapacity.

In the articles published in recent issues we have endeavoured to deal with defects which the long continuance of the war and the great accumulations of the wounded, disabled and sick have disclosed, especially at home. We have sought to do so with frankness but with every consideration for individuals. We know that some reforms have been and are being introduced, but we are convinced that many others are necessary and that the demand for their application is becoming irresistible. We believe that the Army Medical Service still has an opportunity of initiating and carrying through these reforms if it will act promptly without fear or favour.

CRANIO-CEREBRAL WOUNDS.

OPINION as to the principles and practice of cranio-cerebral surgery in advanced formations in the field has undergone considerable modification in the past three years. Upon military grounds some still hold that penetrating wounds of the skull demand more time and skill, than can be justified by results, in periods of heavy fighting, arguing that the "walking wounded" and those likely to return to the firing line, should, by preference, receive attention from the most experienced operators. On the other hand, it has been the aim of the medical services, when possible, to save every man who can be rescued by promptitude and skill, whatever his prospects as a combatant for the future; hence the admirable advanced operating centres for "head," "abdominal," "chest," and "femur" wounds established within easy reach of the fighting front. Notwithstanding wide divergence of view in some directions, there is almost unanimous agreement among medical men of all armies, allied and enemy alike, that early operation is imperative, and that all cases not actually moribund should be afforded such additional chances of recovery as operation offers.

The special centres set up in our own armies have done admirable work, not only directly, by saving individual lives, but also, encouraged, supported, and guided by the higher authorities, indirectly, by affording opportunities for regular weekly discussions amongst the medical officers, and for the systematization of records. It was of happy augury for surgery when the friendly arrangements between the medical corps of the British and United States armies led to an American officer with an international reputation in operative neurology being posted to one of these centres. Professor Harvey Cushing brought to a strange field and new conditions a great experience and a finished technique; he was provided with a complete equipment and a trained team of assistants. In his first weeks of work he ascertained that the existing rate of operative mortality was very much the same as that in all other similar centres—namely, 50 per cent. He frankly faced the hard fact that his own earliest results were not quite so good; sought the reasons; discarded whatever in his accustomed methods seemed unsuitable, and adopted novel ones, justifying his departures from his own past practice by a steady reduction of mortality from 55 per cent., in three months, to 29. It was a remarkable achievement, and we can well believe that to watch the evolution of his practice in those three months was a lesson not thrown away upon the centre, especially the operators, and that it has had an effect upon their own results.

Professor Cushing, whose preliminary communication we publish this week, would be the first to admit that while he taught, he also learnt, and that the particular routine and technique he personally employs and now describes, as indeed he expressly states, is not the only one capable of producing results similar to his own. He starts from the ground common to all workers in the field of war wounds: "infection" is the bugbear. All clinical experience points that way; autopsies, such as the consecutive series carried out at the same group centre, particularly by Captain W. Briggs, clinch the argument. The essence of Cushing's as of other successful schemes for the elimination of infection, is a simple but invariable routine carried out with minute attention to details from the earliest moment.

It is, perhaps, worth insistence on some of his chief details. He begins at the field ambulance, with the

suggestion that every "head" case should have a first dressing of spirit soap; this facilitates shaving very materially, and the razor is one of the best "antiseptics" for the skin. He advises local anaesthesia in preference to inhalation, although formerly he was a convinced adherent of the latter mode. His method of removing the damaged area of bone *en bloc*, though it needs suitable instruments, is simple, easy, and purposeful. The finger, that most delicate of probes, is, he says, too clumsy for the brain. Replace it, then, by a very soft catheter, which, employed as he directs, is at once an exploring antenna and an almost perfect means for cleansing a brain track of the detritus which is an already-inseminated culture medium. Then follows the removal of all accessible foreign bodies: bone, by suction, or by delicate forceps after localization, favoured oftentimes by aid from the conscious patient who coughs to order; metal, by the magnet when feasible.

With a wound, then, as clean and dry and free from extraneous matter as possible, but almost surely not free from organisms, is it practicable to inhibit the growth of bacteria, at any rate until the natural defensive forces have rallied? In the use of dichloramine-T, dissolved in oils, Professor Cushing thinks he has found a means for continuous antibacterial action without harm even to the cerebral tissues, and, so far as his clinical series constitutes an experiment, the evidence is in his favour.

After the primary operation all cases should be dressed in the theatre under like conditions—re-cleansing of the track, lumbar punctures, secondary operations if needed, secondary sutures, all should take place as part of the daily routine under the surgeon's own eye, if not always by his own hand. The time spent is amply repaid, and the system has another great advantage, that it ensures completion of the neurological records begun at the moment of admission. It is mainly because the triradiate incision leaves the track more accessible to inspection and cleansing at the dressings that he prefers it to the flap. It was a rule of these centres, before Professor Cushing arrived, that every case must be retained until the danger of post-operative complications was certainly passed—that is, for the best part of a month or longer—so that when he speaks of his cases as having "passed the stage of conceivable complications" before evacuation, he is clearly not referring to late symptoms such as those occurring in the remarkable case we publish to-day, where Captain Rayner and Captain Barclay effected great improvement, both psychological and physiological, by the late extraction of a small foreign body, using an ingenious instrument of their own device.

One of the trials of operators at a "head" centre dealing with cases of which hitherto one in two have died in their hands, is the uncertainty as to how much value in the community those whom they save will eventually have. Are they but preserving their lives to leave them a burden to their friends and to the state? There is a certain amount of information in our own recent literature¹ and a considerable body in continental journals—for access to which we have to thank the unobtrusive and necessarily imperfectly acknowledged but fully appreciated labours of the Medical Research Committee—altogether an accumulation of evidence that late complications are neither so numerous nor so serious as was formerly believed.

It is to the perfecting of early operations and to the refinement of practice in the immediate and remote

after-treatment we must look for the abolition of damaging sequelae. Thanks to Cushing, thanks also to the initial contributions of Gray, Sargent, and many another British surgeon, not to mention our continental brethren, we are on the road to the goal.

MEDICAL STUDENTS IN THE RANKS.

A NEW Army Council Instruction, No. 153 of 1918, has been issued with regard to the release of medical students serving with the colours for the purpose of resuming their professional studies. A medical student now serving with the colours who at the time of his enlistment was engaged in medical studies, and who (a) is in his third year, or (b) at the time of enlistment had passed the whole of the professional examination in chemistry, physics, and biology (or botany and zoology) for a medical degree or licence, is, if eligible and he so desires, to be transferred (regardless of his medical category) to Class W or W(T) of the Reserve, or discharged if ineligible for transfer to the Reserve, for the purpose of resuming his studies with a view to obtaining a medical qualification. A third year student is defined as one who had on or before enlistment completed two years of medical study, and who can within thirty-six months complete his professional curriculum and obtain his medical degree or licence. A medical student desiring to be released from the colours under this Instruction must apply through the usual channels, stating the date on which he wishes to be released, and undertaking to resume his studies with a view to qualifying. Presumably the application should be made in the first instance to the company officer in the case of a soldier, and to the commanding officer when the applicant holds a commission. If a third year medical student, he will be required to produce a certificate from the dean of his medical school (or the official corresponding to the dean), showing (1) whether he has or has not passed his professional examination in anatomy and physiology; (2) that prior to enlistment he had satisfactorily pursued his professional studies during two years, and was then actively studying with a view to qualification; and (3) that he can qualify within thirty-six months. If not a third-year student, he must produce a certificate from his dean showing that prior to enlistment he had passed the whole of the first professional examination, and that at or immediately before enlistment he was actively pursuing medical studies and had been studying as a whole-time medical student for at least six months at a recognized medical school or college. In each case the student will add to the certificate the address of the medical school at which, and the date on which, he is going to resume study. General Officers Commanding at home and abroad are directed to issue the necessary orders for bringing the provisions of this instruction before the notice of the medical students concerned, and to obtain from officers commanding units the names of men who have produced the certificate mentioned above, and who desire to be released. The further procedure is also given in detail. In the case of medical students serving in the ranks the approving authority for their release will be the General Officer Commanding, but where a medical student who comes within the terms of the Instruction is holding a commission a statement of his case, together with the necessary certificates, is to be forwarded by the General Officer Commanding to the Army Council for its consideration and decision. Any student transferred to the Reserve must forthwith resume his medical studies and enrol in an officers' training corps, under penalty of being recalled to the colours. At intervals not exceeding six months he must forward to the officer in charge of records a certificate from his dean stating that he is satisfactorily pursuing his studies and making reasonable progress therein, together with a certificate (except in the case of students coming under A.C.I. 1196 of 1917) from the commanding officer of

¹ Vide, for example, BRITISH MEDICAL JOURNAL, January 5th, 1918, p. 29.

his officers' training corps, stating that he has made himself efficient during the preceding six months. A.C.I. 1196 of 1917 applies only to medical students who have held combatant commissions, and have been returned to their professional studies. These, if not given honorary rank, must undertake and carry out all the ordinary officers' training corps obligations of medical students.

SURGICAL SHOCK.

It will be remembered that at the end of February, 1917, the Medical Research Committee issued a memorandum on surgical shock and some allied conditions, which we published in full on March 24th, 1917. In August, 1917, the Committee appointed a Special Investigation Committee to co-ordinate inquiries into surgical shock and allied conditions, with a view to the correlation of laboratory and clinical observations. It consisted of Professors E. H. Starling (chairman), F. A. Bainbridge, W. M. Bayliss, W. B. Cannon, M.D. (Harvard, Captain M.O.R.C., U.S.A.), A. N. Richards, Ph.D. (University of Pennsylvania), C. S. Sherrington, Surgeon-General Cuthbert Wallace, Colonel T. R. Elliott, Captain John Fraser, R.A.M.C. (of Edinburgh), with Dr. H. H. Dale as secretary. The Medical Research Committee has now received three reports through the Investigation Committee, and these have been printed for official distribution; but as they are of an interim nature they will not be placed on sale until the investigation has proceeded further, when it is hoped that a volume may be issued for sale. The first report, on intravenous injections to replace blood, by Professor Bayliss, brings down to a later date (November 25th, 1917) the results of his researches as detailed by himself in the *JOURNAL* of April 28th, 1917, p. 564, and in his paper to the Royal Society, a note upon which was published in this *JOURNAL* on December 8th, 1917, p. 772. The third report (January 7th, 1918), by Captains Hamilton Drummond and E. S. Taylor, R.A.M.C.(I.), discusses the use of intravenous injections of gum acacia in surgical shock. They used clinically the solution mentioned in the February memorandum of the Medical Research Committee, with the addition of gum; the formula is, sodium chloride 2 grams, potassium chloride and calcium chloride, of each 0.05 gram, powdered gum acacia 5 grams, distilled water 100 c.cm. The solution was made in a mobile laboratory by Major J. W. McNee, and, to remove all particles, was filtered through paper pulp under pressure before being autoclaved. More recently it has been found convenient to make up a solution of five times this strength, and to dilute with sterile water as required. No untoward effects were observed, and at necropsies on cases which succumbed from their wounds after transfusion no pathological lesions dependent on the fluid introduced (thrombosis, etc.) were met with. The fluid must be introduced very slowly, allowing fifteen to twenty minutes for each pint injected. The transfusion has been carried out with the ordinary apparatus used for injection of saline, the solution being kept at 118° F., and a pint being the amount usually given at one time. The best results were obtained in haemorrhage attended by little shock; fair results were met with in haemorrhage with shock of moderate severity; little improvement was obtained in cases of advanced shock dependent on severe damage to hollow viscera. The great importance, in wounds of the extremities, of arresting all possible sources of haemorrhage before transfusion is pointed out; otherwise as the blood pressure rises haemorrhage may at once begin again and leave the patient worse off than before. In some severely lacerated limbs it was found best simply to apply a tourniquet before the transfusion was begun and to deal with the bleeding points at the subsequent operation. In cases of intra-abdominal haemorrhage the practice has been to start the transfusion at the beginning of the operation, losing no time in finding the sources of the bleeding immediately the abdomen is opened. The

second report is the joint production of Captains Cannon, E. M. Cowell, J. Fraser, and A. N. Hooper. It consists of a series of papers on blood pressure in wound conditions, on alterations in the distribution and character of the blood, on acidosis, and on the initiation, nature, and preventive treatment of wound shock, with which we cannot at present deal.

ACTION OF ALCOHOL.

An Advisory Committee was appointed in November, 1916, by the Central Control Board (Liquor Traffic) to consider the conditions affecting the physiological action of alcohol, more particularly the effects on health and industrial efficiency produced by the consumption of beverages of various alcoholic strengths. It consisted of Sir George Newman (Vice-Chairman), Professors Cushny and Sherrington, Dr. F. W. Mott, Dr. H. H. Dale, Mr. W. McDougall (Reader in Mental Philosophy, Oxford), Captain M. Greenwood (Reader in Medical Statistics in the University of London), and Dr. W. C. Sullivan (Medical Superintendent of the Rampton State Asylum for Criminal Lunatics), with a lay chairman. Its report, with a preface by its lay chairman, Lord D'Abernon, has now been issued in a slim volume, entitled, *Alcohol: its Action on the Human Organism*.¹ It is a very balanced document, and will not altogether please the advocates of total abstinence, inasmuch as it shows that some of their habitual statements are exaggerated. At the same time, it does not give the believer in the extraordinary merits of alcoholic beverages any ground to rejoice. The most it can say in his favour is that the temperate consumption of alcoholic liquors, in accordance with certain rules of practice, may be considered to be physiologically harmless in the case of the large majority of normal adults, and that this conclusion is fully borne out by the massive experience of mankind in wine-drinking and beer-drinking countries. But it adds that it is true that alcoholic beverages are in no way necessary for healthy life, that they are harmful or dangerous if the precautions advised are not observed, and that they are definitely injurious for children and for most persons of unstable nervous system, notably for those who have had severe injuries of the head, or who have suffered from attacks of mental disorder or from nervous shock. The Committee points out that the main action of alcohol, apart from the effects of its continued excessive use, is confined to the nervous system, that it is narcotic rather than stimulant in action, that its nutritional value is strictly limited, and that its habitual use as an aid to work is physiologically unsound. On the vexed question of the formation of the alcohol habit and the existence of craving the Committee expresses the opinion that the person who is in the habit of taking alcohol takes it primarily for the sake of the agreeable effects produced through the nervous system, because he finds that it relieves the sensations of fatigue, and because he believes that it gives him increased energy for his work. It is held that while the return or persistence of these motives undoubtedly contributes to the regular use of alcohol it differs from such habit-forming drugs as opium and morphine in the fact that its sudden withdrawal causes less severe symptoms and that no high degree of tolerance is acquired by its prolonged use, but it is pointed out that these are differences in degree rather than kind. In regard to the common use of alcoholic beverages in moderate quantities, such as the habit of many people to take wine or beer with meals, the Committee expresses what we conceive to be the sound view—namely, that these beverages are taken because to the majority the taste and immediate effects are agreeable, and that the pleasure derived therefrom outweighs their estimate of remoter harm, if any thought be given to such ulterior considerations. "To the abstainer either the taste or the immediate effects are not agreeable, or the

¹ London: H.M. Stationery Office. Price 2s. 6d. net; 2s. 10d. post free, or through any bookseller.

remoter ill, whether real or imaginary, seems more important. Each class manufactures arguments in favour of its own line of conduct." The report does not deal with the social evils or moral problems which result from the excessive use of alcoholic liquors, but solely with the physiological aspects of the alcohol question. The precautions the report recommends are that the ordinary use of alcohol should not only be moderate but that it should be taken at intervals of time sufficient to prevent the persistent presence of a deleterious amount of the drug in the body, and that to avoid direct injury to the mucous membrane of the stomach alcohol should not be taken in concentrated form and without food. There are two or three useful appendices; one of these shows what we have found it difficult to come by—namely, the amount of proof spirit and of absolute alcohol in the usual retail measures of the ordinary alcoholic beverages. The report is a very guarded statement, but as an impartial presentment of the case will be found extremely useful and informing.

COMPULSORY RATIONING.

THE rest of Great Britain has not had to wait long for the extension of the Meat Rationing Order, which comes into force for London and Home Counties on Monday next. In a number of other districts committees already have in force registration or rationing schemes for meat which have had the effect of abolishing or diminishing queues, and the committees in districts where meat queues are still prevalent are being urged to adopt temporary registration schemes before the compulsory scheme comes into force on March 25th. In France the order to which we have already referred also comes into force on Monday next. It forbids the manufacture of fancy breads, and requires that flour used for the manufacture of bread shall consist of whole flour with or without certain authorized additions. The weight of bread to be allowed will eventually be regulated in accordance with the occupation of the consumer. The order forbids altogether the manufacture or sale of pastry, or fancy biscuits, or sweetmeats prepared with sugar or honey, or with milk or cream; or ices made with milk (fresh or condensed), cream, eggs, sugar or flour. In hotels, restaurants, clubs, buffets, and tearooms, butter, milk, cream, or cheese may not be supplied, and at a hotel, restaurant, or club, when the charge for a meal is more than 6 francs, two dishes only, with a modicum of bread, soup, and a *hors d'œuvre* or oysters may be served, but dessert may be taken provided that it contains nothing made with cream, milk, sugar, eggs, or flour. No grain suitable for human food may be used for the manufacture of alcohol, nor given to any animal. The use of chocolate for making sweetmeats will be stopped after March 2nd, and on that date regulations will come into force as to the sale of gluten bread and similar products. The seller must have a licence, and every package must bear his name, and particulars as to the composition of the special bread.

AN OLD EXPERIMENT IN RATIONING.

IN these times of short supplies it is right to profit by the experience of our ancestors, but, in drawing conclusions, it is as well to be sure we know what that experience was. These reflections were prompted by hearing the remark that the famous case of the Millbank penitentiary established the importance of a meat ration for prisoners. The Millbank experience is, indeed, highly instructive, but, as we shall proceed to prove, the lesson to be learnt is not quite that deduced by our interlocutor. We suppose that the, perhaps, not very large number of medical men who have even heard of the Millbank case derive their knowledge of it (possibly not at first hand) from a little treatise published in 1825 by Dr. P. Mere Latham, physician to St. Bartholomew's Hospital, under the title, *An Account of the Disease Lately Prevalent at the General Penitentiary*.

In this work Dr. Latham sets forth how in July, 1822, the penitentiary diet underwent a change which "reduced the animal part of the diet almost to nothing." In lieu of solid meat, the prisoners were given soup made of pease or barley in which ox heads were boiled in the proportion of one ox head to 100 male prisoners. Latham estimated that this allowed an ounce and a quarter of meat to each person. By the late autumn the "general health of the prisoners began visibly to decline. They became pale and languid, and thin and feeble. Those employed in tasks requiring much bodily exertion were unequal to the same quantity of work as formerly. Those at the mill could grind less corn; those at the pump could raise less water. From time to time several of the laundry women fainted under their work; and the business of the laundry could only be carried on by continually changing the hands engaged in it." By February both scurvy and dysentery had a grip of the prisoners. The scurvy was soon checked when the diet was improved, fresh meat and oranges being given, but the dysentery was not to be denied, and in the end "the only measure which remained was to set at liberty all the female prisoners, without exception, for the sake of preserving their lives." The bulk of Latham's work is devoted to a careful and extremely interesting study of the clinical features of the epidemic of dysentery, and the casual reader might certainly infer that the only change at Millbank in 1822 was the reduction of meat; hence the natural inference that fresh meat must be given. But Latham, writing so near the event, did not think it necessary to enter into details which he might reasonably assume to be familiar to his readers. Even in 1823:

Non obtusa adeo gestamus pectora Poeni,

at any rate to the extent of ignoring altogether the sufferings of these malefactors, particularly when urged by the verdict of a coroner's jury to the effect that one of them was starved to death. A Select Committee of the House of Commons reported on the incident. The report is a voluminous document; many pages are devoted to the question of whether the prison doctor had or had not on a certain night drunk too much wine; others record the badgering to which the temerarious deputy coroner and his jury were subjected; while on the slightest provocation, or without provocation, members of the committee or witnesses delivered speeches the phrasing of which would turn a modern parliamentarian green with envy. But amid all this verbiage is embedded useful physiological information. Meat was not the only article of diet reduced. In addition to giving the ox-head soup instead of 24 oz. of cooked beef, without bone (6 oz. four times a week), a daily allowance of 1 lb. of boiled potatoes was cut off and nothing given in exchange; less gruel was also provided. The result, so nearly as we can calculate, was that a diet providing 116 grams of protein and 3,498 calories was replaced by one yielding 86 grams of protein and only 2,644 calories. Further, the only vegetables regularly supplied were celery, carrots, turnips, and parsnips, with potatoes now and then, in the proportion of 1 lb. to five persons, added to the soup, and probably kept at near the boiling point for some hours. Again, the heating of the prison was extremely defective, it being in evidence that during the winter the temperature of many cells did not rise above 46° F. We see that the mere energy content of the diet was utterly insufficient for anything but sedentary work, while the deprivation of potatoes and the exiguous supplies of other vegetables courted an outbreak of scurvy. Hence this grim experiment does not establish the necessity for meat in the diet, but is instructive in other ways. We have a sequence of events which may be regarded as pathognomonic of the effects of food shortage. First, a gradual failure of energy, then, accelerated by exposure to cold, surrender to the most accessible infectious disease, which here happened to be

dysentery—whether dysentery had been present in the gael before the change of diet, formed the topic of an animated controversy between Latham and the chairman of the committee, of which we hold Latham to have had the better. It is also to be noted that, when the mischief had been done, improving the diet did not suffice to limit the disease. Colonel Hehir, in his account of the Kut-el-Amara disaster (third appendix to the Report of the Mesopotamia Commission), records similar observations. Among other points of interest in the Select Committee's report are dietaries of marines and seamen, of prisoners of war in 1797, and of convicts on passage to Botany Bay. The seamen received, we reckon, 4,083 calories, allowing nothing for a daily gallon of beer; the prisoners of war had 1,898 calories—which explains some incidents in Stevenson's *St. Ives*—while the Botany Bay convicts received 2,362 calories on their journey.

ANTITYPHOID LIPO-VACCINE.

THE method of preparing an antityphoid vaccine, about which Mr. Lynch recently questioned Mr. Macpherson in the House of Commons, was described in 1916 by Le Moignie and Pinoy to the Biological Society of Paris, and is spoken of as lipo-vaccine T.A.B. Le Moignie, or Le Moignie-Pinoy, by Tribondeau,¹ principal medical officer of the French navy, who investigated the serological reactions of 150 new entries vaccinated therewith on June 13th, 1917, at Toulon. The cases were followed for thirty-seven days, and showed that after the sixth day agglutinins for typhoid and paratyphoid A and B bacilli appeared in all without exception, the reaction being better marked in the case of typhoid than of paratyphoid B, and of paratyphoid B than of A. After the expiration of a month from the injection some of the serums no longer agglutinated, and on the thirty-seventh day half of the cases failed to agglutinate. As shown by the complement deviation test, the fixation antibodies appear rather later than the agglutinins and disappear about the same time. The activity and multivalency of the vaccine are thus promising, and if its protective powers in man are proved to be as satisfactory as Tribondeau anticipates, its use would have the advantage that one injection only, instead of two to four, as in the case of aqueous antityphoid vaccines, would be necessary; the toxic effects, such as fever and local reaction, it is stated, are very slight. The dose is 1 c.cm. containing seven thousand million of typhoid and paratyphoid A and B bacilli, mixed in equal parts in oil. The experiments of Gautrelet show that toxins and poisons when mixed with oil for the most part lose the power of affecting the nervous system, which they possess when in aqueous solution, and this is quoted by Tribondeau to explain the absence of reactions after the lipo-vaccines.

Medical Notes in Parliament.

Army Medical Promotions.

MR. LLEWELYN WILLIAMS asked Mr. Macpherson, on February 18th, whether he was aware that discontent had been caused in the Army Medical Service by the late list of promotions to the higher ranks of that service, colonels and surgeon-generals, as a result of which a large number of officers, some of whom possessed distinguished records for professional work, had been passed over for promotion; whether these promotions were the result of consideration of the qualifications of the officers by an impartial and formally constituted board of senior officers; and if so, what was the constitution of that board; if such a board were constituted, what instructions were given to it to guide it in making its selection; and, alternatively, if no such board were constituted, on what system was the selection made, and had due attention been paid to scientific and professional qualifications, as apart from purely administrative ability.

Mr. Macpherson replied that the recent promotions were made in some instances among officers who perform purely

professional duties, and in others both professional and administrative capacity were duly considered. The promotions were made specially for the purposes of the war, and officers not so selected are still eligible for promotion in the ordinary course. The recommendations of general officers commanding were obtained and carefully considered, and the selections were made by the Adjutant-General, in consultation with the Director-General, Army Medical Service, after exhaustive inquiry, and were finally submitted to the Secretary of State for approval.

Army Dental Service.—In answer to Mr. Pennefather Mr. Macpherson stated that dental surgeons were available in cases of doubt, and frequently carried out inspections where a special opinion was required as to the condition of the teeth of men joining the service. Inspecting dental officers had been employed in commands at home since December, 1915. They carried out their duties under the instructions of deputy or assistant directors of medical services, who were responsible to general officers commanding for the physical fitness of all soldiers. Subject to such general instructions, inspecting dental officers naturally acted on their own instructions. There was no army order forbidding the transfer of dental surgeons with combatant and other commissions to the dental service; but so long as dental surgeons were available for commissions from the ranks it had not been the practice to transfer commissioned officers. Four motor dental ambulances were in active operation at the front—all in France. Five such ambulances had been offered and accepted, none had been refused; four had been delivered, and, so far as he was aware, were in use. The fifth ambulance had not yet been received.

THE WAR.

TETANUS IN HOME MILITARY HOSPITALS: AN ANALYSIS OF 1,000 CASES.

IN the JOURNAL of October 23rd, 1915, Surgeon-General Sir David Bruce published an analysis of cases of tetanus treated in home military hospitals during the first year of the war, and summaries of four further analyses have appeared in these columns. At a meeting of the Society of Tropical Medicine and Hygiene on October 19th, 1917, he took as the subject of his presidential address an analysis of 1,000 cases of tetanus,¹ in which he brought together the results already published, together with the latest figures which had not hitherto appeared. This comprehensive report follows the lines with which our readers are already familiar, but, in reviewing the figures as a whole, Sir David Bruce discusses certain points at greater length. An attempt was made to amalgamate the cases of tetanus arising in England with those which occurred in France before transfer, but, through lack of sufficient data, this was found to be impracticable. Judging from the information available, the proportion of wounded men attacked by tetanus in home military hospitals may be roughly put down as 1 per 1,000. This, however, is not the true incidence of tetanus among the wounded in this war. The wounded in France and the wounded in England are not distinct and separate populations, for the wounded in England were at one time the wounded in France. Probably about 800 cases have occurred overseas. These, added to the English cases, would give the true incidence if every wounded man came over from France, but many return to duty without being evacuated to England. It is therefore not possible at present to give the true incidence for this war, but, roughly, it may be put down as about 2 per 1,000.

The working definitions of general and localized tetanus given in previous analyses are repeated. Among the thousand cases it was found that 896 could be placed in the general and 99 in the local group; in 5 it was doubtful to which group they belonged. Trismus was recorded in 607 cases. In each succeeding analysis the proportion of cases of local tetanus became larger; this may be set down to the introduction of prophylactic injection, and also in a less degree to the greater number of localized cases being diagnosed as tetanus.

The incubation period is again carefully studied. Analysis of the whole number of cases confirms the law already laid down that the shorter the period of incubation the higher the rate of mortality. The remarkable lengthening out of the period of incubation which has taken place during the war has changed the whole picture of tetanus from being an acute disease

¹ L. Tribondeau: *Compt. rend. Soc. Biol., Paris*, 1917, lxxx, 782-3; and *Arch. méd. et pharm. nav.*, Paris, 1917, civ, 276-282.

¹ *Transactions of the Society of Tropical Medicine and Hygiene*, November, 1917.

almost always fatal to a chronic disease with a case mortality of some 20 per cent. This result may fairly be taken as a measure of the action of prophylactic inoculation of antitoxin.

Of the thousand cases, 594 recovered, giving a mortality rate of 40.6 per cent. This rate is, however, too low, since it does not take into consideration the cases which occurred in France, and which were naturally of a more severe type than those occurring in England. Including the figures for France analysed by Sir William Leishman and Major Smallman, the total mortality in 1,339 cases comes to about 50 per cent. The death-rate in pre-serum days was about 85 per cent. Sir Charles Bell, in his diary, written after the battle of Waterloo, describing a case of severe tetanus, wrote: "There are but two cases living of all that had this affection." The lowering of the death-rate from 85 to 50 per cent. is doubtless due in great part to the introduction of prophylactic inoculation, and it must be borne in mind that during the first months of the war, so far as prophylaxis was concerned, we were still practically in the pre-serum days. The progressive fall in the rate of mortality during the war was well shown in a table printed in a summary of the last analysis in the *JOURNAL* of December 1st, 1917. In the first year it was approximately 58 per cent., and has since then steadily fallen to 19 per cent. in 1917. Whatever may be the cause, or causes this result is highly satisfactory.

Among his negative findings, Sir David Bruce states that the figures furnish no evidence of any seasonal prevalence of tetanus. Nor do wounds of the trunk seem to be followed more often by fatal tetanus than wounds of the limbs—in fact, it is rather the other way. Again, from the full figures no case can be made out either for or against the intrathecal route for therapeutic injections of antitoxin, and no useful deduction can be drawn as to the influence of dosage on the curative action of antitetanic serum.

While it is clearly of the greatest importance to arrive at a true estimate of the curative value of antitoxin, the difficulties are at present insurmountable. Thus the greatest variety is found in the mildness or gravity of the cases; complications are frequent and often very severe; while the method of treatment varies according to the predilections of the different medical officers. With so many factors coming into play it is unwise to dogmatize from the figures available, but it should be noted that among the 40 cases not treated with antitetanic serum after the onset of symptoms, 32 died, giving a mortality of 80 per cent., against a mortality of 38.8 per cent. among the 960 so treated.

Summing up the position as it now appears, Sir David Bruce writes:

Antitoxin has no power of neutralizing toxin fixed in the nervous system. If a fatal amount has been absorbed, then no amount of antitoxin will save the man's life. If there is any free toxin circulating in the blood or lymph the antitoxin can neutralize it, and so possibly prevent further mischief. If, then, a fatal amount has not been absorbed the injection of antitoxin may be of use. By animal experiment it is proved that the intrathecal route is the best. It is believed that the intravenous route is also good, but more dangerous on account of the liability to anaphylactic shock.

While the incidence of tetanus among protected and unprotected soldiers respectively cannot at present be determined, through the absence of the necessary data, there is very strong presumptive evidence that prophylactic inoculations lower the incidence of tetanus among the wounded. A diagram of the ratio of the number of cases of tetanus to the number of wounded shows the great drop in November, 1914. No doubt there were several factors at work, but almost beyond question the introduction of prophylactic injections of antitetanic serum at that time was the preponderating cause. It was not until about the middle of October that prophylaxis was introduced on anything like an adequate scale, and it was precisely at this time that the remarkable fall in the incidence took place. From about mid October the supply of serum became equal to the demand, and thenceforward its use became practically universal. But beyond this the figures show conclusively that prophylactic injection lengthens in a marked degree the incubation period, and, as has been stated many times, the longer the incubation period the lower the death-rate. Among the thousand cases, almost one half certainly received a prophylactic injection. Of

these 363 recovered, giving a mortality of 26.6 per cent. Of the 239 cases who almost certainly had no prophylactic dose of any kind 100 recovered, giving a mortality of 58.1 per cent.

As to the value of multiple injections, the evidence is at present scanty, for it is not long since the Tetanus Committee laid down that four prophylactic injections should be given to every wounded soldier at intervals of seven days. The figures, such as they are, seem to justify the Committee in making the rule, since the incubation period tends to lengthen as the number of inoculations increases, and the case mortality to fall. "All that can be said is that there is justification for going on with the experiment until more evidence is accumulated."

Sir David Bruce's efforts to elucidate the problems of causation and cure have been greatly aided by the voluntary labours of Lady Bruce, who, at vast expense of time, entered up the items of information under the various headings, giving to this work an average of some five hours a day during the past three years.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Killed in Action.

SURGEON PROBATIONER D. J. WHITTON, R.N.V.R.

Surgeon Probationer David John Whitton, R.N.V.R., was killed in action on February 11th, aged 21. He was the only son of Mr. William Whitton, and was educated at Kirkcaldy High School and at Edinburgh University, where he was a third-year medical student when he joined the navy in August, 1917.

Died on Service.

STAFF SURGEON G. R. MILL, R.N.V.R.

Staff Surgeon George Robertson Mill, R.N.V.R., died on service on February 11th, aged 37. He was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1901, and M.D. in 1905. He afterwards acted as senior house-surgeon of the Royal Southern Hospital, Liverpool, and then went into practice at Birkenhead, where he held appointments successively as honorary anaesthetist to the Liverpool Dental Hospital, honorary medical officer of Birkenhead Maternity Hospital, and honorary assistant medical officer of Birkenhead Borough Hospital. He was a member of the Liverpool Medical Institution, and Secretary of the Birkenhead Medical Society. On April 8th, 1909, he joined the Mersey Division of the Royal Naval Volunteer Reserve as surgeon, and was promoted to staff surgeon last year. In the early part of the war he served on the hospital ship *Rewa*, which was recently torpedoed in the Bristol Channel.

ARMY.

Killed in Action.

CAPTAIN G. S. ELLIOTT, M.C., A.A.M.C.

Captain George Stephenson Elliott, whose death we announced in our issue of October 27th, 1917, aged 32, was born at West Charlton, Victoria, Australia, the son of the late Thomas Elliott of Ballarat and brother of General H. G. Elliott, C.M.G., D.S.O., of the A.I.F. He was educated at Ballarat College, where he distinguished himself in both study and sport. On deciding to study medicine, he entered Ormond College, Melbourne University, where he continued his distinguished career. He was winner of the 100 yards University Championship and was awarded his blue for athletics and football. He also played for Victoria in the interstate football contests. He graduated M.B., B.S. in 1915 and shortly afterwards left for overseas. After a few months' work in a field ambulance, he was posted to a battalion and remained there until he met his death at Polygon Wood. He was awarded the Military Cross for his services while R.M.O. Few officers enjoyed greater popularity, and his death has cut short a brilliant career. He leaves a widow and one child.

DEATHS AMONG SONS OF MEDICAL MEN.

Cameron, Percy Grant, Lieutenant Royal Garrison Artillery, attached Royal Flying Corps, youngest son of the late Dr. John Cameron, of Lochgilphead, Argyllshire, reported missing August 19th, 1917, now presumed killed on that date, aged 25.

Mackenzie, Ronald Patrick, Captain Royal Scots Fusiliers, elder son of the late Dr. Alexander Flyter Mackenzie, of Glasgow, reported missing on April 19th, 1917, now presumed killed on that date. He attained the rank of captain on June 1st, 1916.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SUPPLEMENT to the *London Gazette*, issued on February 18th, contains a further list of rewards for gallantry and distinguished service in the field. The acts of gallantry for which the decorations are conferred will be announced subsequently in the *London Gazette*. The following awards are made to medical officers:

Second Bar to Military Cross.

Temporary Captain A. Fullerton, R.A.M.C. (M.C. gazetted January 1st, 1917, and bar to M.C. October 18th, 1917).

Bar to Military Cross.

Captains W. Fotheringham, R.A.M.C.(S.R.) (M.C. gazetted August 16th, 1917), F. W. Lees, C.A.M.C. (M.C. gazetted January 1st, 1917), T. A. Townsend, R.A.M.C. (M.C. gazetted November 25th, 1916).

Temporary Captain W. J. Knight, R.A.M.C. (M.C. gazetted May 31st, 1916).

Military Cross.

Captains F. Chadwick, R.A.M.C., G. M. Foster, C.A.M.C., A. McL. Ferrie, R.A.M.C.(S.R.), A. S. Porter, C.A.M.C., R. D. Moore, R.A.M.C., J. G. Morgan, R.A.M.C., G. Young, R.A.M.C.(S.R.).

Temporary Captains E. P. Blasbki, R.A.M.C., T. M. Crawford, R.A.M.C., W. C. Douglass, R.A.M.C., J. H. Legge, R.A.M.C., J. O. Thomas, R.A.M.C., P. H. Wells, R.A.M.C., E. W. G. Young, R.A.M.C.

Temporary Lieutenant F. B. Elwood, R.A.M.C.

Fourth Class Assistant Surgeon J. G. Goodman, I.S.M.D.

Third Class Subassistant Surgeon Ata Muhammad Khan, I.S.M.D., has been awarded the Indian Order of Merit of the Second Class.

Dr. Grace Eleanor Soltan has received the King's permission to wear the Insignia of the Third Class of the Order of St. Sava, conferred upon her by the King of Serbia in recognition of her services to the Serbian sick and wounded under the auspices of the Scottish Women's Hospitals for Foreign Service.

NOTES.

BRITISH RED CROSS AND ORDER OF ST. JOHN.

THE third annual report of the joint finance committee of the British Red Cross Society and the Order of St. John of Jerusalem has just been issued, covering the year ended October 20th, 1917, and including a statement of accounts for the past three years. The administration and management of the great work of the Red Cross at home and abroad during the twelve months under review involved no direct charge upon the funds subscribed by the public for the benefit of the sick and wounded. The income of the Red Cross, however, showed for the first time since the war began a deficiency as compared with the expenditure.

THE "ELSIE INGLIS" HOSPITAL UNIT.

On February 18th the King and Queen inspected in the grounds of Buckingham Palace the "Elsie Inglis" Unit of the Scottish Women's Hospitals, the plans for which had been made in broad outline by Dr. Inglis in the few days immediately preceding her death. The unit and the Jugoslav Division, to which it was attached, were evacuated from Russia in November, 1917, and it was Dr. Inglis's wish that when the division took up work on another front, as it has already done, the hospital unit should rejoin it. The members of the unit assembled in the grounds of the palace, and the six executive officers were presented to Their Majesties. Dr. Inglis's successor in the chief medical officership is Dr. Annette Benson, and the assistant medical officers are Dr. Lilian Chesney and Dr. Gladys Ward. After the inspection, the King paid a tribute to the work performed by the Scottish Women's Hospitals, and wished the unit success in its further labours abroad.

AUTOMOBILE LABORATORY WITH WORKING ANNEXE.

Mr. Henry S. Wellcome, founder of the Wellcome Bureau of Scientific Research, has recently presented to the War Office for the use of the Army Medical Service an automobile bacteriological laboratory, very completely fitted up. A special feature is an annexe which, when the laboratory is halted, can be quickly set up and the apparatus arranged in it. This annexe and the bacteriological fittings are ingeniously designed so that they can be readily assembled and securely packed on the three ton chassis.

INCREASED WAR OFFICE CAPITATION GRANT TO CIVIL HOSPITALS.

In October last the British Hospitals Association held a conference to discuss the need of an increase in the War Office capitation grant for the maintenance of sick and wounded soldiers in civil established hospitals. Four weeks later a deputation waited upon the Financial Secretary to the War Office. This led to the formation of a joint committee of the British Hospitals Association and of the War Office, which visited representative hospitals in various parts of the country and drew up a report. An Army Council Instruction (No. 144 of 1918) has now been issued authorizing an increase of the maximum daily grant from 4s. to 4s. 9d. for each soldier patient under treatment, as from October 1st, 1917. From the same date a grant of 6d. per diem for each unoccupied bed, held at the disposal of the military authorities by their desire, is also sanctioned.

England and Wales.

MANCHESTER AND DISTRICT RADIUM INSTITUTE.

THE report presented to the annual meeting of the Manchester and District Radium Institute on February 15th, when the Lord Mayor was in the chair, stated that during the last year 588 persons had applied for treatment, an increase of 86 over 1916. Seventy were found to be not suitable for treatment, while of those treated 73 were well at the end of the year, 208 had improved, 74 had not improved, 22 had died of the disease, and it was too early to form any judgement of 128. Excluding cases of rodent ulcer, 36 cases of malignant disease (which is about 9 per cent.) were rendered free of signs and symptoms, and 24 cases of rodent ulcer and 13 of non-malignant disease were apparently cured. In the first year of the institute out of 519 cases treated only 45 were reported as well at the end of the year. These figures are significant as showing that with the later and improved methods a far greater proportion of the cases were successfully treated. From the financial statement presented by Sir William Milligan it appeared that the institute had a total credit balance of £1,320, and in addition had £5,000 invested in War Loan. Some discussion arose as to the purchase of a further quantity of radium, Dr. Burrows, the radiologist, pointing to the increased number of persons applying for treatment, and the need for a certain amount for laboratory use.

MILK FOR CHILDREN AND MOTHERS.

The Milk (Mothers and Children) Order, 1918 (dated February 8th, 1918), issued by the Food Controller, acting under the Defence of the Realm Regulations, empowers any local authority within the meaning of the Notification of Births Act, 1907, to arrange for the supply of food and milk for expectant mothers and nursing mothers, and of milk for children under five years of age, and prescribes the conditions under which this power is to be exercised. The quantities of food and milk to be supplied must not in any case exceed the amount certified to be necessary by the M.O.H. or the M.O. of a maternity or child welfare centre working in co-operation with the local authority, or by a person authorized by either of these medical officers, or by some other person appointed by the local authority for this purpose. If one of these duly authorized persons certifies that the provision of food or milk is necessary, food or milk may, in necessitous cases, be supplied free or may be sold at less than cost price. The expression "milk" is to include any preparation of milk prescribed by the M.O.H. or the M.O. of a maternity or child welfare centre working in co-operation with the local authority. A local authority may combine for the purpose of carrying out the order with another local authority or any local food control committee. Power is

reserved to the Local Government Board to require an authority to put the order in force or to combine with other authorities. The medical officers of health may be trusted to see that the milk is good and clean, and in this connexion we may note an interesting address given by Dr. Stenhouse Williams, of University College, Reading, research bacteriologist in dairying, Board of Agriculture, to a recent meeting of the Liverpool Medical Institution. He described the results of experiments concerning the keeping properties of clean and dirty milk under varying conditions. He thought that with attention to, and the inculcation of, hygienic cleanliness from the beginning to the end of milk handling the problem of clean milk would be solved and an enormous amount of spoilt milk saved for the benefit of the community. An appalling number of gallons of milk were, he said, wasted annually through improper and wasteful methods of handling and distribution. For a remedy he looked rather to education of the dairy community in correct methods, than to legislature, especially when it was brought home to the milk producers that clean milk was financially within their reach and as easily obtainable as dirty milk.

A STATE MEDICAL SERVICE UNDER A MINISTRY OF HEALTH.

We have received from Dr. Sidney Barwise, County Medical Officer of Derbyshire, a copy of a leaflet entitled "A Ministry of Health and a State Medical Service," setting out the changes which, in his opinion, should be made in public health administration. With regard to central administration, he considers that the health powers of the Board of Education, Home Office, Board of Trade, and Central Midwives Board should gradually be vested in the Local Government Board, whose president would become the Minister of Health. The Insurance Commissioners' duties should remain as at present, except that medical research work and the supervision of the medical treatment of insured persons should be transferred to the Ministry of Health. As far as local administration is concerned, on the preventive side, the most urgent matter, in Dr. Barwise's view, is to get rid of small local sanitary authorities employing a local part-time medical officer of health. He therefore desires to see an Act framed for England and Wales on lines similar to the Scottish Public Health Act, leaving it to the county councils to prepare and lay before the Ministry of Health schemes for the division of their counties into suitable districts. With regard to a state medical service, Dr. Barwise sees no reason why a scheme should not be evolved for whole-time officers and part-time salaried medical officers which would be acceptable to the profession while getting rid of the panel system. He suggests that the duty be put upon each county and county borough council to prepare and lay before the Ministry of Health a scheme for providing a number of medical institutions to carry out the work of treatment not only for insured persons, but for their dependants. Each institution should have a whole-time medical staff and specialist officers, who would also be the school medical officers of the district. The remainder of the staff would be part-time officers allowed to engage in private practice amongst the non-insured, every practitioner having the right to have his name entered on the roll of part-time doctors. Each institution should have a small clinic fitted up with the latest medical appliances, and a few beds for operation cases. These clinics should, he thinks, serve also as school clinics, and the ophthalmic surgeons, ear and throat surgeons, and dentists employed by the education authorities should form part of the staff, and so be available for insurance persons. He suggests that existing institutions could be taken as the nuclei of this scheme. In the first instance each panel doctor would have transferred to the institution the whole of his panel. The doctors, whether whole time or part time, would be paid fixed salaries, their clerical work being eliminated as far as possible. "The doctor must be placed in such a position that he can tell the patient the disagreeable truth," Dr. Barwise claims that a scheme for providing treatment on these lines would not disorganize the present arrangements under the Insurance Act. For the carrying out of the details of the curative work of insured persons and their dependants joint committees might be formed of the Insurance Committees and the county councils.

Scotland.

THE MORISON LECTURES.

THE Morison Lectures before the Royal College of Physicians of Edinburgh will be delivered this year by Dr. J. J. Graham Brown, lecturer on neurology in the University of Edinburgh. The course will deal with certain disorders of the sympathetic and parasympathetic systems according to the following synopsis:

The general arrangements of the two divisions of the autonomic system, sympathetic and parasympathetic (cranio-bulbo-sacral division); their functions; their antagonism; their synergic action. Certain disorders of the sympathetic division; their signs and symptoms; their treatment. The parasympathetic division; arrangement of neurones; adequate stimuli under normal conditions; causes of over-stimulation leading to hypertonicity; signs and symptoms of that condition; clinical tests; special diseases to which hypertonus may give rise; their appropriate treatment.

The lectures will be given at the College at 5 p.m. each day, the first on Monday, March 4th, and the second and third on Wednesday and Friday.

THE PROPOSED MINISTRY OF HEALTH.

At a meeting of the Fellows of the Royal College of Surgeons of Edinburgh, on February 5th, the council presented a report on the proposals for a Ministry of Health, more especially in relation to Scottish requirements. After discussion, a number of recommendations were unanimously adopted and embodied in a circular which has been sent to the Prime Minister, the Scottish Members of Parliament, the deans of the medical faculties of Scottish universities, medical corporations, Government departments, and other bodies. The College cordially supports the proposal to form a Ministry of Health having full powers (under parliamentary control) to deal with all matters bearing upon national health. It recommends that there should be a separate Ministry for Scotland with direct parliamentary representation, but, in view of difficulties in the way, expresses the opinion that the desired purpose might be secured by an extension of the duties and powers already entrusted to the Scottish Local Government Board, with the Secretary for Scotland as Minister of Health. It submits that before any bill is introduced the College and other bodies representative of the medical profession should be consulted as to its terms, and that it is inexpedient to complete the necessary enactments before the end of the war. It would be deplorable if legislation, hastily introduced without previous consultation with those who must be concerned in giving it effect, should occasion controversy between the medical profession and the legislature. At the present time the medical profession is very largely employed on naval or military duty, or otherwise preoccupied by work arising out of the war. At a meeting of the St. Andrews University Court on February 8th, it was decided to represent to the Secretary for Scotland that before any measure for the establishment of a Ministry of Health is introduced in Parliament the proposals should be submitted for the consideration of the medical profession and of the medical licensing bodies.

South Australia.

MEDICO-POLITICAL.

IN the local Parliaments two interesting Acts have been passed. One has abolished not only the exemptions of the Vaccination Act of 1882 but the compulsory clauses also. The Act had become such a dead letter that the Government was advised that it would get just as good results if it substituted a clause which allowed a proclamation to be issued compelling contacts, in the event of an outbreak of small-pox, to be vaccinated. This is a compromise, and it remains to be seen how it works in practice. The chief feature of the debates, however, was the enunciation of his objections by the new Agent-General.

the Hon. E. Lucas, M.L.C. It is difficult to understand how, in the twentieth century, a man of intelligence can entertain such ridiculous theories as he did, backed up by most quaint references to antivaccination literature. Mr. Lucas was responsible in another bill (the Criminal Law Amendment Act) for a clause which he carried through the Upper House, but which was rejected by the Commons, to the effect that a penalty in certain sexual offences should be "emasculatation." The Act provides for the detention of a criminal found suffering from venereal disease after his sentence has expired and until he is cured. The Government has found time to pass an amended Dental Act, but has been unable to devote a minute to the still more urgent need for an amended Medical Act.

An interesting event was the Medical Referendum held in June last. It yielded an affirmative vote of just under 75 per cent.; a fraction more and the Commonwealth would have been invited to conscript the medical profession for service at home and abroad. It is gratifying to know that the highest percentage in favour of such service was recorded by South Australia, the totals being "Yes" 122, "No" 20. This year (1917) has also seen a *modus vivendi* arranged by a Labour Minister (Mr. Blundell), as representing the Friendly Societies' Medical Association, and the British Medical Association. The arrangement seems to be satisfactory, and apparently the services of those who came some years ago from various parts of the earth to take the place of Adelaide doctors will no longer be required.

THE BRANCH.

The South Australian Branch of the British Medical Association flourishes under the renewed presidency of Dr. J. C. Vero. It has had some severe losses, however, during the past year. Dr. C. E. Todd was a member of thirty-four years' standing. A native of Adelaide, a son of the late Sir Charles Todd, K.C.M.G., F.R.S. (for many years Postmaster-General and Government Astronomer), he started in practice with many advantages. Step by step he attained, though after many years, to the height of his ambition—a hospital surgeoncy. He was beloved by his numerous patients, and was especially useful as president of the branch of the Australian Trained Nurses' Association. In 1901 he was President of the Branch of the British Medical Association. He died suddenly of some obscure brain trouble, possibly abscess associated with frontal sinusitis, whilst away on a holiday. His remains were cremated, and a large attendance at the funeral service in St. Peter's Cathedral bore witness to his popularity. Dr. A. H. Gault was a physician to the Adelaide Hospital, and had practised in a suburb of Adelaide for thirty years. A victim to "horse" asthma he was one of the earliest to run a motor car, especially necessary for his work in the hills, where he established a sanatorium for phthisis. Dr. Hunn of Booleroo Centre seemed to have a great future before him when he succumbed to tuberculosis. The mysterious disappearance of a steamer on its way to Papua accounted for the death of Lieut.-Colonel Strangman and Major Flood. At the front there have fallen Captains Gilbert Harvey, Shierlaw, Lucas, and Burden.

Looking on the brighter side it is to be noted that a shower of honours has fallen on the Branch. Professor E. C. Stirling has received a knighthood respecting which it is difficult to say to what special branch of science it may be assigned. Dean of the Faculty of Medicine and Professor of Physiology in the University, sometime Assistant Surgeon to St. George's Hospital, London, and Surgeon to the Adelaide Hospital, though he never engaged in private practice, ethnologist, biologist, palaeontologist, Fellow of the Royal Society of London, it may be said of him, *nihil telegit quod non ornavit*.

Colonel Hayward's work at Harefield Hospital, and Colonel H. A. Powell's at the front have been rewarded with the C.M.G., whilst Lieutenant-Colonel de Crespigny, Lieutenant-Colonel Fry, and Major Jeffries have gained a D.S.O.; several have been mentioned in dispatches, including Lieutenant-Colonel Newland, whilst Captains Beard, Birch, Kenilham, Wall, Wyllie, and Steele, have received the Military Cross. Of the last batch of fifteen graduates three have joined the Australian navy and the rest the army.

Correspondence.

ARMY MEDICAL RECORDS.

SIR,—I was glad to read in the BRITISH MEDICAL JOURNAL of February 16th your comments regarding the vexatious clerical work involved in the making of army medical records. You refer to the new system lately devised for the Army Medical Service by the statistical department of the Medical Research Committee. I distrust these new army systems. My experience is that they mean the retention of the old evils with the addition of extra burdens. As regards the overseas records, it must be admitted that the adoption of the field medical cards is all to the good. But how about the home hospitals? As far as I can see, the only change we have under the new system is the addition of the troublesome index card, with its wholly inadequate questions. When will the authorities learn that it is often impossible to give an accurate description of a case by question and answer? What is required is a short summary in the medical officer's own words; this, as a matter of fact, he already has to make on the medical history sheet, and now we have, "in order to spare us clerical work," the index card superadded.

Of course, the obvious way to deal with the matter is to have two documents, and two only—(a) for overseas, (b) for England. The field card already in vogue would form (a). Notes of the case whilst in English hospitals (either on the present case sheets, or on suitable cards, or in a booklet) followed by a summary would constitute (b); (a) and (b) could then be attached at the termination of the case and would form a complete record. The statisticians would in this way have their summaries, and when they wished to do so could refer to the fuller notes. This appears to me to be very necessary if the statistics are to have any value. If the booklet form were adopted, a pocket might be provided to contain the field card.

Another matter arising from this—diet sheets, the bugbear of the M.O. at home hospitals, who frequently is doing heavy civil work in addition to his military duties. In France at base hospitals, under exactly similar conditions, the individual diet sheets are abolished and one diet sheet kept for each ward. Why cannot this be done here? No one can have any intelligent use for the individual diet sheets, which consume vast quantities of paper and usually end their life ignominiously in a lumber cupboard. All the details required for the quartermaster's department are supplied by the daily summaries from each ward. The fetish of the diet sheet has reached such a pitch that recently in a large war hospital a two months' collection of these documents was returned by order of the higher powers to the M.O.s. to be added up. This is not so simple as it looks when one is dealing with broken periods and fractions in avoirdupois and fluid measures. Even if it has to be done, surely a clerk whose work it is to deal with figures will make a much better job of it than the average medical man; moreover, he will cost considerably less.—I am, etc.,

February 19th.

HOSPITAL SURGEON.

"CRAVING" FOR DRUGS.

SIR,—In the BRITISH MEDICAL JOURNAL of February 9th, in the leading article, you state that I said that there was a craving for morphine and bromide in my evidence in the insurance case. What I particularly stated was that there was no craving for bromide like there is for chloral and morphine.

My experience of veronal is too limited to enable me to state whether there is a craving or not, but I have seen many patients who have taken it and found no desire to go on taking it.

But my experience in bromide is very extensive, and I have particularly observed the question of craving, and I can say with absolute confidence that there is no such thing as a craving for bromide. Time and again I have had patients taking it for many years, and they have stopped it abruptly, and have not had the slightest desire to resume it.

I would not think it necessary to trouble you with this letter but for the fact that I know that there are some

people who have warned patients of the danger of taking bromide lest they should create a habit, and I have seen many patients who have been prevented from having the benefit of the drug because of this fear.—I am, etc.,

London, W., Feb. 19th.

J. MACKENZIE.

** We are glad to publish this explanation, for the reports of the case in the newspapers were concordant as to the reference to morphine, but were discordant as to attributing to Sir James Mackenzie the opinion that the craving might exist for bromide.

DIET, STARCH, AND SUGAR.

SIR,—In answer to Dr. H. Campbell's question respecting the diet of diabetic patients previous to the onset of the disease, I think we have grounds for considering that excess of sugar and sweet food is probably injurious, but that a diet of starchy food is not specially injurious as a predisposing cause, or, at least, is much less injurious.—I am, etc.,

Manchester, Feb. 18th.

R. T. WILLIAMSON.

POSSIBLE DEVELOPMENTS OF TRANSFUSIONS.

SIR,—Anyone who has carried out a series of transfusions by the multiple syringe method must be impressed by the total absence of injury to the donors. One man has given blood from the same vein upon eight occasions, and expressed himself willing to continue at intervals of fourteen days for an indefinite period. The patient, too, suffers little or no inconvenience. A register of suitable donors, classified under their blood groups, is being prepared at the London Hospital, in order that all cases in which transfusions are indicated may be treated without delay.

These advantages led me to suggest that in cases of severe infection, in which the patient derives no benefit from injections of vaccine, it would be wise to obtain a donor of the same blood group as the patient, and give him injections of the patient's autogenous vaccine. When an immunity has been developed a series of transfusions might be given. The dose would be multiples of 600 c.cm. and not of 10 c.cm., so that even if the concentration of the antibodies in the blood be low, nevertheless a considerable quantity would be introduced.

It must be borne in mind that rabbits and horses do not develop much antibody for streptococci, but it does not follow that man, too, is unable to make these substances.

The procedure is so simple that it must have occurred to many, and perhaps those who have carried it out would be willing to record their results, giving every detail, so that time need not be wasted repeating experiments if they have already proved unsuccessful.

The idea is capable of further development, and perhaps some day we shall reduce still further the mortality due to diphtheria and tetanus by having donors immunized against these bacilli, and using their blood for transfusions in cases of very weak children, and when previous injections of horse serum would lead to anaphylaxis, or serum sickness to fatal results.—I am, etc.,

London, W., Feb. 15th.

O. LEYTON.

PROPHYLAXIS IN VENEREAL DISEASE: ITS FALLACIES.

SIR,—The experience of Mr. E. B. Turner, F.R.C.S., which you published last week, is most helpful, and his conclusions are exactly those to which I have been driven.

Incalculable evil will be done both to the army and the civil population if we profess to be able to divest indiscriminate intercourse of its inevitable dangers.—I am, etc.,

J. C. McWALTER, M.D. Captain,

February 17th.

Specialist Sanitary Officer.

THE AUXILIARY R.A.M.C. FUNDS (OFFICERS' BENEVOLENT BRANCH).

SIR,—May I correct an error in your note on this subject on p. 217 of the JOURNAL for February 16th? There is no rule that orphans of officers who are non-subscribers shall have no claim on the benefits of the Fund. The orphans of any of the specified R.A.M.C. officers are eligible to receive benefits.

During 1917, 125 officers whose orphans would be eligible were killed, and there must have been large numbers in 1916 and 1915. Claims on the Fund will be gladly considered if addressed to the Honorary Secretary at the offices of the Funds, 11, Chandos Street, Cavendish Square, W.1.

The Fund (Officers' Benevolent Branch) is for the benefit of orphans of R.A.M.C. officers in the Special Reserve, Territorials, and those holding temporary commissions.—I am, etc.,

W. HALE WHITE, Colonel R.A.M.C.(T.),

London, W., Feb. 18th.

Honorary Secretary.

** We are glad to know that this rule, which appeared in the draft scheme, has been deleted.

Obituary.

THE death has occurred of Dr. WILLIAM JOSEPH SEWARD, formerly medical superintendent of Colney Hatch Asylum. He received his professional education at University College Hospital, and obtained the M.R.C.S. and L.S.A. diplomas in 1875, graduating M.B.Lond. in the following year. In 1878, immediately after completing house appointments at the Bristol Royal Infirmary, he was appointed assistant to Mr. W. G. Marshall at Colney Hatch. Later he became assistant to Dr. Edgar Sheppard, one of the first lecturers on psychological medicine at a London medical school. In 1882, when barely thirty years of age, he succeeded Dr. Sheppard as the medical superintendent. When the London County Council assumed the government of the London (then the Middlesex) Asylums under the Local Government Act of 1890, Dr. Seward was appointed, upon the retirement of Mr. Marshall, to be the administrative medical head of the whole institution, taking over the care of both the male and female sections, and thus ending what had until then been a dual control. During his period of service was inaugurated the After-care Association for the rehabilitation into social life of those patients who had been discharged recovered, and he continued throughout his life to take the deepest interest in the society's welfare, as he also did in the Asylum Workers' Association, of which he was a member of the executive committee. In January, 1903, a destructive fire occurred in the new wooden annexe, adjacent to the main buildings of Colney Hatch, which was demolished in about an hour. In this fire fifty-one female patients lost their lives and the rest were saved with difficulty. This disaster cast a deep shadow upon Dr. Seward's life, and he never recovered from the shock.

Sir ROBERT ARMSTRONG-JONES, to whom we are indebted for the foregoing particulars, writes as follows:

The treatment of the insane under Seward's régime was always one of enlightened and disinterested progress, and the writer of this article is under the greatest obligations to the memory of his old chiefs, Marshall and Seward, for their high example of devotion and attachment to their patients, whilst the welfare of the staff never escaped either of them. Alcohol, in the shape of beer, was abolished as an article of diet under Seward; the Turkish bath for restoring mental patients was first used there; organo-therapy was encouraged by him, and the aid of clinical pathology with the application of the microscope were all adjuncts in treatment which were of intense interest to Seward, and they continued to be aspects in the practice of medicine which engaged his leisure and retirement, for he was a frequent visitor at the meetings of the Royal Society of Medicine, of which he was a Fellow. Seward was an "intermediary" between the old school and the new research one first started in the London asylums by Sir William J. Collins. Nothing was irksome to Seward, and his mind may be described as healthy in the best sense. He was a Mason, and a member of the London County Council Lodge. He was a keen angler, and was devoted to Norway, where he used to fish, and to Switzerland, where he made many walking tours. He liked a game of whist, and he was a real cricketer—preferring rather to play in a small match than to watch the great ones—although he was often seen at Lord's. He was fond of pictures, and rarely missed an exhibition in Bond Street; he was

devoted to his garden, and he delighted in the cultivation of roses, whilst he derived great pleasure from the meetings of the Royal Horticultural Society. Seward's mind was not that of a controversialist, indeed he rather disliked debated questions, but he always expressed his opinions—which were well considered—both critically and fearlessly. His great charm was his complete detachment from bias—he had cultivated the bias of anti-bias more than any other man of the writer's acquaintance, and he was a most genial, well-informed and cheerful personality. He always maintained the complete confidence and friendship of his committee as well as of their officials.

DR. GEORGE STOKES HATTON, who died on January 15th at Wimborne, Dorset, was for many years a well-known practitioner in North Staffordshire, until failing health caused his retirement to the South of England. After studying medicine at St. Thomas's Hospital and at Newcastle-on-Tyne, he obtained the diplomas of L.S.A. in 1879 and M.R.C.S. in 1880, and graduated M.B., M.S. Durh., proceeding M.D. in 1882. In 1894 he became F.R.C.S. Edin. Dr. Hatton held resident posts at the North Staffordshire Infirmary, and, on his leaving there, joined Dr. Orton in practice at Newcastle-under-Lyme. He was soon appointed to the assistant staff as surgeon to the infirmary, and in turn became full surgeon, and then was appointed consulting surgeon on leaving the district. Dr. Hatton was a successful practitioner and possessed surgical skill and dexterity to a marked degree. His death will be regretted by a large circle of patients and friends in North Staffordshire.

THE death occurred on January 28th of Dr. GEORGE HENRY ECCLES, aged 76, who had practised in Plymouth for over fifty-five years. After studying at St. Bartholomew's Hospital, Dr. Eccles obtained the M.R.C.S. diploma in 1862, the L.R.C.P. Edin. and the L.S.A. in 1865. Having held the post of house-surgeon at St. Bartholomew's Hospital, he set up in practice at Plymouth, where he held a considerable number of appointments as surgeon to charitable institutions. Dr. Eccles was a man of remarkably strong character and sacrificed much for his religious convictions. He leaves three sons in the medical profession: Dr. G. Tolcher Eccles, of Hove; Captain H. Nisbet Eccles, R.A.M.C.; and Captain G. Dunlue Eccles, R.A.M.C.

DR. WILLIAM CARDIFF HOSSACK, port health officer of Calcutta, died in Calcutta on January 5th. He was the eldest son of Mrs. Garden Milne Hossack, of St. Catherine's, Banff, and was educated at the University of Aberdeen, where he graduated M.B. and C.M., with honours, in 1894, and M.D. in 1898. For the last twenty years he had served in Bengal, where he had held the posts of special plague officer, health officer to the Corporation of Calcutta, district medical officer, and health officer of the port of Calcutta. He was the author of a monograph on the rats of Calcutta.

BRIGADE SURGEON JOHN LAW, Madras Medical Service (retired), died at Guildford on February 6th, aged 83. He was the second son of the late Thomas Hooper Law, of Barnstaple, and entered the I.M.S. as assistant surgeon on May 28th, 1858, becoming surgeon on May 28th, 1870, and surgeon major on July 1st, 1875, and retiring, with a step of honorary rank, on February 1st, 1882. During the later part of his career he held the important appointment of residency surgeon, Hadarabad.

BRIGADE SURGEON WILLIAM JAMES WILSON, R.A.M.C.(ret.), died at Southsea on February 8th, aged 80. He was educated at Queen's College, Belfast, where he graduated M.D. in 1860, and took the diploma of M.R.C.S. in the same year; he entered the army as assistant surgeon on April 1st, 1861, became surgeon on March 1st, 1873, surgeon major on April 1st, 1873, and retired as brigade surgeon on May 2nd, 1888. In the old regimental days he served in the 28th Foot, now the Gloucestershire Regiment, and later he commanded the station hospitals at Portsmouth in 1855-86, and at Mhow in 1887. He served in the Afghan war, in 1880-81, in the Southern Afghanistan Field Force; and in the Soudan in 1885, commanding No. 1 Bearer Company in the Suakin Field Force and receiving the medal with a clasp and the Khedive's bronze star.

DEPUTY INSPECTOR-GENERAL JAMES CRAWFORD DOW, R.N. (ret.), died recently at Bath of congestion of the lungs, the result of an accident, when he fell and broke his leg in a rough sea, returning from Australia last May. He was educated at Glasgow University, where he graduated M.B. and C.M. in 1870, and entered the navy soon after, attaining the rank of fleet surgeon on June 4th, 1893, and retiring, with a step of honorary rank, on September 21st, 1904.

Universities and Colleges.

UNIVERSITY OF OXFORD.

At a congregation held on February 16th the following medical degrees were conferred:

D.M.—W. R. Reynell (*in absentia*), G. T. Hebert.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examination indication:

FINAL M.B., CH.B.—*Part I, including Forensic Medicine and Toxicology*: Elizabeth Casson, A. D. Symons. *Part I only*: B. A. Astley-Weston, A. G. Bodman, R. F. White.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council was held on February 14th, when Colonel Charters Symonds, Vice-President, was in the chair.

Diplomas of membership were granted to eighty candidates found qualified at the recent examinations. Diplomas in Public Health were granted jointly with the Royal College of Physicians to two candidates found qualified.

The Begley Studentship was opened to women as well as to men.

A resolution having been passed by the College of Physicians for the omission of biology from the first professional examination, the subject was referred by the Council to a special committee for report.

The Secretary reported that, in pursuance of the provisions of the new by-laws, the date of the next Council election would be announced by advertisement and by circular on March 8th, and that March 18th would be the last day for the nomination of candidates.

COLLEGE OF MEDICINE, NEWCASTLE-ON-TYNE.

THE council of the college has elected Dr. David Drummond to be president of the University of Durham College of Medicine, Newcastle-on-Tyne, in succession to the late Sir George Philipson, and the chancellor has appointed him pro-vice-chancellor of the university. Dr. Drummond graduated M.D. (Dubl.) in 1876, became physician to the Children's Hospital shortly afterwards, and in 1878 became physician and pathologist to the Royal Victoria Infirmary, and is now consulting physician. He is also joint professor of the principles and practice of medicine in the University of Durham. At the annual court of governors of the college he was elected vice-chairman. At the same meeting it was announced that the number of students at present in attendance was 168, or 26 more than a year ago. The number of women students has increased by 50 per cent., and they now form 25 per cent. of the total. Dr. P. H. A. Clayton has been appointed lecturer in bacteriology, and Dr. Helen G. Clark part-time assistant. The routine work of the department has been increased, as it has been arranged to conduct for a number of urban and local authorities the bacteriological investigations required by the Local Government Board under the venereal disease regulations. Additional accommodation has been provided at the cost of about £600.

CONJOINT BOARD IN ENGLAND.

THE diplomas of L.R.C.P. and M.R.C.S. have been conferred upon the following:

G. V. W. Anderson, Mary Andrews, H. C. Apperly, C. W. W. Armstrong, K. E. Attenborough, Loveday S. Banes, M. Baranov, E. R. Batho, C. C. Beney, P. F. Bishop, J. C. Blake, J. S. Boruchowitz, R. B. Britton, H. S. Bryan, F. Caldecott, G. T. Calthrop, J. D'A. Champney, H. A. Chodak, W. B. Christopherson, A. E. Clark-Kennedy, C. B. Cohen, W. Collins, R. N. Craig, T. L. Crawhall, H. T. Cubbon, Jatindra Kumar Datta, C. Depla, A. R. Doyle, F. B. Dutton, F. N. V. Dyer, Abdel Aziz Hassan El Zenieny, W. Feldmao, A. F. M. Fuoss, G. H. Gidlow-Jackson, Eryl Glynn, W. N. Goldschmidt, W. H. Grace, R. B. Green, W. S. Gross, W. M. Heald, J. M. Higginson, E. A. Holmes, J. Hope, H. B. Jackson, W. A. Jolliffe, D. M. Jones, J. W. Jones, M. E. Jones, T. P. Kilner, D. M. Lalá, F. W. M. Lamb, J. G. Lawn, Marguerite F. J. Lowefeld, G. E. MacAlevey, H. M. Menage, Daisy K. P. Michael, H. Millett, L. M. Moody, D. M. Muir, Annie S. Mules, P. M. Neighbour, Vijaya Shankar Rao Padit, E. J. Papenfus, A. L. S. Payne, T. M. Payne, A. V. Pegge, A. Peioe, Sybil M. G. Pratt, Joyce B. Reed, H. T. Rymer, H. M. Savery, C. K. Seales, G. A. S. Shacklock, B. S. Sharp, A. G. Sherrlock, G. H. Sims, A. R. Totthill, J. T. Wall, A. S. Westmould, E. Wolff, F. G. Wood.

Medical News.

THE fourth meeting of the Inter-Allied Surgical Conference will be held early next month. The last conference took place in Paris in November last, and an account of its conclusions was published in the JOURNAL of January 5th, p. 28.

THE Home Secretary announced in the House of Commons on February 20th that summer time for 1918 would commence at midnight, Sunday, March 24th, and terminate at midnight, Sunday, September 29th.

THE Parliamentary Secretary to the Ministry of Food (Mr. Clynes) has stated that the number of standard barrels of beer brewed for consumption in the United Kingdom during 1917 was 16,133,800, and that the quantity of materials used for the first nine months of the year was 23,620,800 bushels of malt, 61,200 cwt. of rice, 6,200 cwt. of maize, and 1,613,700 cwt. of sugar or its equivalent. He stated also that the quantity of spirits retained for consumption as beverages in the United Kingdom in the year ending December 31st, 1917, was 18,549,406 gallons.

THE delivery of the Hunterian lecture on the pathological aspects of certain war injuries of the eye, announced to be given at the Royal College of Surgeons of England by Colonel W. T. Lister, on February 25th, has been unavoidably postponed until May 8th.

DR. ROBERT A. LYSTER, lecturer in public health and forensic medicine at St. Bartholomew's Hospital, and county medical officer for Hampshire, has succeeded Sir Shirley Murphy as editor of *Public Health*, the official journal of the Society of Medical Officers of Health.

AT a meeting of the Shakespeare Association at King's College, Strand, on Friday next, at 5 p.m., Dr. Ralph W. Litchfield will read a paper on Doctor John Hall, Shakespeare's son-in-law.

THE Fire Brigade Committee has brought to the notice of the London County Council the work of Mr. Somerville Hastings, surgeon-in-charge of the ear and throat department of the Middlesex Hospital, in connexion with a fire caused by bombs from hostile aircraft. In rendering medical attention to a man who was pinned under some debris, Mr. Hastings shared the risks of members of the Fire Brigade, regardless of the fact that he had no helmet or other protection, and that debris were falling.

AT the annual meeting of St. Mark's Hospital for Cancer, Fistula, and other Diseases of the Rectum, City Road, London, when the Lord Mayor was in the chair, it was stated that soldiers suffering from rectal diseases and injuries were being treated, and that so far all had been discharged cured, although it had been necessary to keep some in the wards for as long as four months. An opportunity has occurred to purchase a vacant site adjoining the hospital and an appeal for £4,000 to complete the amount needed is being made.

STATISTICS for the year 1916 of the twenty-six German towns with a population of over 200,000 each show a decline of 38.3 per cent. in the birth-rate as compared with 1914. The figures for August and September, 1916, were, however, better than for the preceding July, a result, it is supposed, of the facilities given to soldiers for Christmas leave.

THE Reichstag debate, in which the patrons of salvarsan were accused of suppressing salvarsan fatalities, and in which the medical journals were said to be accomplices to the unscrupulous exploitation of this drug, has had a sequel. In an order from the Prussian Minister of the Interior, dermatologists, specialists in venereal diseases, and the heads of medical institutions are required to give a return showing the number of patients treated and of injections given, and the nature and number of the ill effects observed. Information is asked as to the benefits resulting from the treatment of syphilis with salvarsan and its derivatives.

THE first general meeting, since the war, of the German Medical Association was held in Leipzig on September 22nd and 23rd, 1917. It was stated that about 24,000 German doctors were engaged on war work, and that about 1,000 had fallen in the field. The attacks of the insurance societies on the medical profession, and the prospect of loss of independence by the adoption of a state medical service were discussed. Bitter conflicts with the insurance societies after the war were foreshadowed. With regard to the establishment of dispensaries for the treatment of venereal disease it was agreed that the medical profession should be adequately represented. Unanimity was also shown in a resolution calling for higher remuneration in every branch of the medical profession in view of the depreciation of the currency.

Letters, Notes, and Answers.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitology*, Westrand, London; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES AND ANSWERS.

VOLUNTEER TRAINING CORPS.

M.O. asks for information as to the conditions of service applicable to the medical officer appointed to a Volunteer battalion. "Everyone," he writes, "seems to agree that the time is not far distant when the Volunteer Force will be mobilized. A medical man is gazetted as 'temporary lieutenant and medical officer.' In his case does length of service qualifying for promotion count from the date of the *Gazette* notice or from the date of mobilization, and is his pay that of the temporary officer or of the Territorial officer?" Authentic information on these points would, he thinks, be of benefit to those who have joined or are about to join the V.T.C.

"LAMBETH DEGREES."

S. N. asks what powers or privileges the Archbishop of Canterbury has with reference to conferring the degree of M.D.

*. The power of bishops to grant licences to practise medicine doubtless originated in the claim of the church, whose authority was embodied in the Pope, to control all matters relating to education. Some historical notes were published in the BRITISH MEDICAL JOURNAL of December 28th, 1912, p. 1766, where an Act of Henry VIII (1511) defining the mode of exercise of the right was quoted. Some twenty years later an Act was passed empowering the Archbishop of Canterbury to grant degrees in divinity, medicine, and arts. These degrees have commonly been known as "Lambeth degrees." Dr. S. D. Clippingdale informs us that the holders wore the same robes as those holding the corresponding degree of the university to which the Archbishop himself belonged. The Archbishop of Canterbury voluntarily surrendered his right to confer the M.D. when the Medical Act of 1858 was passed. In the BRITISH MEDICAL JOURNAL of December 21st, 1912, p. 1718, a licence granted by the Bishop of Norwich in 1561 was quoted in full.

LETTERS, NOTES, ETC.

NEW DIET RESTRICTIONS.

R. J. R. writes to express the opinion that while most people approve of the rationing principle in general they expect an exemption for any particular case in which they are interested, and believe that all that will be necessary is to apply to their doctor for a certificate. "Unless," he continues, "the regulations for special certificates are made very strict and very definite, there is a risk of very extensive evasion of the orders of the Food Controller. The case of milk is, perhaps, the most important, the case of cream and butter being considered with it; but a particularly flagrant example is that of beef-tea. Taking into account the very small food value of this pleasant extract and the proportionately large amount of the best meat sacrificed to make it, it is to be hoped that in this instance the Food Controller's ruling will be almost prohibitive of certificate."

THE ADVANTAGES OF tepid BATHS.

DR. GERALD W. MAW (Bedford) writes to recommend the use of tepid baths both as a war economy and because he believes that many people injure their physical condition by frequent and prolonged bathing in hot water. He quotes the case of

a middle-aged man who consulted him on account of "a feeling of general lassitude, disinclination for exertion, and tendency to take cold." He had complained of this state of affairs for six months, and attributed it to a change of residence from a bracing to an enervating climate. He had always led a regular life, spending a great deal of time out of doors, and had not had an illness for years. His heart was found to be healthy, and so, apparently, were his digestive and excretory organs. The urine was normal. The lungs were slightly emphysematous. The patient stated that until the last six months he had always had his bath cold or tepid. Latterly, having an unlimited quantity of hot water, he had been in the habit of taking a hot bath nightly and staying in it about fifteen minutes. He was recommended to discontinue the hot baths entirely, to sponge rapidly with tepid water at night, and in the morning to immerse himself in a tepid bath, and then sit up in it for three minutes with the cold water tap running. This change soon restored him to his old state of physical well-being.

TONSILS AND ADENOIDS.

MR. H. CLAYTON FOX, F.R.C.S.I. (London, W.), writes to express the opinion that in the correspondence one point as to the etiology of hypertrophied tonsils has been overlooked, or at least not discussed. "I refer to the influence of nasal obstruction, due to any cause, congenital or acquired. Every child with nasal obstruction is a mouth breather, and this means that air laden with microbes (especially in the poorer dwellings) are continually infecting the tonsils, with obvious results. As to treatment, my own experience leads me to believe that nasal obstruction is the prime factor—adenoids should be removed as early as possible, chronic rhinitis treated and followed up by careful and persistent breathing exercises. With a healthy nose and nasopharynx, and, of course, having excluded other sources of oral infection, most tonsils will, unless enlarged by specific fevers, undergo involution in their own good time."

SACCHARINE AND DIGESTION.

COMPLAINTS having been made in Germany of digestive disturbances following the use of saccharine as a substitute for sugar, Professor Best (*Muench. med. Woch.*, September 18th, 1917) has investigated the matter by giving comparative test meals consisting of tea and bread with sugar, or one tablet of saccharine. Analysis of this material taken from the stomach at the height of digestion showed that the total acidity of the gastric juice was considerably greater when saccharine was given instead of sugar. Investigations also showed that, in addition to stimulating the secretion of gastric juice, saccharine probably delayed the passage of food from the stomach. Best concludes that saccharine should be withheld in cases of hyperacidity, and that gastric and duodenal ulcer should certainly be regarded as contraindications for the use of saccharine, which in other respects cannot be regarded as injurious.

MALTHUSIANISM AND MORALITY.

DR. BINNIE DUNLOP (London, S.W.), writes: Is it, as Mr. E. B. Turner states (p. 208), "a fact well known to all social workers that the standard of what I may call practical morality among young women of every class of society has gradually deteriorated since, some twenty years ago, the Malthusian propaganda began and the public display and advertisement of Malthusian appliances followed"? Although for years I have been constantly discussing this propaganda with social workers I rarely before the war heard the suggestion that it had increased promiscuity. Can Mr. Turner produce any evidence that promiscuity had been increasing? Malthusian propaganda began forty years ago.

THE NIGHT SCREAMING OF CONGENITAL SYPHILIS.

THE *Brazil-Medico* of October 20th, 1917, contains a communication from Dr. Cassio de Rezende of Guaratinguetá pointing out that the nocturnal wakefulness and fretfulness with almost continuous screaming which is an indication—often the only one—of congenital syphilis in infants is generally designated in South America as Sisto's symptom, after a distinguished Argentine physician who is believed to have been the first to describe it. Dr. Genaro Sisto, professor of paediatrics in the Medical Faculty of Buenos Aires, wrote much about what he called a new symptom of hereditary syphilis. His first paper on the "syphilitic scream" appeared in *Archivos Latino-Americanos de Pediatria* in 1906; in 1909, in his clinical lectures on infant pathology, he related a case in which he identified the disease by this symptom alone and effected a rapid cure by antisiphilitic treatment. Those lectures were translated into French in 1910, under the title of *Conférences de pathologie infantile*, by Professor V. Intelin, who contributed a preface in which he endorsed Professor Sisto's claim of priority in the description of the symptom. Dr. Cassio de Rezende, however, shows that the symptom was fully described by Eustace Smith in the second edition of his *Practical Treatise on Disease in Children* which appeared in 1870. The symptom is coupled with the name of Eustace Smith by Dr. Robert Hutchison in his *Lectures on Diseases of Children*, published in 1904. Apart from actual attacks of screaming, great restlessness, and irritability at night, often attended by drowsiness by day, ought, if persistent, to arouse a suspicion of syphilis. The cause is probably pains in the bones.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE following subscriptions to the Fund have been received during the week ending February 18th:

	£	s.	d.		£	s.	d.
Dr. John Orr	...	1	0	The Society of Apothecaries of London	...	100	0 0
Dr. Theodore Thompson	...	5	0	Dr. R. Stanley Thomas	...	1	0
Sir Felix Semon	...	2	0	Mr. E. Spencer Evans	...	0	10 0
Dr. W. F. Haslam	...	2	0	The Countess of Leven	...	25	0 0
Mr. W. S. Turner	...	0	6	and Melville	...	25	0 0
Mr. F. P. Sergeant	...	0	10	The Lady Betty Leslie	...	25	0 0
Mrs. Des Vœux	...	5	0	Melville	...	3	0
Surgeon-General F. J. Lilly, R.N.	...	2	2	Mr. H. Gaselee	...	3	0
Royal College of Physicians of Edinburgh,	...			Miss May Rathbone	...	6	6 0
per Dr. Norman	...			Major G. Grey Turner, R.A.M.C.	...	6	6 0
Walker	...	26	5	Dr. F. W. Goodbody	...	2	2 0
Dr. Boodle	...	0	7	Mr. H. James Kluge	...	3	3 0
Dr. Des Vœux	...	25	0	Mr. J. R. Reith	...	1	1 0
Sir F. Needham, M.D.	...	5	0	Dr. J. M. Chisholm	...	2	2 0

* Monthly donation during the period of the war.

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

PRESCRIPTION WRITING IN THE METRIC SYSTEM.

DR. SYDNEY WHITAKER (Liverpool) writes: This method of expressing the dosage of drugs has happily come to stay, but at present it is hindered by lack of uniformity. For example, students of the Liverpool University are taught to express quantities by certain symbols; in Bruce and Dilling's *Materia Medica and Therapeutics* one finds other symbols, while in H. A. Hare's *Textbook of Practical Therapeutics* yet other symbols are used. Thus, for example, the following prescription would be written in the following ways:

	Imperial Measures.	Metric Measures.		
		Liverpool University.	Bruce and Dilling.	H. A. Hare.
R. Vin. colch.	m xv	1 mil	Ml 1	Cc 1
Mag. carb. p.	gr. x	6 deg	Dg 6	Gm 0.6
Mag. sulph.	gr. xv	1 grm	G 1	Gm 1
Aq. menth. pip.	ad 5 i	30 mls	Ml 30	Cc 30
Mitte	5 viij	240 mls	Ml 240	Cc 240

As if to add to the confusion, it is customary in most countries in which the metric system is used to express the dose of liquids by weight, while many French physicians would, I believe, express the above dose of heavy magnesium carbonate thus, 0.6 décigram. It would be well if English and American teachers of and writers on materia medica and therapeutics could come to some agreement, and bring the matter before the next International Medical Congress for settlement.

A DISCLAIMER.

LIEUT.-COLONEL C. S. MYERS, F.R.S., R.A.M.C.(T.C.), (Moss Side Military Hospital, Maghull, near Liverpool), writes: My attention has been called to an appeal for funds now being circulated by the Medico-Psychological Clinic, Ltd., in order that it may deal with "the tens of thousands of our bravest heroes . . . discharged from the navy, army, and air service, useless and helpless, suffering endless torture from such maladies as insomnia, states of anxiety and exhaustion, uncontrollable emotions, . . . etc." In this circular I am described as one of the two consulting physicians to the clinic. Will you allow me to state that this use of my name is wholly unauthorized, and that only once—four years ago—have I had any relations or communication with the clinic, when I was invited by letter to join the staff, and sent a written reply declining to do so?

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	...	0	6 0
Each additional line	...	0	0 9
Whole single column	...	4	0 0
Whole page	...	12	0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

Observations ON THE NATURE AND SYMPTOMS OF CARDIAC INFECTION IN CHILDHOOD.

BY
I. J. POYNTON, M.D., F.R.C.P. LOND.,

PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; SENIOR PHYSICIAN TO
JULIENHUIS, THE HOSPITAL FOR SICK CHILDREN,
GREAT ORMOND STREET.

I.—INTRODUCTORY.

THE study of cardiac infection in childhood has appealed to me as the best introduction to the problems of cardiac disease in man. It is, in my opinion, a drawback to our excellent manuals upon heart disease that they do not sufficiently throw into prominence this aspect, and lack that close analysis of the early stages of these infections which makes us realize their great significance and impresses upon us that rational treatment must lie in prevention. The result has been to lay overmuch emphasis upon mechanical problems and to place in the background the more important consideration of the behaviour of the heart in response to infection compared with the response of the other organs. In childhood we can study the commencement of a class of cardiac diseases which often leaves lifelong scars, and both histological and experimental investigations have made it possible to outline clearly the steps in its pathological progress.

From such an introduction as this the student can rapidly grasp the great principles involved, and thus more easily fit into their proper position the many difficult details of cardiac disorders in the adult. Some of these, no doubt, are not concerned with cardiac infection, but none the less they are seen more clearly when these processes are understood.

There are many kinds of cardiac infection, to mention only the rheumatic, tuberculous, septic, diphtheritic, and pneumococcal forms, but for my purpose none is so suitable as the rheumatic. It is in this country the commonest. It attacks all parts of the heart and produces every sort of cardiac disability. The fatality is sufficiently great to furnish accurate pathological knowledge of the injuries, and these have been confirmed by experiment. The student will accordingly start from a broad and solid basis of fact. From the outset two chief considerations will claim his attention: the cardio-vascular apparatus itself, the mechanism of which has been injured, and the correlation of the cardiac disorder with that produced in other organs by the same disease in its various stages.

In the first direction he will be continually acquiring special knowledge of the symptoms and signs of cardio-vascular injury; in the second he will be working on broader lines and studying the cardiac lesions as particular results of the general disease, and will consequently be led to inquire into the life-history of the infection as it concerns the entire system. Thus from the outset he will recognize that much heart disease is the result of the scars of healed infective processes.

During the years I have served as an out-patient physician at the Hospital for Sick Children I have accumulated a large number of clinical facts upon the early phases of cardiac infection, and have, I think, been able to keep them in their right perspective by a simultaneous experience of adolescents and adults in general hospitals. The point of view in these two institutions is not quite the same. In the hospital for adults it is heart disease which is predominant, if only for the valuable teaching it provides. In the children's hospital it is the particular infection that is dominant. Each aspect has its value.

The following examples will indicate the direction in which I am aiming. In this country there is, I suppose, no more serious affection of the heart than mitral stenosis. It is frequent in occurrence, incurable, and a common cause of death under 45 years. The suffering entailed is often extreme, and many married women of the poorer classes are rendered helpless invalids at an age when young families are dependent upon their activities. In a general hospital we usually see these cases with the symptoms well established, and they are looked upon as cases of primary heart disease—that is, as cases of mitral stenosis.

In a children's hospital we see the early stages and attendant circumstances, and we trace their evolution. Again, we may see a case of valvular disease which at the moment is of no particular interest, but if we have followed the history we may have noticed that the lesion followed upon clear evidence of a sore throat. We are thus led to recognize the relation of angina faucium and rheumatic heart disease, and get a glimpse of one of the most valuable lines for preventive treatment that modern medicine has established. Here I would emphasize the value of studying not only the cardiac signs but all the events that may coincide with a first attack of rheumatism in childhood. If we wish to prevent cardiac infection every detail concerning the lesions in other organs becomes important.

There is a warning concerned with nomenclature that should be given to a student who would follow along these lines. The disease is variously called rheumatic fever and acute rheumatism. Both these terms were in use before the disease in the young was understood, and they are sanctioned by long usage. Nevertheless they are misleading. If we consider for a moment tuberculosis in the child, we recognize an acute miliary form, rapidly fatal, acute bronchopneumonic forms, and a large group in which the invasion is so gradual that none can name the exact date of onset. So, too, with rheumatism, there are acute fulminating cases, acute cardiac cases in which the heart takes the position of the lungs in tuberculosis, and cases very gradual in onset.

The terminology of tuberculous fever, or acute tuberculosis, does not cover that disease in the young, and the same is true for rheumatism. This imperfection, however, is not academic in its drawbacks, for the faulty nomenclature leads to surprise being expressed by parent and student that a case of obvious rheumatic disease has never been acutely ill. Moreover, a false notion exists in the lay mind that rheumatic fever is dangerous and that insidious rheumatism is not. One of the difficulties in the prevention of rheumatic heart disease is the unobtrusive onset of some of these illnesses. We can best combat the difficulty by a careful study of the manifestations of rheumatism uninfluenced by the nomenclature.

MANIFESTATIONS OF RHEUMATISM.

There are many admirable articles upon the manifestations of rheumatism in childhood which must be looked upon as introductory chapters to the study of cardiac infection, and some of these manifestations I take here to illustrate what I mean by the correlation of cardiac symptoms with those in other organs. There is, however, one generalization to be made first: *The severity of the cardiac affections is dependent upon the virulence of the infection.* Severe valvular disease may certainly result from repeated attacks of rheumatism, but the deadly menace to the heart lies in the grave toxic forms which from the first irreparably damage the neuromuscular tissues. In such cases this element of virulence is of more importance than the physical signs of cardiac disease for arriving at the immediate prognosis.

A. The Throat and Nose.

In 1900 Dr. Paine and I isolated from the tonsils of a patient suffering from acute rheumatism and tonsillitis a strepto-diplococcus identical in characters with one we had already isolated from the blood, valves, pericardium, joints, and nodules of cases of rheumatism. This produced carditis arthritis, and the various other experimental results we have fully described elsewhere. Some years later we continued these investigations in cases of recurrent rheumatism with diseased tonsils, and confirmed the accuracy of our observations.

The conclusion from these results is obvious: *The infection may gain access to the body by way of the tonsil.* These investigations were novel, but the inference had been suggested and commented upon by clinicians for over a century. As for the clinical evidence, I am convinced it is final. Over a period of nearly twenty years I have assured myself of its truth, and I can recall cases in childhood in which acute rheumatism has followed tonsillitis as clearly as it has followed an experimental intravenous injection in an animal.

Difficulties have been raised, but the chief of them appear to me dependent upon a too rigid interpretation of the processes of disease in man. It has been pointed out

that a sore throat is frequently absent, and this is certainly true. Does any one, however, suppose or claim that no other site of entrance is possible? Again, is it necessary that the throat should be painful? It would be clearly unscientific to claim the tonsils as the site of entrance when nothing points in this direction, but, on the other hand, it would be equally so to deny that structures of which we can only see the surface may not be diseased in their depths, or that a virulent infection may start from a minute and apparently painless local lesion.

When the treatment of infective cardiac disease is discussed, the operative indications in rheumatic tonsillitis require consideration; but here I would point out that with this question also an over-rigid view of human disease is liable to appear. No operation will altogether prevent a recurrence of active rheumatism, and we cannot expect that it would, seeing that we do not know all the various paths of infection or the possibilities of the lighting up of foci of previous infection within the body.

One lesson in the history of heart disease, however, can be safely learnt. *An acute tonsillitis in a child should always call for careful examination of the heart.* A second, equally important, is that recurrent sore throats in childhood are not only in themselves painful and disabling, but are a menace to the heart, and must be a consideration in advising upon operative measures.

In accord with our experience of other infections, there is no condition of the tonsils that can be claimed as specifically rheumatic. In various diseases we recognize clinical forms of sore throat which represent a classical type, but we also recognize that there are variants. In rheumatism we see the painful red glazed tonsils and fauces, and where the process has sunk deeper small follicular deposits; but we also find membranous tonsillitis, sometimes not very unlike the diphtheritic; and again, deep collections of unhealthy secretion in large tonsils which, except for their size, may show little change. It is reasonable to believe that the micrococci are present in the healthy and that they acquire their special virulence under circumstances of lowered resistance, particularly in those who inherit that peculiar constitutional tendency which we call the rheumatic.

These unhealthy conditions of the throat are, we know, often coupled with adenoid vegetations, and it is very probable that in these vegetations the micrococci may retain their virulence. Chronic nasal affections, too, I think, require more observations than are at present at our disposal. The nasal mucous membrane may well be another site of infection, as also the internal ear, and I am convinced there is a rheumatic otitis of acute nature. Enlargement of the cervical glands is common, as would be expected since tonsillar disease is so frequent in the rheumatic, and this must be looked upon as evidence of the entrance of infection into the system. I am a little surprised that more attention has not been directed to the glandular enlargement in rheumatic children, for, though it is naturally to be expected, it accords so closely with the history of other tonsillar infections that its occurrence strengthens our confidence in the infective nature of the disease.

B. Arthritis.

Arthritis in childhood, with which I associate muscular pains, is, as we know, very frequent in rheumatism, and on this account a very valuable danger signal. Although arthritis at this age is not usually severe, the value of it as a symptom is very great, particularly if it is realized that the pain may be considerable owing to implication of surrounding tendon sheaths, with no detectable changes in the joint affected. The rule has been long established that *obscure pain in the joints and muscles in childhood should call for a careful examination of the heart*, and it needs no labouring.

C. Chorea.

Chorea and the allied nervous symptoms deserve the closest attention. I believe there is much to be learnt from their study that has bearing upon some of the most difficult problems in cardiac disease. Later, when touching upon mitral stenosis, I shall illustrate the close association that exists between chronic and repeated chorea and the evolution of this lesion, but now I only wish to draw attention to the great influence that the rheumatic infec-

tion exerts upon the nervous tissues. Chorea is the classical and striking manifestation, but there are other remarkable results. The older clinicians realized that the rheumatic child was the nervous child of a family, and we may look upon this peculiarity from two aspects: The child of rheumatic parentage may have, as one evidence of the constitutional weakness, an unstable nervous system, or, on the other hand, a child who has been attacked by this infection may as a result become unduly nervous. Of this latter occurrence I have no doubt, and I have seen repeated examples in children who have never developed a frank chorea. Such children become prone to migrainous headaches, night terrors, emotional attacks, and general nervousness. They may develop a condition which in adults we might term neurasthenia. Again, striking evidence upon this point is sometimes given by rheumatic adults both male and female. They may volunteer the statement that they know they are highly nervous and have noticed this to increase so greatly when they have signs of active rheumatism that they are then almost unable to control themselves. Such patients possess often enough great will power, and are perfectly aware of their weakness, and their statements convince me of the powerful effect of the rheumatic poison upon the higher nerve centres, and I think it worthy of the careful attention of neurologists. It is well known that every case of chorea requires careful examination of the heart; but the point which I am anxious to insist upon here is that the peculiar effect of rheumatism upon the nervous system tends to produce disturbances of the heart, such as tachycardia, preërdial sensations, irregularity of action, and even arrhythmic symptoms. I believe that above all affections rheumatism is liable in the adult, under suitable circumstances, to produce a condition of the heart akin to that met with so often in the soldier, and that we must keep before us this difficult problem of the factor of nervous instability in the study of organic heart disease. We shall then realize how very difficult it is to distinguish between functional and organic disturbances of this organ, and how inadequate any set tests for the mechanical power of the heart must be in dealing with the practical issue. The problem involved is not only whether the heart is mechanically sound, but whether the individual possesses a heart which will answer to physical and nervous strain by a healthy and confident response.

I have met with rheumatic cases in which the heart has seemed to physical examination but little if at all damaged, and yet such is the neuro-muscular response to sudden physical strain or excitement that they are totally incapacitated for any prolonged exertion, speedily collapsing with palpitation, general prostration, and even syncope.

Rheumatism probably gives us the best clue to unravelling functional nervous disturbances of the heart that we at present possess.

D. Cutaneous Manifestations.

The various rashes and cutaneous manifestations of rheumatism are, I think, of particular interest in that they give us a hint as to the nature of the rheumatic poisons of which we have no accurate knowledge. The urticarial, erythematous, and purpuric lesions suggest an altered state of the blood producing undue fragility or permeability of the capillaries. So narrow is the margin that a hot compress placed over an area of erythema may cause it to become purpuric, and an erythema on the upper limbs may be followed by a purpura on the lower. I have seen an erythema, purpura, and early psoriasis in the same patient—and an erythematous patch with a nodule in its centre. The latter occurrence is of interest, for the nodule is a local infection.

Akin are Filatow's or Osler's spots—on the pads of the fingers or toes, on the dorsum of the hand, or even in the palms and on the wrists. These may be the first definite signs in childhood of a progressive or malignant endocarditis. They are very likely to be overlooked, for they are minute and often so little painful as to escape the child's attention.

In this section I am also inclined to place epistaxis, so frequent in the rheumatic child, as Dr. Sidney Phillips has observed. The attacks may be frequent and severe, but personally I have not met with a dangerous case. It may occur during an acute attack, or be a first warning, or be an isolated event between attacks of general rheumatism.

E. Abdominal Symptoms.

The occurrence of abdominal symptoms in the rheumatic is an obscure subject, but one of considerable interest in heart disease, for we recognize how gastric and other abdominal disturbances influence the action of the heart when it is organically diseased or functionally defective. Reliable evidence upon these symptoms is scanty, for in rheumatism, except in very unusual cases, they do not cause a fatal result. The exceptions are rare examples of acute gastric dilatation and appendicitis. Occasionally extreme pain and distension may be complained of in the line of the colon, producing great distress and embarrassing the damaged heart, and troublesome colitis may occur. Apart, however, from these, we repeatedly meet in rheumatic children with what are called "bilious attacks." The appetite fails, the sclerotics become icteric, and the tongue coated; the motions are pale and there may be vomiting, fever, and severe headache. Such attacks may usher in an exacerbation of rheumatism. Experiment has thrown a little light upon the subject. The diplococcus has been demonstrated in large numbers in the bile of infected animals. Recently, in an unpublished case of fatal chorea in a woman, Dr. Paine isolated the diplococcus from the gall bladder and cerebral tissues. Jaundice, too, is not very uncommon in rheumatic children, and it may complicate the course of a severe chorea.

The bearing of these few observations at present is, I admit, problematical, but we are well aware of the close connexion between hepatic disturbances and the nervous system, and it is quite possible that they take some part in the unstable nervous state of the rheumatic, and that the metabolism of the liver may have a closer relation to the cerebral processes than is realized.

My chief intention here, however, is to draw attention to the occurrence of this triad of symptoms in the rheumatic: *Instability of the nervous system, abdominal disturbances, and faulty action of the heart.* The student of heart disease will repeatedly meet with this combination of symptoms, and he will find it often enough difficult to decide which system is primarily at fault. Such cases are sometimes conveniently termed "neurasthenia," but we should try to search behind the mystery of this somewhat all embracing term.

F. General Wasting.

This also is a symptom needing close attention. It is not very unusual for a child to be brought to hospital for wasting coupled with a history of indefinite illness, and to find the explanation an insidious rheumatism. Again, during a severe attack general wasting may proceed rapidly. Lastly, this symptom in a child with severe organic heart disease is of great significance, for it may mark the beginning of the last stage of the illness, and indicates failure of the circulation to maintain nutrition even when the child is carefully guarded.

The converse to this is also of value; it is a sign of good augury when a child with rheumatic heart disease begins to gain in weight although the physical signs in the heart may convey no such favourable impression.

A student intent on the study of the heart alone, is in danger of losing sight of such homely evidence as this unless he remembers that the heart cannot be considered apart from the frame to which it is supplying blood.

G. Anæmia.

Anæmia in rheumatism affords valuable evidence of the virulence of an attack. There are few more striking clinical signs than the ghastly greenish pallor of a deadly carditis.

I have always attached much importance to this sign both in children and young adults, and my experience has led me to believe that neglect of the treatment of anæmia in young rheumatic adults favours the development of the malignant form of endocarditis which is most liable to make its appearance in early adult life.

H. Fever.

Fever in rheumatism is generally agreed upon as a sign of activity of the process, but there are cases of great obscurity in which fever persists for weeks and yet no definite explanation is forthcoming. When there is active carditis we naturally suppose that there is progress in the lesions, but there are examples of mysterious fever which

seem to leave no indication of their meaning. I mention them here because they greatly perplex us in our arrangements for convalescence, and remind us that in forming a judgement upon this point we must fall back upon the general condition of the patient and not be swayed overmuch by one symptom.

I. Rheumatic Subcutaneous Nodules.

The last manifestation I shall consider here are the rheumatic subcutaneous nodules. Dr. Cheadle long ago properly insisted upon their grave significance as associated with severe cardiac lesions. There are exceptions—rare cases in which nodules are almost the predominant manifestations, and the heart little if at all affected—but these only serve to accentuate the value of the general rule. It would seem that the occurrence of nodules points to lowered power on the part of the cells to destroy the infective agent, and that the friction of exposed areas and of the movements of tendons suffices to enable the micrococci to overcome this lessened resistance and produce local lesions. It must be remembered that these lesions at one time in their life-history contain the infective agents, and also that the same changes may occur in the subcutaneous tissues without producing an actual nodule.

PATHOLOGICAL CHANGES IN RHEUMATISM.

One of the most useful things to be learnt from the rheumatic nodule is the light it throws upon the pathological changes in rheumatism which must now have some consideration. This is not the place for a minute pathological account, but there are some fundamental facts which are a necessity in the study of infective heart disease.

First of all, the human frame resists the infection with great energy; the tissue cells rapidly destroy great numbers of the micrococci. This can be observed most clearly in the tissues from experiment, but when once these have been studied it becomes equally apparent in the human tissues. When the micrococci escape from the blood vessels into connective tissue spaces, the leucocytes and tissue cells rapidly destroy them; the lesions in rheumatism are fundamentally local lesions, a general septicaemia being unusual. The nodule is of such value because it gives a picture of these local changes. The blood vessels are dilated, the connective tissue becomes swollen, leucocytes invade the damaged area in the centre of which are patches of necrosis. A fortunate section of an early nodule cutting through the margin of a necrotic area will show the micrococci. The lesions are so small and necrotic tissue is so sparse that healing often occurs without leaving any trace of the original swelling behind.

If we study the pericardium, the valves, or the joints, we find the same events happening and differing only in their anatomical surroundings, the extent of the areas of infection, and function of the damaged tissues. Wherever there is necrosis there must be scar formation, and wherever there is great virulence there must be great hyperæmia and rupture of fragile vessels with consequent multiple minute hæmorrhages.

Where the tissues involved are secretory in function the exudations that result differ with the virulence—they are sometimes hæmorrhagic, sometimes clear, and sometimes sero-fibrinous. Much difficulty has arisen over the question of pus formation, but this is in reality mostly artificial. The essential question is this: Are we to use pus as a specific term? For example, is the thick yellow fluid from a staphylococcal abscess to be called pus, and no other similar fluid to bear that name? If so, rheumatism is certainly non-purulent. No one, however, uses the term in this restricted sense, but, on the contrary, we speak of pneumococcal pus, of the thin pus of streptococcal infections, and so on. If we use the term thus, as a description of a phase in an infective process, then there is a rheumatic pus, and it is found in advanced cases of rheumatic pericarditis. It is not in nature identical with the fluid of a staphylococcal abscess, for the chemical changes are doubtless different, but it is probably akin to the pus in some cases of pneumococcal pericarditis.

SUMMARY.

Some further pathological details will be given in later articles under the individual cardiac lesions, but here the

essential points in this cardiac infection may be summarized as follows:

1. There is a great resistance by the tissues to the infection.
2. The general toxæmia varies greatly in different cases.
3. The tendency is to multiple focal lesions.

4. Hyperæmia with increased permeability or fragility of the blood capillaries is frequent.
5. There are swelling of connective tissue, cell proliferation, leucocytic infiltration, and necrosis.
6. Scar formation and adhesion follow necrosis.
7. Exudations vary in character with the virulence and nature of the surface involved.

THE USE OF A DIVIDED MATTRESS AND PELVIC ELEVATOR.

By SIR WILLIAM MACAWEN, C.B., M.D.,
GLASGOW.

When we have so many seriously injured men as at present the following adjuncts to our surgical technique may be useful.

There are two simple contrivances which, on suitable occasions, if used together, or separately, will contribute to the comfort of the patients, to the ease of the nurse,

FIG. 1.—Mattress in four pieces.

and will facilitate the work of the surgeon. These are—(1) a mattress divided into four pieces, and (2) a pelvic elevator. They are of use for fractures of the lower limbs, excision of joints, in paraplegias, sacral bedsores, dressing of pelvic wounds, etc.

When fractures are plated the same necessity for rigid fixation of the parts above and below the fracture does not exist; but even here the comfort of the patient will be increased by the use of a divided mattress and elevator.

In cases of fracture of the femur where it is of importance to maintain the fractured bones in rigid apposition, elevation of the patient for cleansing of the back and pelvis and the introduction of the bedpan are seriously disturbing. This is especially so when treating patients placed on ordinary mattresses, as the pelvis has to be raised and lowered on each occasion, and consequently the fractured fragments, when not plated, are apt to be displaced.

DIVIDED MATTRESS.

For the purpose of keeping the pelvis on the same level with the femur a mattress is arranged divided into four pieces, an upper portion measuring 28 in. in length, a lower piece 34 in. in length, and two centre pieces, each measuring 12 in. in length, with a handle at each end (Fig. 1). (The two latter portions may be made in one piece, but this makes a long part, the breadth of the bed,

not so easily handled). The length of top and bottom pieces may vary according to the height of the patient to be provided for.

FIG. 2.—Pelvic elevator.

Quotation from Ward Sister.

"When preparing this mattress for a patient each of the two larger mattress pieces is covered with a separate sheet, and the small portions placed in position uncovered between the two larger ones. The binder, mackintosh, and draw sheet are then placed across the bed to cover the small portions of mattress, and the ends of the sheet, etc., are tucked in on either side underneath the mattress

as in an ordinary bed. When the bedpan is about to be introduced these two centre pieces are withdrawn, one from either side, and the under sheet adjusted."

The pelvis, however, is apt to sink somewhat when the supporting middle pieces are withdrawn, though a skilful nurse can prevent this. In order to prevent this sinking a pelvic elevator is used.

THE PELVIC ELEVATOR.

The pelvic elevator consists of two strong wire uprights,

which form a frame joined at the top by a piece of metal through which a screw passes supporting a cross piece, to which is attached a pelvic band (see Fig. 2).

When in use this elevator is put across the patient at the level of the pelvis, and, when it is used along with a cut mattress, one limb of the elevator rests on the lower segment of the mattress and the other limb on the upper. When not in use the pelvic band is detached and may be left *in situ*, lying flat under the patient.

When required, the pelvic band is attached to the cross bar of the elevator and the screw revolved until the desired

FIG. 3.—Pelvic elevator in position—the weight being now on pelvic band—preparatory to withdrawal of centre pieces of mattress.

elevation of the pelvis is attained (Fig. 3). The weight of the pelvis is transferred to the pelvic band sufficiently to enable the middle portions of the mattress to be withdrawn without disturbing the pelvis. The sacrum may then be washed or the bedpan introduced without movement of the pelvis, and, consequently, without disturbing its relations with the femur. The elevator is so arranged that it may be wrought by the nurse or by the patient. The latter may assist himself while lying supine by elevating or lowering his pelvis, and so adjust the level to suit his convenience (Fig. 4).

Do not overdo the elevation of the pelvis, as an over-enthusiastic nurse might do; just elevate sufficiently to suit.

Such pelvic elevators may be used for many other purposes: For elevating the pelvis during the application of bandages or surgical dressings; washing and cleansing the patient; for the prevention of bedsores and for the dressing of them when they have occurred; for fracture dislocation of spine, paraplegia, and for bedridden persons who have few attendants, especially as many of the patients could thereby assist themselves by working the elevator to any desired extent. The pain or aching in the back so often complained of during the first days after operation, when patients are compelled to lie supine, can be greatly relieved by the pelvic elevator, which can be adjusted and readjusted, raised and lowered as often as required.

It may also be employed as an elevator for any

FIG. 4.—Pelvic elevator sustaining weight of patient; centre piece of mattress withdrawn.

other part of the body, and, with the addition of extra slings, may act as a support for an arm or a leg. When not in use it may be employed as a cage for keeping the weight of the bedclothes from a fractured limb, or as a fracture cradle.

The divided mattress, as illustrated, was introduced by me in the early seventies for patients who had femoral osteotomies performed on them on both limbs at one time, and in whom it was necessary to main-

tain the limbs rigidly in proper relation with the pelvis until ossification was completed. Since then it has been in use for patients with fractures of the femur, and for other injuries and ailments. It has been found of much convenience to the nurse and comfort to the patient.

The pelvic elevator in one form or other has been used by me for a considerable period, but the newer, lighter forms here depicted have been introduced of recent years. One of these, made of wood in forty-eight hours by the mechanic at Mount Stuart Hos-

pital, Lute, has served its purpose very well.

Desiring, however, to get an efficient and cheap mechanism, stout iron rod was used, the superstructure being made of a single rod bent as illustrated, with a joining plate at the top, where the arches meet, through which the elevating screw goes.

Mr. Hilliard carried out the instruction, and, as shown in Fig. 2, he has introduced a modification which occurred to him, and which allows of the collapse of the mechanism for carriage to a distance.

Further Observations

ON

THE HAEMAGGLUTININ REACTION.

WITH SPECIAL REFERENCE TO THE OPERATION OF
BLOOD TRANSFUSION AND TO NEPHRITIS.

BY

C. J. BOND, C.M.G., F.R.C.S., COLONEL A.M.S.,

HONORARY CONSULTING SURGEON, NORTHERN COMMAND; HONORARY
CONSULTING SURGEON TO THE LEICESTER ROYAL INFIRMARY;
MEMBER OF THE MEDICAL RESEARCH COMMITTEE.

IN THE BRITISH MEDICAL JOURNAL of December 8th, 1917, I drew attention to the use of the haemagglutinin reaction as a method of testing the toxicity of different antiseptic reagents to human blood serum.

A further study of the haemagglutinin content of the blood serum in a series of 250 patients when tested with my own washed red corpuscles and those of the sheep has shown:

I.

That different human serums vary very much in their haemagglutinin content when tested with the same standard red cells. This grading of haemagglutinative capacity is independent of the specific power of different serums to agglutinate the red cells of different individuals according as they fall in one or other of the established groups. Individuals whose serums belong to the same agglutinative group differ in haemagglutinative capacity. Some have a very low and some a high capacity for agglutinating the same washed red cells. The result of the serum test has been recorded on the same plan in all cases; thus +++ indicates a high, ++ a moderate,

and + a slight degree of haemagglutinin effect, while — indicates the absence of any reaction. In all cases the macroscopic method was used (see BRITISH MEDICAL JOURNAL, December 8th, 1917).

This means, of course, that incompatibility of donorship in the operation of blood transfusion is also a graded character, and it is therefore desirable, when testing incompatibility, to express not only the presence but the degree of agglutinative reaction. I have also previously shown that 1 part of non-agglutinative to 4 parts of agglutinative serum is sufficient to neutralize haemagglutination *in vitro*, but before applying this fact to the human subject it is desirable to ascertain by experiment on animals whether the same holds good in the living body. But this grading of agglutinative capacity is also important from the biological point of view.

It is supposed that the familial incidence of a haemagglutinative capacity of blood serum in parents and children follows Mendelian laws. It is, however, evident that a character—for example, haemagglutinin content—which varies from zero to a high positivity is much more difficult to handle as a method of testing inheritance than a sharply defined character of more constant value.

II.

But not only does the specific haemagglutinative capacity vary in degree in different serums, it also varies from time to time in the serum of the same patient. This fact is even more important than the first. I mentioned in my earlier communication that there were reasons for thinking that a non-agglutinative serum may become agglutinative in a patient who has passed successfully through a systemic infection. As the result of a study of 140 patients whose serums have been tested against my own red cells before

and after recovery from wound infection, I have records of 13 cases in which, on a subsequent test, some change was detected in the haemagglutinin content of the blood serum. In all cases the change was either from a negative to a positive reaction, or from a low to a high degree of haemagglutinin content. This generally coincided with a healthier condition of the wounds and with improvement in the general health of the patients.

Nephritis.

I have also tested the haemagglutinative capacity of the blood serum against my own red cells and those of the sheep in 50 cases of nephritis. Of these a second examination has been made, after an interval, in 25 cases, and a change in haemagglutinative capacity was observed in 15. In 7 cases a negative was converted into a positive reaction, and in 8 from a lower to a higher haemagglutinin content as far as my own corpuscles were concerned. With the sheep's corpuscles 5 cases showed a change from — to +, and one from a lower to a higher degree of agglutinative capacity. In three cases only was the change in the other direction. In the first of these a ++ was converted into a — reaction with my corpuscles, the action with the sheep's corpuscles remaining the same—namely, negative. In the second the reaction with my corpuscles remained constant, namely, ++, but dropped from a positive to a negative reaction with sheep's cells. In the third case the human cell reaction fell from ++ to +, but with the sheep's cells the reaction rose from + to ++. The two blood examinations were made in nearly all cases at about a month's interval, and most of the patients were improving generally, with a diminution in the amount of albumin in the urine.

The interesting problem arises in these albuminuric cases whether any leakage of haemagglutinin goes on from the kidney along with the leakage of serum-albumin and globulin.

A somewhat extensive examination of the action of these albumin-containing urines on washed red cells failed to show any distinct evidence of haemagglutinative effect. Certain changes, however, occur in the red cells which I regard as initial stages in agglutination, but the reaction does not become complete owing possibly to physical or biochemical factors in the urine. A control experiment in which a known volume of agglutinating serum was diluted with urine in different proportions showed that distinct evidence of agglutination could be obtained in serums diluted up to 1 part in 10 with urine, even after standing for twelve hours. Different samples of healthy urine also vary in the degree to which they destroy the agglutinative capacity of a given serum. This variation in the urine of different individuals to degrade the blood serum is undergoing further investigation, and may possibly provide a test of urinary toxicity.

Patients suffering from albuminuria consequent on nephritis show, on the whole, a lower haemagglutinin content of blood serum than is found in a corresponding group of partly healthy persons. A series of fifty cases of soldiers suffering from nephritis and a series of fifty male patients whose blood was examined for the Wassermann reaction, in many negatively, gave the following results. The cases are arranged in series showing the haemagglutinative strength:

	+++	++	+	—	Total.
Nephritis cases ...	3	16	20	11	50
Wassermann cases...	13	12	22	3	50

If this reduced haemagglutinin content in nephritis cases is considered in conjunction with the rise in haemagglutinin content which takes place as the albuminuria diminishes and the patients recover, we are led to the conclusion that a leakage not only of serum-albumin and globulin but also of haemagglutinin does take place from the kidneys in nephritis. This is important, because if the blood serum is drained of haemagglutinin it may also be drained of other substances of the antibody group, and this loss may be associated with the lessened resistance to infection which is known to exist in these patients.

Conclusion.

In a considerable number of cases under conditions which require further analysis, but which seem to be associated with recovery from albuminuria in the nephritis cases, and successful resistance to general infection in the wound cases, a definite alteration has been found to occur in the blood serum, for the most part in the direction of an increased haemagglutinin content. The bearing of this fact on the problem of blood transfusion now becomes apparent. If the blood serum of a recipient may be at one time compatible with the red cells of a given donor, and at another time may agglutinate those cells, the donor's serum may also, as the result of recovery from infection or other illness, change in the same way.

Cases have been recorded by Major Robertson, Major Lee, and others, in which transfusion of blood from the same donor to the same recipient had no harmful effects on one occasion but was followed by death on a second. I venture to suggest that changes in the haemagglutinin, and probably in the haemolysin, content of the blood serum of the recipient or donor or both occurred in the interval between the two transfusions, which were responsible for the unfortunate result.

GENERAL ANALGESIA BY ORAL ADMINISTRATION.*

BY

CAPTAIN JAMES T. GWATHMEY, M.R.C., U.S. ARMY,

AND

CAPTAIN HOWARD T. KARSNER, M.R.C., U.S. ARMY.

This report is in the nature of a preliminary communication based on animal experiments and a sufficient number of clinical cases to support the conclusions of the animal work. It will be seen that general analgesia in which there is loss of sensation, with or without loss of consciousness, can be established for otherwise painful dressings and for short operations. The desirability of such a procedure becomes apparent immediately on entering a military hospital, and it has also a definite place in civil surgery.

Many war wounds are accompanied by fractures of bones, and the importance of keeping such patients quiet is universally recognized. If the dressing of such a wound is accompanied by severe pain, it is customary at this base to produce nitrous oxide-oxygen or light ether anaesthesia for at least the first few dressings, necessitating in most cases, because of limitation of apparatus, removal of the patient to the operating room. This usually means pain and the danger of misplacing the bone fragments before and after dressings, as well as loss of time to surgeons, nurses, and orderlies. General analgesia, produced simply and quietly without taking the patient from his bed, is the logical solution of this difficulty, and the technique evolved as the result of this study makes it possible to administer the analgesic by mouth in perfect safety. It is, of course, applicable to practically all forms of painful dressings, and is being developed to embrace short surgical operations, such as resection of a rib, removal of foreign bodies, revision of wounds. In such operations, however, it may be necessary to supplement the analgesia with novocain for the skin incisions, a hypodermic injection of morphine, or even by light inhalation anaesthesia.

Local conditions made it seem advisable to select rabbits as the animals for the preliminary work. The animals were tied to a board and the various substances given by stomach tube, after which the animals were immediately released and placed under observation.

Quinine and Urea Hydrochloride (Nikalgin):

Weight of Animal.	Amount.	Result.
2200 gm. ...	4 c.cm. }	No systemic effect.
2105 " ...	8 c.cm. }	
2250 " ...	16 c.cm. }	
1795 " ...	30 c.cm. }	
2215 " ...	60 c.cm. }	Unable to stand after 10 minutes and died in 8 to 17 hours.

* Aided by grants from the American Red Cross.

Trional (dissolves in alcohol, 1 grain to 1.5 c.cm.):

Weight of Animal.	Amount.	Result.
2230 gm. ...	1 grain	Reflexes active.
2470	3 grains	Reflexes abolished in 1 hour; still on feet.
2175	6 grains	Reflexes abolished in 45 minutes, remaining so for 5½ hours; full recovery in 8 hours.
2460	9 c.cm. alcohol (control)	Reflexes partly abolished.

Morphine Tartrate (in water):

1810 gm. ...	½ grain	No appreciable effect.
2560	2 grains	
2000	3 ..	
2050	4 ..	

Paraldehyde:

1710 gm. ...	2 c.cm. ...	Dropped in 15 minutes, slept 4 hours; not analgesic.
2220	4 c.cm. ...	Dropped in 15 minutes; analgesic 6 hours; complete recovery.
	6 c.cm. ...	Died in 15 hours.

Ether in Olive Oil, 50 per cent.:

2430 gm. ...	5 c.cm. ...	Reflexes only partially inhibited, never off feet.
2170	15 c.cm. ...	Reflexes partially inhibited.
2420	30 c.cm. ...	Reflexes completely abolished; apparently full recovery. On repeating dose next day, animal died in 30 minutes. Necropsy showed dilated stomach, with congestion, erosion, and sub-mucous petechiae.
2050 gm. ...	20 c.cm. ...	Reflexes abolished in 6 minutes; apparently complete recovery in 1 hour 16 minutes. Killed after 24 hours, and necropsy showed same findings as in preceding animal.
2095 gm. ...	25 c.cm. ...	Reflexes abolished in 5 minutes; apparently complete recovery in two hours. Killed after 24 hours, with same result as in preceding animal.
—	30 c.cm. olive oil without ether	No effect. Killed after 24 hours, and showed same condition in stomach as preceding animals.

Ether in Olive Oil, 25 per cent.:

Animal.	Amount.	Result.
No. 1 ...	30 c.cm. ...	Down in 12 minutes; reflexes not abolished.
No. 2 ...	20 c.cm. ...	Inco-ordinate.
No. 3 ...	10 c.cm. ...	No apparent effect.

All three animals were killed after twenty-four hours; stomach not dilated, fridus much congested and covered with much adherent mucus.

Paraldehyde plus 25 per cent. Ether in Olive Oil:

Weight of Animal.	Amount.	Result.
2100 gm. ...	1 c.cm. paraldehyde	No effect.
1880	10 c.cm. ether in olive oil	Down in 5 minutes; reflexes partially inhibited; practically restored in 10 minutes. Recovery in 25 minutes.
2170	Combination of above	Down in 5 minutes. Reflexes practically abolished in 10 minutes. Recovery in 30 minutes.
1950	Paraldehyde 2 c.cm. and 25% ether in olive oil 20 c.cm.	Down in 5 minutes; slept for nearly 2 hours.
2060	25% ether in olive oil 20 c.cm.	Down in 5 minutes; slept for 1 hour.

Other Combinations:

Weight of Animal.	Amount.	Result.
2000 gm. ...	Morphine tartrate 1 grain	All inco-ordinate, but no other effect.
	Ether ... 2.5 c.cm.	
	Albolene ... 7.5 c.cm.	
1965 gm. ...	Morphine tartrate 1 grain	
	Paraldehyde 1 c.cm.	
	Albolene ... 2 c.cm.	
2110 gm. ...	Paraldehyde 1 c.cm.	
	Ether ... 3.75 c.cm.	
	Albolene ... 11.25 c.cm.	

These experiments were not conducted as experiments on the detailed physiology of analgesia, but simply for the purpose of demonstrating that analgesia can be produced by oral administration of proper agents. As will be seen, various combinations of drugs were not especially successful, and in rabbits the best results were obtained by the use of ether in oil. It was found, however, that this mixture produced acute gastritis in the animals, but further investigation showed that olive oil alone produced quite as severe a gastritis as when combined with ether. Knowing that olive oil is practically non-irritant to the human stomach, it was considered safe to proceed with the investigation on man. It was thought, however, that some mineral oils might be even less irritant in man, and accordingly the menstruum was changed to either liquid paraffin (albolene)

or Russian mineral oil. The fact that there are said to be ether drinkers in Ireland and France who apparently suffer no more than alcoholics, made it seem additionally safe to try the mixture of the two for clinical work. Additional support was drawn from the fact that in many hospitals ether is being applied as a local dressing without deleterious results. Finally, a 65 per cent. solution of ether in oil has been used in many thousands of cases of oil ether colonic anaesthesia without any sign of local irritation to rectum or colon, as has been proven by proctologic examination, as well as by the fact that no case of dysentery or bloody diarrhoea has been observed.

Clinical Data.

The following combinations have been tried clinically:

I. Ether
Liquid paraffin
Aq. menth. pip.
II. Paraldehyde
50 per cent. ether in albolene
Aq. menth. pip.
III. Ether
Albolene
Aq. menth. pip.

The mixtures containing paraldehyde were disagreeable to the taste and smell, the ether oil very much less so, but the difficulty was soon overcome by following a suggestion by Major W. E. Lower. One ounce of port wine is placed in a glass and the analgesic in another glass. The patient takes a mouthful of wine, holds it for about thirty seconds, rinsing the mouth so as to get the aroma in the upper air passages and the taste well established, and then swallows the wine. The ether mixture is then taken and is followed immediately by the remainder of the wine. Several wines and liqueurs were tried but port wine was found to be the most satisfactory. One of us (J. T. G.) and several other physicians have taken this "Lower sandwich," and have found it not disagreeable and to produce analgesia. As will be seen from the following notes, numerous patients have been given it with excellent results. Only one patient has been nauseated, a man who was violently opposed to taking the wine. As opposed to that case it was given to another man, who had repeated attacks of vomiting, immediately after an attack. His dressing was done without pain, and his vomiting ceased permanently. All the cases have been able to take food and water shortly afterward, and even in patients much exhausted by infection there have been no deleterious after-effects. It was soon found that the paraldehyde served no useful purpose, and most of the dressings have been done with Formula I. While it is well not to give the analgesic immediately after a meal, no especial preparation of the stomach is necessary.

Under the general direction of Major W. E. Lower, the following cases were dressed in No. — (Lakeside, U.S.A.) General Hospital, American and British Expeditionary Forces, by Lieutenants B. I. Harrison and W. R. Barney. All the dressings were done without removing the patient from the ward.

CASE I.

Soldier, aged 36. Gunshot wound of right thigh, and infected compound comminuted fracture of femur. Previous dressings had been very painful, and the splint could not be changed without general inhalation anaesthesia. Given: Paraldehyde fl3 j, ether fl3 iij, liquid paraffin q.s. ad fl3 j. In fifteen minutes fell into a light sleep. The wound was dressed, splint removed, through-and-through wound irrigated with ether, gauze drain inserted down to femur, and Thomas splint applied with extension. The patient talked during the dressing, felt practically no pain, and suffered no nausea or other ill after-effects. The dressing was repeated in a similar manner every other day for four dressings, and in none of them was there pain or any alteration of pulse or respiration.

CASE II.

Soldier, aged 28. Gunshot wound of left thigh, with compound comminuted fracture of femur. He was given same mixture as Case I, and fell asleep after twelve minutes. The Thomas splint was removed and replaced, gauze packing removed, wound irrigated with ether, and another gauze pack reinserted. The patient groaned when the pack was reinserted, but after regaining complete consciousness said that he had felt no pain during the dressing. Three subsequent dressings were done on alternate days with no nausea or other after-effects, nor alteration of pulse or respiration. The patient complained of the taste of the mixture, but said it was far to be preferred to the extreme pain of the dressings.

CASE III.

Soldier, aged 23. Gunshot wound of left leg—compound comminuted fracture tibia and fibula; through-and-through infected wound. He was given the same mixture as Case I, fell asleep after fifteen minutes and slept for thirty minutes, during which the dressings were done. Thomas splint repadded, packing removed and reinserted; ether irrigation. Two dressings were done without ill after-effects.

CASE IV.

Soldier, aged 39. Gunshot wound of left thigh, through-and-through, with compound comminuted fracture of head of femur. All previous dressings extremely painful. Given paraldehyde H_5ij , ether, alcohol, $\text{an } \text{H}_5\text{ij}$. Wound cleansed, packing removed and reinserted. The patient groaned at one time, but had no later recollection of having had pain. The pulse increased from 108 to 110 and respirations from 26 to 28. No nausea. Three subsequent dressings on alternate days were equally painless and without ill after-effect.

CASE V.

Soldier, aged 23. Gunshot wound of right leg, infected; compound comminuted fracture of tibia. Dressings very painful. He was given same mixture as Case I; dressing done with much less pain than before; the pulse rose from 100 to 116, and respiration from 24 to 26. A few days later the dose was repeated, and the patient slept through the dressing. No ill after-effects.

CASE VI.

Soldier, aged 27. Gunshot wound of thigh; streptococcus infection. No fracture. Given morphine tartrate gr. $\frac{1}{2}$, ether H_5ij , alcohol H_5ij , paraldehyde H_5ij . Multiple superficial incisions were made for drainage with very slight pain, probably because of dressing following too soon after administration of mixture. The pulse rose from 110 to 120. The patient was vomiting before the mixture was given, but retained it and did not vomit afterwards.

Several other dressings are briefly summarized in the accompanying table.

Following the above experiments, one of us (J. T. G.) was ordered to a casualty clearing station. The following cases from the service of Captain D. C. Taylor, R.A.M.C., illustrate some of the possibilities of the method:

Two almost parallel cases of penetrating wounds of the knee occurred on November 15th. Case I was given the usual inhalation ether anaesthesia with the Slipway apparatus; Case II was given 1 oz. of 50 per cent. ether in liquid paraffin. Thirty minutes later a supplementary 2 drachms of chloroform were given by inhalation during the operation. The knee-joint was opened, pieces of comminuted patella removed, the joint irrigated with saline and closed. Both cases rested quietly for one hour after operation. Case I then complained, and required a hypodermic injection of morphine for the control of restlessness and pain. About the same time Case II awakened, drank some milk, and fell asleep again. Both patients slept until breakfast time. Case I drank some tea, but refused other food. Case II had tea, porridge, and bread-and-butter. Neither vomited afterwards, and both were evacuated to a base hospital in about four hours.

Two other cases of Captain Taylor's were given each a double dose of the mixture (2 oz. 50 per cent. ether in liquid paraffin). Each required only a few additional drops of inhalation anaesthesia. The resultant analgesia after operation was a little more prolonged than with inhalation anaesthesia. One of these patients was ready for operation in ninety seconds, and required 1 drachm of chloroform, given drop by drop, to "carry on" an operation lasting thirty minutes.

The substitution of chloroform for paraldehyde has been found to make even a more satisfactory mixture than the

preceding. The following formula has been used in approximately thirty cases:

Chloroform	$\text{H}_5\text{ss to j}$
Ether	$\text{an } \text{H}_5\text{ijss}$
Liquid paraffin	

It is not recommended at the present time to exceed this. It is our opinion that the toxic effect of this small amount of chloroform can be disregarded in military surgery.

Discussion.

The physiology of "general analgesia" by oral administration has not been subjected to an exhaustive investigation, but certain important facts should be borne in mind by those who contemplate using the method outlined. The oil and ether mix perfectly, and do not separate into layers. Baskerville has shown the rate of evaporation from minute to minute to be constant, so as to form a straight oblique line when plotted out. This holds true with different percentages of ether in the oil, in all cases assuming a constant temperature and exposed surface. It is therefore impossible for the patient to get an overdose at one time and an insufficient amount at another time. The total amount is not absorbed at one time; if it were, the administration of 2 ounces of 50 per cent. ether in oil would produce complete anaesthesia, as there would be liberated 1 ounce of ether. Only a light analgesia is obtained which, for operative procedures, must usually be supplemented in some way. Naturally, the surface for evaporation is greater in the stomach than is the case in the colonic method, and the absorption of ether more rapid. The total amount that may be given with safety by this method has not yet been determined. It is considered advisable for the present to supplement the method either by local anaesthesia or the administration of small amounts of anaesthetic by inhalation. But it is important to remember that the patient is as safe by this method as if the ether were in a container outside the body. All anaesthetics are analgesics, and before the danger zone is reached the patient must become anaesthetized; hence the patient in the analgesic stage is separated from the danger zone by the period of anaesthesia. We consider analgesia by this method as safer than any method of anaesthesia. If the anaesthetist carries his patient to the "blear-eyed" snoring stage, he defeats the object for which this special method was devised, the object being to take advantage of the analgesic stage of any and all anaesthetics used. If adopted it would release from the routine of administration of anaesthetics a certain number of physicians who now, in military hospitals, devote their entire time to that work.

CONCLUSIONS.

It is felt that in so far as one can do so in a preliminary communication of this sort the following conclusions are justified:

1. General analgesia is safer than general anaesthesia.
2. Fifty per cent. ether in liquid paraffin or other bland oil is probably the safest general analgesic, has apparently no deleterious effect upon the stomach, and is not followed by the nausea and vomiting that frequently accompany inhalation anaesthesia. Its effect may be enhanced by the addition of a small amount of chloroform ($\text{H}_5\text{ss to j}$). It may be given without unpleasant taste when "sandwiched" between mouthfuls of port wine.
3. The method is especially indicated during the dressing of painful wounds without taking the patient from his bed.

Nature of Dressing.	Admini- stration.	Time of Dressing.	Result.	Pulse.	Respiration.	Pupils.	After-effects.

or ward, and, when supplemented, can be employed for surgical operations.

Note.—Our thanks are due to the medical director and members of the staff of No. — (Lakeside, U.S.A.) General Hospital, who have co-operated in this work. Major Alexander Lambert, Medical Director of the American Red Cross in France, on whose personal staff one of us (J. T. G.) had the pleasure of serving, has in many ways stimulated the working on this problem, and we take pleasure in expressing our warm appreciation of his interest and help.

THE EFFECT OF A DEEP HELD INSPIRATION ON THE MURMUR OF SLIGHT AORTIC REGURGITATION IN YOUNG SUBJECTS.

By W. GORDON, M.A., M.D.CANTAB., F.R.C.P.LOND.,

PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL;
MEDICAL OFFICER IN CHARGE No. 1 SECTION
EXETER WAR HOSPITALS.

I wish to draw attention to what I believe to be an undescribed clinical phenomenon—namely, the marked diminution or complete disappearance of the diastolic murmur of aortic regurgitation (in young subjects with only slight regurgitation) when a deep breath is taken and held.

The well recognized disappearance of a systolic murmur at or near the heart's apex under similar conditions has often been regarded as evidence in favour of such a murmur being exocardial—"cardio-pulmonary" as it has been called—rather than endocardial. Certainly some murmurs, reasonably diagnosed as "cardio-pulmonary," because most audible over areas in which lung tissue overlaps the heart, varying obviously in intensity with the phases of respiration, ceasing in recumbency, not following the usual rules of "conduction" of mitral murmurs, although heard at or near the heart's apex, do disappear when a deep breath is taken and held. But recently I have been led to wonder whether other murmurs, due to real mitral lesions, may not also disappear in similar fashion. Of such I cannot now speak with any confidence, but it is at least interesting to discover that an actual organic murmur like that of aortic regurgitation may also lessen or vanish during deep sustained inspiration. The three following cases have all been seen, and my conclusions verified, by valued colleagues, so that the truth of my observations does not rest on my own unsupported statements.

CASE I.

Pte. G., aged 19, had a well-marked aortic regurgitant murmur

FIG. 1.—M, Approximate area of audibility of murmur—straight line, standing; dotted line, recumbent. o, Position of stethoscope during observations.

was rather diffuse. The limits of the cardiac dullness were:

Standing.	Recumbent
Right edge: 1 in. to R. of midline	2 in. to R. of midline.
Left edge: 4½ in. to L. of midline	4½ in. to L. of midline.

There was no other murmur in any position. Curiously, the weather seemed to make a difference in the effects of inspiration, as I note below. On December 30th, during very cold weather, I noticed that the murmur was almost obliterated when the patient took and held a very deep breath, whether examined in the erect or recumbent position. On expiration the murmur returned. On December 31st, the weather being warm and mild, the deep held breath entirely obliterated the murmur. On January 1st, a warm day, the murmur at the sternal junction of the fourth left rib cartilage was entirely lost on taking and holding a deep breath; in recumbency a sharp reduplicated second sound remained. On January 9th, a warm

day, the murmur was quite lost in the erect position, but not quite lost in the recumbent position, when the deep breath was taken and held.

CASE II.

Driver W., aged 26, admitted August 19th, 1917, with slight aortic regurgitation, and slight double mitral murmur. Fig. 2 shows approximately the area of audibility of the aortic murmur. There was no doubt of the nature of the murmur, there being no murmur heard over or to the left of the pulmonary artery. The lesion was slight, judging by the almost complete absence of pulsation in the neck and the character of the radial pulse.

The diastolic murmur quite disappeared on taking and holding a very deep breath in the erect position, and nearly disappeared in the recumbent position.

FIG. 2.—M, Approximate area of audibility of murmur, standing. c, Cardiac dullness, standing. o, Position of stethoscope during observations.

CASE III.

Pte. R., aged 20, admitted November 18th, 1917. I found presystolic and systolic mitral and a soft diastolic aortic murmur. The pulse was not water-hammer, and there was no pulsation to the ear in the neck.

On taking and holding a deep breath the diastolic murmur diminished distinctly, not immediately but by degrees, and, on releasing the breath, returned, but more quickly. I believe the same gradual disappearance of the murmur occurred in the other cases also. On November 25th, at the level of the fourth left costal cartilage (showery stormy day) the diastolic murmur quite disappeared on holding a deep breath. On December 1st it quite disappeared, equally in erect and recumbent positions. The condition is illustrated in Fig. 3.

FIG. 3.—c, Cardiac dullness, standing. o, Position of stethoscope during observations.

Case I was seen by my colleagues, Dr. Clapp and Dr. Gates; Case II by Dr. Williamson and Dr. Gates; Case III by Dr. Williamson and Dr. Gates.

With regard to possible explanations, mere extra overlapping with lung could not have concealed the murmur, for the second sound, which preceded it, remained quite clear. My idea has been that perhaps the negative pressure set up in the thorax by the deep inspiration partly neutralized the elastic recoil of the aorta, thus lessening the force producing the regurgitation; and that, further, seeing that the effect developed not at once but gradually, the increased volume of the pulmonary capillaries in deep inspiration delayed the entry of blood into the left side of the heart, and produced a rather less full aorta. If these theories are correct they will help to explain the influence (if real) of weather, since on a cold day the aortic tension may perhaps be higher, owing to constriction of surface vessels, than on a warmer day.

It is, however, not to this attempt at explanation, but to the phenomenon itself, that I desire to draw attention.

THE CONSERVATIVE SURGERY OF THE HAND AS ILLUSTRATED BY A CASE OF TENDON GRAFTING.

BY

COLONEL A. W. MAYO-ROBSON, A.M.S., C.V.O., C.B.,
D.S.C., F.R.C.S.,

CONSULTING SURGEON, SOUTHERN COMMAND.

It will readily be granted that although the work of the instrument maker in making artificial limbs is excellent, nothing yet invented can take the place of the human hand or even of a thumb and one or more fingers. There are at the present time many cases coming before surgeons doing military work in which the possibility of saving even one finger has to be seriously considered.

The purpose of this paper is to show the possibility of tendon grafting, which I think must have escaped the memory of orthopaedic surgeons, as I have not seen it made use of in any of the hospitals I have inspected

during the war. On May 24th, 1889, I read a paper on the subject before the Clinical Society of London and at the same time showed a successful case. In a leaderette in the BRITISH MEDICAL JOURNAL for June 1st, 1889, occurs the following statement:

Among the papers read last Friday, at the Clinical Society was one which chronicles another advance in conservative surgery, showing that another tissue of the body (tendon) can be successfully grafted as skin, bone, and nerve have been.

The following is a history of the case referred to:

I was asked in November, 1888, to see J. L., a weaver, aged 32, with a view to amputating his right arm for an injury caused by machinery.

The whole of the inner side of the forearm up to the elbow was hopelessly crushed and lacerated, exposing the ulna from one end to the other, but not opening the elbow-joint. The muscles were torn and the bone was rasped bare of periosteum. The wrist-joint was opened and the inner row of carpal bones was crushed. The three inner fingers were hopelessly smashed and the whole dorsum of the hand was swept clean of skin and tendons except the extensors of the thumb, which were bare but not otherwise damaged.

The index finger, excepting that its metacarpo-carpal joint was opened and that its extensor tendons had been completely torn away, was not further injured. After a little consideration, I decided to try to save the radius, the radial half of the carpus, and the thumb and index finger, and, in order to give the possibility of a useful index, to make an extensor indicis from the flexor tendon of the smashed middle finger.

The whole limb was scrubbed with soap and carbolized water, well rubbed with benzol and then thoroughly washed with 1 in 1,000 perchloride of mercury solution.

As the skin of the inner side of the forearm was destroyed and the bone injured, the ulna was excised to within a short distance of the elbow. The inner side of the carpus was removed, together with the three inner fingers, the skin of their palmar aspects being saved to lap over and cover the dorsum of the hand. The flexor tendon of the middle finger was taken out of the sheath, and four and a half inches of it detached and placed over the site of the extensor indicis, the proximal end of the tendon being stitched to the fleshy belly of the extensor communis digitorum, the distal end being fixed to the small portion of tendon left near its insertion into the phalanx. The skin was brought over to cover as nearly as possible. No drainage was employed. The wounds pursued an aseptic course, and there was no sloughing of tendon or skin. The patient returned home within a month, and was advised to try to use his finger and thumb.

He returned to his work in February, and when shown to the members of the Clinical Society he said he could perform his work as a weaver as well as ever. The movements of the fingers were very good, both in flexion and extension; the wrist-joint was movable, and both pronation and supination could be effected. During extension of the index finger the new tendon could be felt to move freely under the integument of the dorsum of the hand.

The man expressed himself as perfectly satisfied with his hand, which enabled him to earn his living as well as ever he could.

My apology for bringing to light this work after thirty years is that I venture to think an unsightly hand with a thumb and a finger is much better than any artificial limb, however perfect it may be.

ACUTE INTESTINAL OBSTRUCTION DUE TO JACKSON'S MEMBRANE.

BY

FREDERICK C. PYBUS, M.S., F.R.C.S.,

SURGEON TO THE HOSPITAL FOR SICK CHILDREN, ASSISTANT SURGEON TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE.

It has been doubted by some whether the membrane covering the proximal portion of the ascending colon causes obstruction to the passage of the intestinal contents. It has been my belief that such was the case, and that to this might be ascribed the symptoms associated with this condition. In cases where the pericolicitis (so called) manifests itself as a filmy membrane little or no obstruction can be demonstrated on examination of the colon. Where, however, the Jacksonian membrane is associated with fibrous bands crossing the colon, varying degrees of constriction may be noted. It is possible that this partial obstruction may also account for the dilatation and elongation of the caecum associated with such cases. The clinical symptoms would also suggest this, for the colicky pain, occasional vomiting, gurgling over the caecum, and tenderness on pressure, point to a temporary obstruction. This syndrome forms a common type of dyspepsia

which can be recognized, but which too frequently, even now, is regarded as appendicitis and for which simple appendectomy is performed. That such a band can cause greatly exaggerated symptoms and result in acute intestinal obstruction the details of the following case show. I believe it an uncommon type of acute obstruction and so venture to place the case on record.

Mrs. S., aged 41, was admitted to the Royal Victoria Infirmary on January 18th, 1916, with symptoms of acute intestinal obstruction.

History.

For some years she had had attacks of abdominal pain and also marked constipation, the bowels only moving after an aperient. Three weeks before admission the pains had become worse, she vomited occasionally and had increased difficulty in getting the bowels open. For a week the pain had been severe, vomiting incessant and there had been no action of the bowels, while flatus had not been passed for three days. She had passed blood and slime by the rectum during the last three weeks.

On admission the temperature was 99.8°. The patient looked ill, and although fairly well nourished had a sallow complexion and had few teeth left. The abdomen was moderately distended, a distinct tumour being visible in the left iliac fossa. This tumour was composed of distended intestine; peristalsis could be seen and felt, while borborygmi could be heard during the contraction of the intestine, which caused the patient evident pain. Rectal examination was negative. A diagnosis was made of chronic intestinal obstruction become acute due probably to carcinoma of the pelvic colon.

First Operation.

On January 18th, 1916, the abdomen was opened in the left iliac fossa. Free fluid escaped on opening the peritoneum. A tense cyst was found occupying the left iliac fossa and extending to the bottom of the pelvis. The swelling had the appearance of a thin-walled ovarian cyst, but was tympanitic, and the taenia coli at once distinguished it as the caecum. No part of it could be drawn out of the wound, so it was punctured and a Paul's tube tied in. After evacuating part of its contents the caecum was sutured to the margin of the incision.

The patient improved greatly after the operation. The distension subsided and the bowels were moved normally on several occasions.

Second Operation.

On February 2nd, 1916, the abdomen was opened in the middle line below the umbilicus. The collapsed caecum was found crossing the abdomen from the right side to the caecostomy opening in the left iliac fossa. The lower part of the ascending colon was mobile and was covered by a thin membrane, at the upper border of which was a tight band passing from the parietal peritoneum to the inner border of the colon. The band was the thickness of a match stalk, it tightly puckered the ascending colon, and it was with difficulty that two fingers could be inserted beneath it. The band was removed and part of the membrane stripped away. The caecostomy opening was dissected free from the skin and closed, the caecum being returned to the abdomen, which was then closed. The appendix was normal and no trace of inflammatory adhesions were present.

After-History.

The patient was discharged from the hospital, well, on February 17th, 1916.

In November, 1916, the patient remained in good health, though she still had to take opening medicine.

On two occasions, in August and October, 1916, she had attacks of abdominal pain and vomiting, which necessitated her staying in bed for a few days. Should these attacks persist, further treatment of caecostomy or short-circuiting may become necessary.

REDUCTION EN MASSE OF A STRANGULATED DIRECT INGUINAL HERNIA.

BY

H. H. RAYNER, M.B., B.Ch. (Vict.), F.R.C.S. (Eng.),

CAPTAIN R.A.M.C.T.,

HONORARY ASSISTANT SURGEON, MANCHESTER ROYAL INFIRMARY;
VISITING SURGEON TO THE MANCHESTER CHILDREN'S HOSPITAL.

This case impressed me as a remarkable one in several respects, and I venture to think that it should not be allowed to drift into one's personal experience without a record.

Early in September, 1917, I was asked by Dr. Taggart, of Heaton Moor, Stockport, to see a lady who three days previously had begun suddenly to have pain in the abdomen and right groin; a few minutes afterwards she vomited several times, and noticed a lump in the right groin; she had never previously suffered from hernia.

Dr. Taggart saw her some two hours after the onset and found a tense rounded swelling in the right inguinal canal, about the size of a Tangerine orange, which did not yield an impulse on coughing; the swelling was clearly a strangulated hernia, and

with gentle manipulation it was easily reduced. Dr. Taggart was struck by the fact that the reduction was sudden and complete, giving him an impression like that of pushing a button through a buttonhole. The patient felt relieved for a time, but during the night and next day she was uncomfortable and had occasional attacks of slight colic, and vomited twice; the following day (the third) she still complained of occasional abdominal pains, and again vomited twice.

During the time between the reduction of the hernia and my seeing her the patient had not been given any opium or sedative because the pain was not severe; the bowels had not been moved, nor had she passed flatus, except in small amounts, despite enemata; very wisely, no purgative medicine had been permitted.

Her condition when I saw her on the fourth day of her illness was as follows: A well-developed woman, spinster, aged 45; her general condition and appearance was good. Temperature normal, pulse 92. Abdomen slightly distended, but showing no visible evidence of peristalsis during observation over several minutes. When handling the abdomen, splashing sounds could be heard, and I got the impression of feeling distended coils of intestine. The hernial orifices were normal, and a pelvic examination did not yield any evidence.

Operation.

Laparotomy, some hours later, through the right pararectal incision disclosed a loop of small intestine, 4 in. in length and about three feet above the ileo-caecal junction, tightly strangulated in a peritoneal pouch; the origin of the pouch was not at first clear, but it proved to be a direct inguinal sac displaced from the inguinal canal into the abdominal cavity. By dividing the orifice of the sac the loop of strangled intestine was easily released; at its point of entrance into the sac the loop showed a narrow annular strip of gangrene; it was simply covered over by an invaginating suture.

After suture of the peritoneum and muscles, the right inguinal canal was exposed, the sac pulled out into the canal and its relations as a direct (external direct) hernia clearly established. The sac was removed and the canal obliterated.

The patient left the nursing home within three weeks, and is now in good health and leading a normal life.

The noteworthy features of this case, apart from the reduction *en masse*, were:

1. The rarity of true direct inguinal hernia in the female.
2. The infrequency of strangulation of a direct inguinal hernia. Given strangulation of such a hernia, it is probable on anatomical grounds that reduction *en masse* is more likely to occur than in the case of the ordinary oblique type.
3. The subacute—in fact, quiet—character of the symptoms of obstruction which the patient presented considering the severity of the lesion; this I ascribed to the deliberate abstention from any aperient medicine and the restriction of her nourishment to the plainest fluids.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A HELPFUL DIAGNOSTIC SIGN IN RUPTURED DIGESTIVE ULCERS.

MR. WILLAN'S article in the JOURNAL of February 2nd is of great interest, and he is to be congratulated on his masterful description of the condition. The tight constricting band at the level of the lower ribs, the vertical obtuse angle, and the rigidity, present a complex diagnostic sign of great value. I believe it will be found of real use in some cases of subphrenic abscess, and will help in the diagnosis of this condition, which almost always is attended with difficulties.

A few weeks before Mr. Willan's description appeared, a patient admitted to the Cheltenham General Hospital presented this sign in a very marked degree. I will not enter into detail, but will be content to state that at the *post-mortem* examination, eleven days later, dense adhesions were present in the upper abdomen, with pus. An ulcer of the stomach had perforated, not in the usual acute way, and nature was attempting to shut off the diseased area. There is good reason to believe that adhesions were present before the last catastrophe, which did not present itself as an acute emergency.

I do not think the sign is present in a marked degree, if at all, in most cases of acute perforation, for the picture is so marked, when present, that it would have been described long ago.

It is one of those "pathognomonic" signs to which, nowadays, too little value is attached in the art of diagnosis. The present tendency to confine the diagnosis of abdominal

conditions to whether or no the abdomen should be opened, and to complete the diagnosis afterwards, is woful. The great majority of abdominal conditions, acute and chronic, can be correctly diagnosed after an average experience by the use of common sense. The sign Mr. Willan has described will form part of the armament of the thoughtful diagnostician.

Cheltenham.

S. M. HEBBLETHWAITE.

PREVENTION OF WATER-BORNE DISEASE IN THE TRENCHES.

A TYPE of water-borne diarrhoea observed in the winter in Belgian trenches was characterized by a tongue generally clean or moderately furred, and by marked temporary intractability to either sedatives or purgatives. Its course was rather under a week, as a rule, without fever, or with a temperature under 100°, without blood in the stools, but with very considerable pain and tenesmus. It could be clearly distinguished from the diarrhoeal form of trench fever by the tongue, which in that disease, as I have previously described, has a clean margin a quarter of an inch broad, and later by the lack of pain other than abdominal, and by the temperature chart. The incubation period was eight days. A prophecy made after some experience, to the effect that diarrhoea would break out at the end of the period as a result of a movement of the water-carts which was not communicated to the company officers, was accurate to the day, when some half-dozen cases appeared though the battalion had been free from this disease for a considerable period. The special methods of prophylaxis adopted may, in view of the ubiquity of water-borne diseases in all armies in greater or less degree, be of some interest.

1. The use of chlorinated water is all-essential. The statement that "the water is always boiled before use" is certainly not true as far as the preparation in the trenches of many a stew and many a dixie of tea is concerned.

2. The discipline of the company commander must be such that his orders that no water is to be taken except from the water-cart must be obeyed to the letter.

3. The water corporal must keep a record of every gallon supplied from the cart, and to whom it is supplied. It is best to take the name of each man and the platoon or section which he supplies, and, in the case of isolated strong points, the names of the men he supplies. The amount of water taken per company is compared with the trench strength of the company, and from this the number of pints per man is obtained. By obtaining the amount of water used by the cooks for stews, tea, etc., by observing the tempting streams crossing the routes of weary water carriers and the efficiency of water guards, if any, set over them, remarkably accurate deductions can be made as to the source of some or all of the water used. To obtain the records the water men must work on double shifts; water, at all times, if possible, should be available for the carriers as they arrive, or, at any rate, the sergeant-major warned daily as to the exact hours at which it is available. The labour of carrying adequate supplies up the trenches is very great, yet the importance of this is obvious.

It was observed in one instance that the surface water derived from an area within the trenches was apparently as pure as that derived from the tanks miles behind, requiring less than a single measure of chloride of lime. By bacteriological examination and by repeated daily examination with the Horrocks cabinet, it is possible under certain geological and other conditions that a very large amount of labour could be saved by a battalion in the line.

It is hoped that the simple methods here described might, under conditions where it is feasible to supply water at all in the trenches, go far practically to eradicate water-borne disease from an army fighting under modern conditions.

E. R. GRIEVESON, M.B., Ch.B. Edin.

THE United States War Department has decided to extend the system of psychological examinations to all enlisted men and newly commissioned officers. Specially equipped buildings will be provided in each army cantonment, and a school of military psychology established at Fort Oglethorpe, Georgia. The object of the tests is to help in weeding out the mentally incompetent and classifying men according to their mental capacity.

Reports of Societies.

AUTOLOGOUS GRAFTING IN MALIGNANT AND NON-MALIGNANT CONDITIONS.

In a paper read at the meeting of the Pathological Section of the Royal Society of Medicine on February 19th, when Dr. WILLIAM BULLOCK, F.R.S., President, was in the chair, Dr. J. A. MURRAY said that the results of the long series of auto-transplantations made by Haaland had been confirmed by Apolant, F. C. Wood, and himself, and it might safely be said that there was no type of undoubted malignant new growth in which auto-transplantation had not been successful; consequently, in all investigations necessitating the most rigorous demonstration of the malignant nature of new growths, auto-transplantation should be included in the tests applied. His paper dealt with an attempt to apply this test to the discrimination of an ill-defined group of new growths, namely, those of lymph nodes—lymphomata. A great variety of growth-like enlargements of lymph nodes occurred in the mouse, and might affect any one of the three component tissues to the exclusion of the others. For the present the new growths of the endothelium and of the reticulum had been ignored, and attention restricted to those arising from the lymphocytes and their mother cells in the germinal centres. In a tissue which subserved the cellular reactions of the body to extraneous agencies, a considerable degree of proliferation with increase in size might occur and present all the appearances of a progressive proliferation. The ease with which the lymphocytes left their usual channels and passed between the elements of the other tissues likewise rendered it impossible to distinguish a non-malignant sharply from a malignant invasion of the surroundings. The ubiquity of the cells throughout the body threw difficulties in the way of recognizing true metastasis formation. After repeated failures with a considerable number of lymphomata involving homologous inoculation into many hundreds of normal mice it was decided to relinquish this direct attack, and, in the first place, to attempt a segregation of those growths which could conform to the behaviour of malignant new growths of other tissues by growing progressively when inoculated into the spontaneously affected mouse itself. The astonishing result was that even when local recurrence and progressive involvement of other lymph nodes occurred the autologous grafts failed to grow. Usually the latter were found as opaque white necrotic nodules, smaller than the piece of tissue introduced. The cells might still be alive, and in a few cases mitoses were seen in them, in others the process of absorption was in progress or complete. This striking contrast between the failure of the graft and the natural progress of the disease distinguished the new formations dealt with from the ordinary carcinomata and sarcomata, and made it difficult to believe that they were true malignant new growths. They were apparently in the majority of cases reactive hyperplasias, most probably of toxic origin.

Professor S. G. SHATTOCK observed that the difficulty of diagnosing a lympho-sarcomatous neoplasm from a lymphatic pseudoplasm was admittedly great; metastasis might, of course, arise in connexion with an infective process as well as in a sarcomatous. The test adopted by Dr. Murray was important, and the speaker saw no reason why it might not be applied in the human subject. For the excision of a small piece of a doubtful neoplasm, and its transplantation beneath, say, the loose skin of the dorsum of one of the fingers, would not be of serious moment; if the graft commenced to grow, it could be excised whilst still a local lesion. Theoretically it was not easy to understand why the transplantation of a lymphatic pseudoplasm should not, in Dr. Murray's experiments, have been followed by growth, seeing that any virus present in the tissue would necessarily have been transferred with the latter. In the human subject the evidence of autologous implantation might be naturally furnished by contact infection from one part of a serous cavity to another. The speaker had, for example, examined a diffuse thickening of the pericardium which histologically consisted simply of lymphatic tissue, but the opposite surface of the epicardium was the seat of a nannular and smaller nodular formations, highly sug-

gestive of contact infection; there were metastatic formations in the kidneys. If this was accepted as an instance of implantation, it would at least prove the existence of lymphosarcoma in man, the occurrence of which might seem to hang in the balance in view of Dr. Murray's research. At the same meeting Dr. J. W. CROPPER demonstrated a new counting chamber for the enumeration of protozoa and other organisms.

PRINCIPLES AND PRACTICE OF AMBULANCE WORK.

At a meeting of the Medical Society of London on February 25th, the President, Sir STCLAUDE THOMSON, being in the chair, Sir JAMES CANTLIE, K.B.E., F.R.C.S., defined ambulance work as the moving of injured persons as speedily as possible, either from the battle front to the base, or from the mine, the factory, the harvest field, or the street to the hospital. In military ambulance work the injured man was moved by bearers trained by the medical department of the army in time of peace; in civil life the training of the bearers was left to members of the medical profession under the direction of civil ambulance bodies, which were under the direction of laymen. In military work the medical department sent out trained men under its control to bring in the wounded, but in civil life surgeons and physicians waited for the injured to be brought to the hospitals, but took no responsibility or control for how or in what state the injured were to be brought to them. Universities and medical schools took no part in the training or teaching of first-aid bearers or ambulance workers. First aid, as now known, was a special branch of the surgical art, and those of the profession who wished to take it up had to go beyond their schools to acquire the knowledge necessary in either the practice or the teaching of the art. As a profession we shut our eyes to the condition of the wounded in the streets and took no care, for instance, to prevent the simple fracture from becoming compound and septic. At the Medical Congress in London in 1831 a demonstration of ambulance work was watched by Professor Eschsch, and on his return he called the population of Kiel to the University to be taught first aid. Britain was the originator of civil ambulance work, and had taught the world its meaning and purpose, yet the medical profession, as a profession, had taken no part in it, nor was there a great ambulance school in which this important branch of the surgical (and to a great extent the medical) art was taught. We wanted the best appliances, the best teachers, and our foremost surgeons and physicians to take the matter in hand. We had got beyond the stage in which we regarded a little knowledge as a dangerous thing. First aid, as it ought to be taught, was not a little knowledge—it was a definite part of medicine and surgery, and was complete in its limitations and its purpose. It was as distinct a department of surgery as, say, ophthalmology or dentistry. The welfare, the very life, of the injured was being dealt with by a section of the community whose business was neither surgery nor medicine, yet they were expected to carry on this important work apart from the control of those to whom the nation looked for direction in all matters of the healing art. It was to remove this defect that he had for many years in his mind the formation of a central institute where this great branch of surgery should be suitably housed, where its teaching should assume a technical if not a scientific perfection. It was for this purpose that the College of Ambulance was founded in 1914. The college had fulfilled its purpose inasmuch as it provided a central institute where all branches were taught, where models of all organs were to be found, and where drill room, ward, and operating theatre, etc., were at hand. Various methods of lifting and carrying were then demonstrated. Mr. HUGH LERT agreed that the omission of first aid was a grave defect in nursing and medical training. Mr. EDMUND A. RINSOR said there was a marked distinction between the case of the wounded soldier in the field and the injured in civil life. In the one case casualties were expected in considerable numbers, and their position known, whereas in civil life it was impossible to know when or where an accident would occur. Mr. FRANK HASTINGS, secretary of the British Red Cross Society, suggested that medical men should be

responsible for their own district, and that a system should be devised whereby the civil population should be trained to render first aid. Important work had been done by the Red Cross in improving the status of the trained nurse. Dr. HECTOR MUNRO and Dr. THOMAS LISTER also spoke. Sir JAMES CANTLIE, in his reply, said that the standardization of first aid work was very necessary, and should be carried out by the best talent in the medical profession. Specialists in the various branches of medicine and surgery should deal with the different sections of first aid and decide finally as to suitable methods.

RHINOPLASTY.

At a meeting of the Section of Laryngology of the Royal Society of Medicine, on February 1st, 1918, the President, Dr. BROWN KELLY, being in the chair, Major H. D. GILLIES and Captain G. SECOCOME HETT showed examples of rhinoplasty in various stages, and demonstrated photographs and models. The subject was reviewed from the repair of each portion of the nose that had been lost. Methods were classified and the difficulties and advantages of each put forward. Unsuccessful procedures were demonstrated, and the causes of failure pointed out. The advantages of utilizing the turbinate and septum in the formation of a lining membrane of the new nose and as supporting structures over which to mould the organ were shown and explained. The necessity for lining the new nose with either mucous membrane or skin was insisted on, and various new methods of epithelialization of frontal flaps and of the alae nasi in stenosis were illustrated with the aid of models and photographs.

Reviews.

HYGIENE AND PUBLIC HEALTH.

The object of Dr. CHARLES PORTER'S *Elements of Hygiene and Public Health*¹ is to provide the student and practitioner of medicine with a textbook containing knowledge essential to the doctor in general practice. The book is well suited to the needs of the medical student, containing just what he ought to know, but for the doctor who has been a few years in practice the information on many subjects is inadequate. The arrangement of the contents is different from that found in most English works, which usually proceed in the first chapter to the consideration of air and water; but we believe the author is right in placing immediately after his introduction chapters on personal hygiene and public health and disease. The treatment of notifiable and non-notifiable diseases in different chapters is surely unscientific, involving as it does the separation of paratyphoid fever from typhoid fever and the inclusion of anthrax and glanders among non-notifiable diseases simply because they are not notifiable to a local although notifiable to a central authority. The work bears evidence of an intimate knowledge of the whole field of hygiene. The material is well put together, and the interest of the reader is sustained throughout. A feature of the volume is the large number of illustrations, many of which are new and excellent. Altogether the book forms an admirable introduction to the subject.

The appearance of a thirteenth edition of WHITELEGGE and NEWMAN'S well known book on *Hygiene and Public Health*² is a sufficient indication that it has supplied a professional and public demand. The revision of the new edition has been carried out by Sir George Newman alone, and he has introduced much new material in regard to subjects which have assumed an increased importance, partly on account of the advance of preventive medicine and partly on account of the war; we need only mention such questions as infant mortality, tuberculosis, venereal diseases, and military, naval, and industrial welfare activities. There is no doubt that this manual fulfils its

object, which is stated to be "to summarize in a condensed and succinct form the most important applications of preventive medicine for the use of the medical student, the medical practitioner, and the health officer in every branch of the public service." The book is a mine of useful information, but is not easy reading, perhaps because it aims at too much. The accounts of the exact procedure employed in chemical, bacteriological, and immunological analyses might well be left to practical books treating of these subjects; the medical student is disposed to skip such matter, especially as it appears in small type, and the analyst will ask for more. In a subject of such wide range as hygiene it is difficult sometimes to decide what to include and what to omit. We find no mention of vitamins either in the chapter on food or in the section dealing with scurvy and beri-beri. Nor have we found any mention of Leiper's work on the life-history of the billharzial worm, which has put out of date the suggestion that one stage of it is passed in the body of a crustacean. Greater stress might have been laid on the use of antitetic serum as a prophylactic; the directions as regards intrathecal injection of the serum mentioned in the book are applicable to the treatment of actual cases of tetanus. Reference to *B. icteroides* in the etiology of yellow fever might well have been omitted, and in the section on typhus fever more room for modern investigations of its etiology and prophylaxis might have been found. The statement in the text that infection in typhus fever "is given off by the breath," and that "it is believed that the disease is largely spread by vermin, especially fleas and body lice," might make the student consider that the spread by body lice had no experimental or epidemiological evidence in its favour. Some good new illustrations have been added, but those depicting the meningococcus, the *Spirochaeta pallida* and the *Bacillus typhosus* are poor and unimstructive. These are minor defects, and it may be said that no book on the subject contains in the form of a handy manual such a wealth of accurate information on every branch of public health.

The sixth edition of PARKES and KENWOOD'S *Hygiene and Public Health*³ will be found to take a fair perspective of the whole field of sanitary science and to present the subject in a most readable and interesting form. It is not a cram book, and lucidity and style are not sacrificed to brevity. The work is brought thoroughly up to date, and bears evidence of careful discrimination in the introduction of new matter and the omission of what is no longer relevant. A new chapter has been added on maternity and child welfare work, and those on personal hygiene, camp sanitation, and communicable diseases judiciously amplified. We are in entire agreement with the authors as to the advantages of installing water-closets rather than incinerators in camps where this is at all possible. The printing, paper, and illustrations are good, and the whole subject is treated so clearly and thoroughly that it forms not only an admirable manual for the student and medical practitioner but also an interesting book for the general reader. We have noted a few mistakes in spelling—for example, Schiga and Zenopsylla should be Shiga and Xenopsylla. The only suggestion we would make is that the authors should include in their next edition an introduction dealing with the development and scope of hygiene and public health administration, as we find that too often students are disposed to regard it as one of the minor subjects. We congratulate the authors on a work which maintains the high standard reached in former editions.

The fourth edition of ROBERTSON and PORTER'S *Sanitary Law and Practice*⁴ will be welcomed. It has been brought up to date; some of the new material has been introduced into the text, but the bulk into appendices. In supplying practical suggestions as to the usual methods of administration followed by the medical officer of health and the sanitary inspector the book will be found useful not only to those who already hold these posts but also to those

¹ *Elements of Hygiene and Public Health. A Textbook for Students and Practitioners of Medicine.* By Charles Porter, M.D., B.Sc., M.R.C.P. London: Henry Frowde, and Hodder and Stoughton, 1917. (Cr. 8vo, pp. xiv + 411; 98 figures. 12s. 6d. net.)

² *Hygiene and Public Health.* By Sir Arthur Whitelegge, K.C.P., M.D., B.Sc., F.R.C.P., and Sir George Newman, M.D., D.P.H., F.R.S.E. Thirteenth edition. London: J. Cassell and Co., 1917. (Fcap. 8vo, pp. xii + 736; 77 figures and diagrams. 10s. 6d. net.)

³ *Hygiene and Public Health.* By Louis C. Parkes, M.D., and Henry R. Kenwood, M.B. Sixth edition. London: H. K. Lewis and Co., 1917. (Demy 8vo, pp. xii + 787; illustrated. 14s. net.)

⁴ *Sanitary Law and Practice. A Handbook for Students of Public Health and Others.* By W. Robertson, M.D. Glas., D.P.H., and Charles Porter, M.D., B.Sc., M.R.C.P. Edin. Fourth edition. London: The Sanitary Publishing Co., Ltd. 1917. (Demy 8vo, pp. xxiii + 750; illustrated. 12s. 6d. net.)

who are preparing to qualify for them. It is well written, and the treatment of theory and practice well balanced. The authors have succeeded in placing in the hands of the student a guide which will make his study of what is usually a dry subject quite interesting. We can most heartily commend this volume to the attention not only of the medical graduate studying for the Diploma of Public Health but to all who are interested in the social welfare of the people and who wish to be acquainted with the present position of our country in this extremely important matter. The illustrations are few in number but good.

The moment is timely for the publication of a book on *Public Health Nursing*, and Miss MARY S. GARDNER deserves congratulation for her lucid presentation of a subject which is daily growing in importance as a most essential part of the public health work. Miss Gardner, as president of the American National Organization for Public Health Nursing 1913-16, knows her subject from within, and British readers will find that due prominence is given to the pioneer work in England. In spite of the differences in administrative organization in England and the United States the book will be as inspiring and instructive to British readers as to Americans. The work is divided into three parts. Part I treats of the public health nursing movement, its history, its fundamental principles, and the problems it encounters at the present time. Part II deals with visiting nursing, and in it will be found words of wisdom useful to all concerned in the movement, whether members of visiting nursing associations or persons employed by them. Part III contains chapters on tuberculosis nursing, child welfare nursing, school nursing, mental hygiene nursing, industrial nursing, and medical social service, and on records and statistics. This enumeration indicates the scope of the book and incidentally shows how important a part in preventive medicine the nurse is playing at the present time. It is in the domain of personal hygiene that progress is now most required, and this is the sphere for educated tactful sympathetic women who have pursued a proper course of training and have access to the homes of the people. Little reference is made to the question of venereal disease; we would have welcomed the opinion of the writer as to the position of the nurse as regards its prophylaxis and treatment. The book should be in the hands of all social workers and of all interested in the training of the nurse not merely for the treatment of disease but for its prevention.

In his book entitled *State Sanitation* Professor G. C. WHIPPLE presents a review of the work of the Massachusetts State Board of Health. There are to be three volumes. The first, which is before us, is divided into two parts. Part I contains the history of the State Board of Health, and Part II the report of the Massachusetts Sanitary Commission of 1850. The book forms a worthy memorial to the men who have made the name of Massachusetts familiar to all sanitarians and especially to those interested in water and sewage purification. The author shows how the State Board of Health has fulfilled the ideals set forth by Lemuel Shattuck in the "Report of the Massachusetts Sanitary Commission of 1850," and in this volume can be read in Part I what has been accomplished, and in Part II what Shattuck considered practicable. An interesting chapter contains short biographical sketches of the sanitarians of the Commonwealth. The volume is a valuable contribution to the history of sanitation. The print is large and clear, the paper good, and the illustrations excellent.

NOTES ON BOOKS.

DR. BROOKBANK'S elementary *Diagnosis and Treatment of Heart Disease* has rapidly passed into a third edition, and is thus proved to supply a definite want. A new chapter on

the general physical signs and symptoms of heart disease and a number of clinical points have been added. Dr. Brookbank naturally maintains his contention that the crescendo murmur of mitral stenosis occurs in the early part of ventricular systole, and so is presphygmic not presystolic in rhythm. It would perhaps be well in a future edition to alter the statement that digitalis raises the arterial blood pressure. The treatment of angina pectoris between the paroxysms by dilute phosphoric acid, which is said to be followed by great freedom from attacks, and is hinted to remove calcareous deposits from the coronary arteries and to prevent their further deposition, is new and rather surprising, but is possibly worth further investigation.

The first edition of REMINGTON'S *Practice of Pharmacy* appeared in 1885; the sixth has just been issued, with apologies by the editor, who had on this occasion the assistance of Dr. L. FULLERTON COOK, for an increase in its size. It is described as a handbook for pharmacists and physicians, and a textbook for students, but it will, perhaps, be more particularly useful to pharmacists; one of its special features is an unusual number of illustrations of pharmaceutical appliances. The chapter on prescriptions is illustrated by facsimiles of many very curious specimens, some of which we find illegible, though they appear to have been deciphered by the pharmacist; several are curious examples of polypharmacy; thus one of them contains twenty-nine ingredients, another twenty-two. The book is adapted to the United States Pharmacopoeia. In a final section a formulary of unusual preparations and a glossary of uncommon names, terms, and substances are provided. There is a good index.

Practice of Pharmacy, by J. P. Remington, Ph.M., Ph.D., F.C.S., assisted by L. Fullerton Cook, P.D. Sixth edition. Philadelphia and London: J. B. Lippincott Company. (Medicine 8vo, pp. xxviii + 1947, 25s. net.)

DIMINUTION OF PAGES IN THE "BRITISH MEDICAL JOURNAL."

FURTHER RESTRICTIONS BY THE PAPER COMMISSION.

THE Paper Commission has issued an Order under the Defence of the Realm Act reducing the licences for the importation of paper and paper-making material in the year beginning March 1st, 1918, to two-thirds of the tonnage imported in the year ending February 28th, 1918. This reduction takes effect on a supply which had already been reduced by one-third, owing to previous orders by the same authority. This means that the amount of paper available in 1918 will be half, or rather less than half, the amount available in 1915. The number of pages in the weekly issues of the JOURNAL must therefore be reduced in this proportion.

This reduction in the number of pages is not a matter in which the Association has any choice. The Council at its last meeting adopted the following resolutions:

PAPER SUPPLY.

1. That an announcement be made in the *BRITISH MEDICAL JOURNAL* on the authority of the Council drawing the attention of Members to the fact that from the first issue in March the number of pages of the JOURNAL must be still further reduced by one-third, and particularly to the following points:

(1) That this reduction is not a matter of choice with the Council, but compulsory under the Defence of the Realm Regulations; and

(2) That, as in the case of other rationed articles, there is no guarantee that a sufficient supply of paper or paper-making materials will be available in the country to furnish to each consumer the proportionate minimum quantity permitted under the amended regulations.

The aim must be to maintain a due balance between the different departments of the JOURNAL to each of which large sections of its numerous readers attach importance, and this principle must be applied also to advertisements. The aim can only be satisfactorily attained if all members of the Association who desire that their observations and opinions should find expression in the JOURNAL will frankly recognize the position that has been brought about owing mainly to the necessity of diverting shipping to the transport of food and of the raw materials and implements of war.

British Medical Journal.

SATURDAY, MARCH 2ND, 1918.

WOUND SHOCK.

In last week's issue of the JOURNAL we dealt with two of the reports of the Special Investigation Committee on Surgical Shock and allied conditions, deferring for further consideration the papers dealing with an investigation of the nature and treatment of wound shock. Of the six papers constituting this report, five are clinical studies of the circulatory functions, which, "whatever the nature of the bodily changes which underlie the state of shock, . . . are in a precarious condition."

The contribution on the initiation of wound shock by Captain H. M. Cowell, R.A.M.C.(S.R.), is a valuable and highly interesting study of blood pressures among soldiers in forward areas and the front line in "peace" and in active periods. He comes to the conclusion that "the psychology and physiology of the average healthy 'veteran' soldier, living in the fighting zone under 'peace' conditions, are for practical purposes normal," but at times of increased activity, although the pressures are invariably above normal, the conditions of excitement, cold, thirst, fatigue, and possibly loss of sleep, become important pre-wound factors in the initiation of shock. He classifies wounds, and finds that "trivial" wounds give rise neither to primary nor to secondary wound shock; with moderately severe wounds primary shock is generally absent, and the secondary form may be averted if conditions admit of proper precautions being taken. Serious wounds, that is, those likely to be mortal, are attended by primary shock, which, generally speaking, merges insensibly into secondary, notwithstanding efforts to avert the injurious influence of cold, pain, anxiety, a long "carry," and, in the case of survival, toxæmia. These are the usual, theoretically preventable, causes. Wound shock as seen at casualty clearing stations, where the majority of these clinical studies were made, is in fact secondary shock.

Captains John Fraser and Cowell give an elaborate account of the sphygmomanometric findings in the most important types of wound, the full value of which appears later. Incidentally it bears out Bayliss's experimental investigation of the relative value of various intravenous injections, and also suggests that similar observations may be useful for prognosis. A wound running a favourable course shows a steadily maintained blood pressure; the onset of gas gangrene or other infection is signalized by a sudden fall; a steadily rising or maintained high pressure reading, even in a severe wound, may be taken as a most favourable prognostic sign.

Professor Cannon, of Harvard, and Captains Fraser and Hooper relate the results of venous and capillary red counts, with hæmatocrit and hæmoglobin readings in cases of low blood pressure. In shock, with a normal venous red count, the capillary count is higher by as much as 2 millions per cubic millimetre, and the discrepancy bears a direct relation to the

depth of the shock. Hæmatocrit and hæmoglobino-meter readings confirm these findings, which are interpreted as indicating that the "lost" blood in shock is hidden in the general capillary system and not in the veins of the splanchnic area. Once established, concentration of capillary blood persists for two or three days; further persistence is of bad omen, and conversely. On the other hand, continued dilution after four or five days suggests an unfavourable prognosis.

Professor Cannon reports also the results of an investigation into the diminution of the alkali reserve in shock, and reaches the conclusion that bodily states characterized by reduced blood pressure, and consequently by defective circulation, are accompanied by such a diminution, or "acidosis," and that, broadly speaking, the lower the pressure the lower the alkali reserve. Haemorrhage alone is attended with less reduction of the alkali reserve than wound shock; the maximum reduction is seen in cases of gas infection. Operation and anaesthesia reduce the alkali reserve, but the encroachment is greater as the margin of safety is less: the marked and sudden decrease of the alkali reserve in the blood is accompanied by serious and rapid sinking of arterial pressure. Acidosis, even extreme, can be relieved by the administration of sodium bicarbonate. The most important outcome of the studies is, perhaps, the indication that a very low blood pressure—an easily and rapidly observed fact—is almost certainly attended by that grave diminution of the alkali reserve which makes operation perilous, but which is remediable by administration of sodium bicarbonate intravenously before or during operation; moreover, the diminution can be minimized by systematic administration of bicarbonate in sweetened drinks at every point from the aid post down to the casualty clearing station.

A paper, by the same three authors, on the application of these findings to the preventive treatment of wound shock, for anything novel that it offers, seems rather a "small mouse," but of course everyday practice has not waited on publication, so that nearly everybody is already familiar with the measures suggested, though the details should certainly be circulated; and it is satisfactory to learn that the proper gum and bicarbonate solution is to be provided in sterile bottles ready for use.

Yet another paper by Professor Cannon, a consideration of the nature of wound shock, is of a different order. Some of its paragraphs, as their very language shows, are of a highly speculative character, whilst the work of Henderson, Crile, and others is, as it were, "dealt with kindly but firmly." The outcome of his study of the results of this work and Bayliss's and other research along the same lines, is that the condition met with in hospitals in forward areas, and here called secondary wound shock, would be best described as "exæmia," implying that, as a consequence of fall of blood pressure, diminution of alkali reserve, alteration of viscosity, and perhaps other inter-related factors, blood is lost from currency, and vitality imperilled. It is comforting, at any rate, that "exæmia" is amenable to simple remedies; they ought to be and are being put into universal practice. This is not to say that the whole problem of shock has been solved, and probably for that very reason the Committee has not as yet issued these reports for sale, looking upon them as interim contributions useful to workers elsewhere. All the work is valuable, and Captain Cowell's observations in the trenches under bomb fire are deserving of the highest praise.

MASSACHUSETTS AND PUBLIC HEALTH.

A RECENT work by that distinguished American sanitarian, Professor George Chandler Whipple, puts on record the great services rendered by "the glorious old Bay State," Massachusetts, to the cause of sanitary science. In America, as in England, it is the existence of large waterworks, systems of sewage disposal, baths and bath-houses, the provision of parks and playfields, the supervision of the health of the mother, the child, and the worker, and of the quality of the food consumed by them, rather than learned treatises on the subjects, which make the English-speaking race leaders in practical hygiene. In democratic countries the existence of such works and institutions implies the presence of an enlightened public opinion. In producing this a large part is played by the epidemic visitations, and still more by the work of enthusiasts in the cause of hygiene and sanitary reform. In England Edwin Chadwick and in America Lemuel Shattuck will always find an honourable place in sanitary history—a history really dealing with the lives of the people, their health, comfort, and physical and moral welfare. Neither of these eminent men belonged to the medical profession, but as a profession we are proud to claim that it was the *Reports of Fevers in London*, by Neil Arnot, M.D., James Phillips Kay, M.D., and Southwood Smith, M.D. (1838), which caused action to be taken. Their work gave an opportunity to Edwin Chadwick, the secretary of the Poor Law Commissioners, to issue his epoch-making *Report on the Sanitary Condition of the Labouring Population of Great Britain* (1842), which led Parliament to pass an Act for promoting the public health in 1848.

In Massachusetts the problems involved in the prevention of disease early obtained attention. Thus Jenner never had more enthusiastic and faithful disciples than Drs. Waterhouse and Jackson of Boston. Dr. Waterhouse, on July 8th, 1800, vaccinated seven members of his own household. Shortly afterwards, as a convincing test, three of the children were sent to the small-pox hospital, and one was even inoculated with small-pox matter, but none of them contracted the disease.

In 1848 the provision of abundance of wholesome drinking water was undertaken in Massachusetts. The disposal of waste and sullage water was dealt with in an Act passed by the Great and General Court or Assembly of Her Majesty's (Queen Anne) Province of the Massachusetts Bay in 1709. Under this Act for 115 years the sewers of Boston were built, repaired, and owned by private individuals. The results of this lack of central responsibility were a highly insanitary condition of the soil and interminable disputes between owners of property. The City government assumed control of the sewers in 1823, and in 1833 the passage of liquid sewage from cess-pools into them was permitted. In 1849 the Commonwealth of Massachusetts appointed three commissioners to make a sanitary survey of the State. Lemuel Shattuck wrote their report, which was published in 1850, and sketched an ideal of public health administration quite within the range of practical attainment at the time. But, as Dr. Bowditch has put it, this report "fell stillborn from the hands of the State printer." Not till 1860 was the time ripe for Shattuck's ideals, and in that year an Act creating the State Board of Health was passed. The board consisted of seven members, of whom three were physicians, one a lawyer, one a civil engineer, one a historian, and one a business man.

The first chairman of the board was Henry J. Bowditch, whose name is familiarly linked with that of Buchanan in England as the sanitarian who showed that the spread of consumption is closely associated with dampness of the soil. "The State Board of Health was founded on a noble ideal, and has been supported by sound public sentiment. Its organization and work have been non-partisan; its functions have been conceived to be advisory rather than coercive, educational rather than punitive; yet, when occasion required, it has not hesitated to demand the exercise of the police power of the State through its legal machinery. By co-operating with other State departments, metropolitan boards, and local authorities, it has given them the advantage of its knowledge and the services of its experts. The State Legislature has liberally supported it, and last, but by no means least, it has maintained a remarkable personnel." It was good policy of the board to invest its money in brains and not in buildings—and here some of our universities might note and learn—and it was able to attract the services of the very ablest men in the country. The reports of the board contain the results of investigations in every field of public health. It is interesting to note that in a paper on the ventilation of schoolhouses Mr. A. C. Martin, an architect of Boston, contested the current view that carbonic acid was the chief noxious ingredient of vitiated air: he held that watery vapour and animal matter given off by the lungs and skin were of greater significance. The recent work of Leonard Hill has emphasized the importance of moisture, heat, and stagnation of the air in causing the symptoms produced by a vitiated atmosphere.

In 1886 the State Board of Health was reorganized under the chairmanship of Dr. Henry P. Walcott, who held this post for twenty-eight years and carried out his duties with such thoroughness and exercised such discrimination in the selection of the personnel of the officials of the board as to attract to the work done in Massachusetts the attention of the whole sanitary world. So far as the purification of water and sewage are concerned it is not too much to say that the board's experiments were of capital importance. They showed that the oxidation of the organic matter was not a physical action alone and was not dependent upon the passage of sewage through fine material, as the process of nitrification occurred in coarse gravel filters as well as in those of sand. This germinal idea was developed by English sanitarians and led to the extensive use of contact beds and trickling filters, which have rendered the problem of sewage disposal so much simpler. The work at the Lawrence experiment station in Massachusetts has shown that instruction in biology, and especially in bacteriology, should enter into the curriculum of the engineering student, and this is now being recognized by some British universities.

The Massachusetts State Board of Health took the lead in 1895 in a movement having a more direct medical bearing than those hitherto undertaken—the manufacture and free distribution of antitoxin and vaccine lymph. Here the board was fortunate in securing the services of Dr. Theobald Smith, who had just been appointed Professor of Comparative Pathology in the Harvard Medical School. Soon the scope of the bacteriological work was extended so as to include examination of sputum, blood, and secretions for evidence of the presence of infecting germs.

Harvard University and the Massachusetts Institute of Technology contributed greatly to the success of the enterprises of the board. In 1914 an Act was passed creating a State department of health, under

which a commissioner of health, with a public health council of seven, the commissioner himself being the eighth member, exercise all the powers and perform all the functions of the State Board of Health. Four of these members are physicians, one is a hygienist, one a biologist, one a sanitary engineer, and one a lawyer. The Public Health Council is organized into three separate standing committees. The salaried force is arranged into seven divisions, each in charge of a director, who reports to the Commissioner of Health. The work of this new and elaborate State Department of Health will be watched in this country with interest. We may learn from the experience of our cousins and staunch allies in the Commonwealth of Massachusetts much which will be of value to us in the task of setting up a Ministry of Health.

SIR ALFRED KEOGH.

SIR ALFRED KEOGH has this week vacated the office of Director-General A.M.S., and has been welcomed at the Imperial College of Science and Technology on resuming the office of Rector. In the debate on the Army Estimates, reported elsewhere, Mr. Macpherson, the present Under Secretary for War, and Mr. Tennant, who held that office in the early days of the war, both paid very high tributes to his magnificent work during three and a half difficult years, and we know that he has recently received many private expressions of the admiration and esteem with which his work is regarded by those who have been most intimately associated with him in the conduct of army medical affairs since a very early stage of the war. We desire to associate ourselves with these tributes to a great public servant. We have had occasion recently to criticize some aspects of army medical administration, especially in respect to the organization of the home Commands, and to suggest certain changes which will, we believe, make for economy and greater efficiency. We know that in calling attention to these defects we have only expressed the views of a large number of medical men of wide civilian experience; but the belief that the machine can be made to run better does not blind them or us to the great qualities of the man who has been in charge at home through a period of unexampled stress. As we said when his approaching retirement was announced, Sir Alfred Keogh has shouldered day after day a burden of responsibility and labour which only a man of his energy, enthusiasm, and mental calibre could carry. In the earliest stage, putting into action a scheme he had brought into existence during his first term of office, he turned to the civilian profession for assistance, and it was very fully given. The military hospitals with their staffs, for which the Territorial scheme provided, were quickly in working order, and the plan proved capable of great extensions. In the army abroad the methods elaborated before the war for the prevention of diseases of the typhoid group have worked on the larger scale with a success beyond the hopes of the most sanguine. When new problems arose—such as that created by the frequency and severity of wound infections—resort was freely had to scientific research and clinical experience to overcome them, and step by step they have been overcome; and so with other problems as they have arisen. Nothing that energy, knowledge, or money could provide has been spared for the benefit of the soldier. The bulk of the British Forces are engaged on the Western front, and in no other war have the wounded experienced so many alleviations of their lot as have been provided for them there. The work has all been done in a spirit of comradeship between regular officers and those drawn from civil life which reflects honour on both. In the institution of clinical and laboratory inquiries, and in the application of results to treatment, the directing hand of Sir Alfred Keogh has

everywhere been felt. The debt of gratitude due to him by the nation and by his own profession cannot be paid, but it will not be forgotten.

THE NEW CHARTER OF THE LABOUR PARTY.

THE Labour Party has enlarged its constitution, and in future will receive within its fold professional men who may be willing to subscribe to its articles of faith—which, however, are to be susceptible to change. When the new charter was submitted to the conference at Nottingham last month there was hesitation, and by a small majority on a card vote, it was referred to the adjourned gathering, which was held in London last Tuesday. Then the opposition broke down, and, subject to some small amendments, the original recommendations of the executive were adopted. It is interesting to notice what were the two lines of objection to the change. The trade unionists were at first divided—a number fearing that the party would lose its essential character, and therefore its vitality, from the addition of members not belonging to what may be called the crafts. The Independent Labour Party, and other pronouncedly socialist bodies, were perturbed because their over-representation on the executive which existed under the old method of election would be ended. The ease of the first-named was met by an amendment which increases the representation of national organizations on the Executive Committee from eleven (which was originally proposed) to thirteen, the representation of local organizations being left at five, and the representation of women at four, which were the figures in the draft plan. Thus the Executive Committee will comprise twenty-two members, of whom thirteen will be trade unionists. The Independent Labour Party, in its effort to keep up separate representation, suffered defeat by an overwhelming majority. Whatever strength it has will be exercisable only in the ordinary voting. No special party representation is to be allowed. The trade unionists, the local parties whose organizations will be according to constituencies, and the women, will be the power behind the machine—that is, behind the Executive Committee as elected and controlled by conferences. The charter, with its arrangements for local elections, for framing and varying policy, for support of candidates for seats in Parliament or on local authority, is practically what it was when we noticed it in draft in the issue of the BRITISH MEDICAL JOURNAL of December 15th. The feature of the enlargement of the scope of the party is the appeal to workers by head to join workers by hand in becoming members by obtaining admission to local parties, which, as already indicated, will be made up on constituency bases. Mr. Henderson, in his book *The Aims of Labour*, says the “net is being cast wide” because it is “realized that real political democracy cannot be organized on the basis of class interest.” The four principal aims foreshadowed in the memorandum on “Labour and the new social order” are: (1) The universal enforcement of the new national minimum wage; (2) the democratic control of industry; (3) a revolution in national finance; and (4) the surplus wealth for the common good. In his speeches Mr. Henderson has said there is no intention that anything should be done suddenly or violently. Phrases of the kind just quoted are elastic enough to be capable of greatly varied interpretation according to individual opinion and desire. As regards consideration for capital, it has to be remembered that the trade unions themselves have large financial interests, and may be expected to shun Bolshevism like a plague. But the new organization opens fresh political possibilities, all the more uncertain because the Reform Act has added so many more millions to the electorate.

GERMAN RED CROSS “LADIES.”

Boys of a past generation used to read Fenimore Cooper's stories of Red Indians. His books seem to have gone out of fashion, although, as his biographer says, he had considerable powers of description and could tell a tale of

adventure as well as most. The hero sometimes was captured by the red man and taken to the camp to be tortured. Occasionally his courage and noble demeanour appealed to the braves, who might be disposed, if not to save his life, at least to excuse the preliminary atrocities. But, if this happened, the women of the tribe demanded the utmost rigour, showing themselves more cruel than their men. Since those days the Red Indian has risen in the scale of culture, and to-day has not only enlisted in large numbers to fight in the cause of freedom, but has subscribed largely to the Red Cross. Judging from her conduct to British prisoners of war, as related in a white paper¹ on the transport of British prisoners of war to Germany, the German woman is still in the primitive stage of ethical development out of which the Red Indian has emerged. Not only did the German officials discriminate against British wounded taken prisoners early in the war, but the German "ladies" of the Red Cross deprived British wounded of food and even of water, and insulted them, and tantalized them by showing food to the starving prisoners and then removing it, and by bringing water and soup in cans and pouring it out on the platform in front of the English. The women, the report says, "were extraordinarily venomous in preventing anything from reaching the prisoners, and their general display of spite, their heartless cruelty, their profusion of gross insult were barbarous beyond all words. One officer tells how a woman of the Red Cross brought him a glass of water, spitting in it first. Very occasionally it would happen that a German officer would order one of these women to bring something for the prisoners, which she would do most unwillingly, and even with *averted face*" (italics in report). Well-dressed women were constantly prominent in the scenes of insult and outrage at railway stations, and at some wayside places rows of school children had been drawn up and chanted choruses of abuse. When the prisoners reached their place of confinement they were marched through "immense spitting, threatening crowds, mostly well-dressed people of the middle classes, which thronged the streets." German officers often took an active part in these pitiable proceedings, but the British prisoners received some kindnesses from their Senegalese fellow prisoners, and some of the German rank and file would give them a little of their own food "when there was no chance of their being seen by the ladies of the Red Cross." The Government committee on the treatment by the enemy of British prisoners of war, which has drawn up the report, takes care to quote the statement that in one instance "the Red Cross behaved very decently"; but it is added, "in view of the evidence there can be little doubt that the reference is to the German Army Medical Service, not to the Red Cross Society." The report states that the "persistent degradation of the Red Cross, universal emblem of charity in warfare, caused the deepest possible impression on the British prisoners, both officers and men." The behaviour of the German Red Cross is declared to have been "most revolting," and the fact makes it difficult to accept the distinction President Wilson wished to draw between the German people and their Hohenzollern rulers. The German Emperor may be personally responsible for the torpedoing of the *Lusitania*, as Mr. Gerard holds, and for the sinking of hospital ships, of which we have another instance this week, but he can hardly have ordered German Red Cross women to spit in the water before handing it to the wounded, or German ladies in evening dress to shout and shake their fists from an open window as the prisoners were marched through the street.

A NEW SYPHILITIC SYNDROME.

THE Wassermann test is constantly adding presumptive evidence in support of the view that syphilis is the underlying factor in many chronic diseases of obscure origin.

This is particularly true as regards the nervous and vascular systems, whereas the alimentary, and especially the respiratory organs, still offer opportunity for further application of this generalization. Luetic affections of the liver and pancreas are, of course, sufficiently well recognized, but the high percentage of positive Wassermann reactions in ordinary cirrhosis has again raised the old view of a syphilitic origin. Sometime ago the possibility of a relation of syphilis to appendicitis was raised, but the suggestion was unsympathetically received. There appears to be more reason to consider Leredde's¹ contention that the definite syndrome of severe dyspnoea on exertion dating from early life or adolescence, combined with advanced emphysema, recurrent attacks of acute febrile bronchitis, and often with asthma, is a remote sequel of syphilis, usually congenital, and characterized by fibrosis. The acute attacks are evidently a complication depending on special liability to infection. Out of 20 of such cases 7 gave a positive Wassermann reaction, and among the remaining 13 there were undoubted clinical manifestations of syphilis in all but two. Antisyphilitic treatment, especially arseno-benzol in gradually increasing doses, is recommended.

VISITS TO FOREIGN HEALTH RESORTS.

We are informed that the Military Permit Office has been instructed to reduce all cross-channel traffic to the lowest limits consistent with the national interest and the avoidance of unnecessary hardship to individuals. Permits are now limited to those cases only in which the absolute necessity of the journey can be satisfactorily established. Before any application which is made on the ground of ill health is considered the applicant is required to produce a doctor's certificate stating that the journey is an absolute necessity, specifying the place to which the journey is to be made, and the length of stay there, and certifying that there is no health resort in Great Britain which would meet the case; when the application includes a request for a companion the medical man must include in his certificate the statement that a companion is essential, and the name of the companion. These regulations do not apply to persons seeking permission to visit a wounded relative. The regulations, therefore, appear to apply solely to persons who consider that it would be to the advantage of their health to visit some place on the Continent, most usually the Riviera. We have been asked to bring the decision of the Military Permit Office to the notice of members of the medical profession and to invite them to exercise the utmost discrimination in giving certificates. The essential points seem to be that the doctor must certify that the journey is an absolute necessity, and that there is no health resort in Great Britain which would meet the case. It is clear, therefore, that the total number of medical certificates to this effect which need be given must be extremely limited; in fact, we find difficulty in thinking of any condition as to which it could be said that there is no health resort in Great Britain which would meet its needs.

THE LIFE-HISTORY OF ASCARIS LUMBRICOIDES.

INFECTION with the round worm is a comparatively uncommon and comparatively trivial affair to dwellers in Great Britain. But this worm has a cosmopolitan distribution, and ascariasis, or the condition of infection with it, is an important matter in hot countries. Indeed, Major F. H. Stewart, I.M.S., some of whose work on the subject has already been published in the *BRITISH MEDICAL JOURNAL*,² goes so far as to state that "there is reason to suppose that a great deal of the debility of the natives of the tropics is due to ascariasis, and that this disease is

¹ Leredde, *Paris méd.*, 1917, vii, 225.

² *BRITISH MEDICAL JOURNAL*, July 1st, October 7th, and December 2nd, 1916.

at least the equal of ankylostomiasis in economic importance." Major Stewart has published in the current issue of *Parasitology* an account of some further experiments designed to clear up obscure points in the life-history of *Ascaris lumbricoides*, which occurs in man, and *A. suilla*, which infects pigs. More particularly he has endeavoured to determine whether these ascarids normally complete their life-cycle in a single host, or, alternatively, require an intermediate host for their development, such as the rat or mouse, before maturing in the definitive host, man or pig as the case may be. There is good reason for believing that in human beings, pigs, rats, and mice the eggs of these ascarids when ingested by the mouth first develop into larvae in the lungs and tracheae of their hosts. Can these larvae then enter the alimentary tract and develop into the corresponding round worms? The question is one that should be capable of fairly easy solution, as Major Stewart points out. His own experiments, unfortunately interrupted before completion, are not in favour of the theory of direct development without an intermediate host. But they leave the question still open. It is interesting to note that the development of fever and dyspnoea, evidence of pulmonary involvement, a few days after the ingestion of several dozen eggs of *A. lumbricoides* by children, was observed by Mosler as long ago as the year 1860.

VENEREAL DISEASES.

THE KING's visit last week to the Rochester Row Hospital was publicly stated to be due to His Majesty's recognition of the importance of the movement dealing with venereal diseases, and his sympathy with the practical efforts now in progress to combat this national danger. A royal visit to a hospital for venereal diseases is an encouraging sign of the changed outlook on this problem, and there are other indications of improvement. Thus, in a circular issued by the Local Government Board on February 22nd, on the prevention and treatment of venereal diseases, the President records his appreciation of the fact that county and borough councils generally have shown their readiness to undertake the new duties imposed by the regulations, and have been successful in a large majority of cases in their negotiations with hospital authorities and other bodies for the provision of the necessary facilities for diagnosis and treatment. The circular goes on to point out that for certain classes of cases additional accommodation is needed, and should be provided wherever possible. Thus, the treatment of lying-in women and expectant mothers suffering from venereal disease is a matter of national importance both in the interests of the mothers and of their offspring. Councils are therefore urged to consider what steps can be taken to secure additional accommodation for these cases either by obtaining beds at existing lying-in or general hospitals, or, failing these, at special institutions or nursing homes. The Board will be prepared to make a grant of 75 per cent. of all expenditure approved by it for this purpose. In this connexion the Board draws attention to the importance of the Wassermann test for patients who have had miscarriages, and of examinations of material from cases of stillbirth. It is deemed desirable that when these cases are notified the medical officer of health should make discreet inquiries into the circumstances through the medical practitioner in attendance. Lastly, the circular refers to the need for special accommodation in the form of hostels for certain classes of women and girls, such as shop assistants and domestic servants, who are infected with venereal disease and whose home conditions are not satisfactory. The Board encourages councils to contribute towards the maintenance of satisfactory hostels, and is willing to make a grant of 75 per cent. of the amount of any contribution approved by it. We may also refer to a circular to medical

practitioners on the subject of venereal diseases issued recently by the Public Health Department of the London County Council. This emphasizes the need for the hearty co-operation of the medical profession in the Council's scheme for dealing with these diseases. Details are given of the special facilities which, after conferences with representatives of the medical profession, have been provided at the twenty-five hospitals with which the Council has entered into agreement. Dr. W. H. Hamer, the medical officer to the Council, expresses the hope that medical practitioners will take the fullest possible advantage of all the facilities provided, and communicate with him should difficulty be experienced.

Medical Notes in Parliament.

The Air Medical Service.

IN the House of Commons, on February 21st, Major Baird, the Parliamentary Secretary to the Air Ministry, presented the estimates for the coming year, and made a lengthy statement as to the reconstitution of the air forces. Speaking of the medical service, he said that a committee, under the chairmanship of Sir Watson Cheyne, had, at the request of the Air Board, drawn up a scheme for a medical service. Major Baird hinted that there was some apprehension on the part of the army that a separate air medical service might lead to friction. He claimed, however, that the arrangement made met the views of the navy and the army, and would render it possible to carry into effect the system advocated by the committee. The two indispensable conditions—that medical officers responsible for the care of the officers and men serving in the air should specialize in that particular branch of medical science, and should not be changed indiscriminately—had been secured. It had been agreed by the War Office and the Admiralty, with the assent of the Treasury, that the medical affairs of the air force should be controlled by a committee responsible to the Air Council, and composed as follows: The Director-General of the Naval Medical Service, the Director-General of the Army Medical Service, the Vice-President of the Air Council, a Medical Administrator of the air force, an Assistant Medical Administrator who would act as secretary, one neurologist, one physician, one surgeon, one physiologist, and the secretary of the Medical Research Committee. The Medical Administrator would be given the substantive rank of surgeon-general, and the Assistant Medical Administrator that of lieutenant-colonel. The Medical Administrator would nominate an executive staff of medical officers, and would arrange for the necessary clerical assistance. He would be given discretion to take action on any matter of urgency, and on matters of detail arising in the intervals between the meetings of the committee. The medical arrangements of the air force would be centralized under the direction of the committee as soon as possible. All medical appointments would be made by the President of the Air Council on the nomination of the committee. Officers appointed to the air force medical posts would be seconded to that force. Temporary air force commissions would be given to all those, whether already officers or not, appointed to executive medical posts, but a limited number of officers would be nominated by the committee for permanent commissions. All medical officers appointed to the air force would wear air force uniform. Officers seconded from the army and navy would receive an assurance in writing that their prospects of promotion by selection in their own services would not be prejudiced thereby. The Medical Administrator would have direct access to the Secretary of State for the Air Force, and the medical arrangements of the air force would be dealt with in the department of the Master-General of Personnel.

In the course of the debate Mr. Joynson-Hicks, after some general congratulations on the improvements in the air service, said it would have been better to have established a special medical air service apart from the Royal Army Medical Corps. Referring to the necessity that a technically trained physician should be appointed for every detachment of the air service at home, Mr. Joynson-Hicks remarked that he could take Major Baird, who had trained a detachment in this country, with 700 or 800 men under training, who not only had no medical man attached to them, but whose aerodrome was not even in telephonic communication with a medical man. The

condition of things must be altered at the earliest possible moment. Touching the question of accidents, Mr. Joynson Hicks asked that the system of training airmen should be overhauled. He quoted with particular appreciation the article by Mr. Graeme Anderson which appeared in the *BRITISH MEDICAL JOURNAL* in January, with particulars of investigations extending over six months.

Sir Watson Cheyne, in dealing with the medical aspects of aviation, said that the human being was constructed to live upon the earth, and all his mechanisms were delicately linked together for living under those conditions; he was not constructed to live under water, or up in the air. The two important conditions, so far as was known at present, were the atmospheric pressure and the density of the air—the density of the air especially, because with a suitable density the proper amount of oxygen was available. People might live on the sea level, or 5,000 or 6,000 feet above the sea level, and could go from one to the other without great discomfort, if the transition was not too quick. A day or two was spent by mountain climbers in reaching 10,000 feet, but a flier went up 10,000 feet in a few minutes, and the human mechanism had not time to adapt itself. This was especially true when that height was exceeded. As the aviator mounted he came into air that did not contain so much oxygen as was necessary; to take in the required amount he began to breathe faster, and the heart beat quicker, until, at a considerable height, the heart began to fail, the man began to lose consciousness, and might actually faint. Although that was not always fatal, because of the steadiness of modern machines, a good many never recovered from that faintness, or, if they did, found they were dashing to their doom. Nowadays aviators were provided with oxygen for inhalation, but they differed very much in the heights to which they could go without employing it. Almost more important than heart and lungs was the nervous system, which, up in the air, was acting, quite unconsciously to the individual, under great strain in maintaining equilibrium. He did not know that any aviators were consciously frightened, but their nervous system was frightened. Although the aviator had no feeling of fear, the brain was getting exhausted in its efforts to overcome the dangers surrounding him; exhaustion came specially in a rapid descent from a high altitude. True binocular vision, especially when travelling at a great speed, and rapid connexion between sight and action were so necessary, that in selecting pilots it was most important to ascertain that they were perfect in these respects. Very often it had been discovered that one eye was not used at all; such a man should not be allowed to enter the service. The troubles of low flying were not nearly so marked as of high flying (10,000 feet and over).

For the reduction of aviation dangers the first necessity was to have a set of trained doctors in contact with aviators. They would in the first place furnish the statistics and observations on which to build up the theory. The skilled medical officer could ascertain to what height an aviator might go safely, and to what height he might go with oxygen. Air medicine was so new a subject that it was not taught in the schools. Only a few were working at it, and the number engaged in regulating the admission of pilots was small. Another point was that medical men should be in close touch with aviators to keep an eye on them. High flying had a cumulative effect on the aviator. A man went up the first day and perhaps he was a little elated; much the same thing would happen for three or four days, but then he began to find he was not quite up to the mark; in other words he was getting stale. A superior officer wanted a man, and he asked a commander to send along one of his best men—it might be from a unit where the medical man knew nothing about air illnesses: hence might come disaster to the aviator. What was wanted was a medical man with some force of character who would say, in a case of this kind, to the general, "You must not send up that aviator; it is not safe." A medical man of the air service ought to stand in much the same relation to the men as the athletic trainer to those he trained. If this work were done properly, double the number of doctors at present at aerodromes would be needed. There were also what might be termed "air diseases." One was distension of the intestine by gas, probably on account of the diminution in the air pressure. It caused pain and vomiting, but recovery followed a few days' rest.

These were the chief reasons for a medical air service, the members of which should devote themselves wholeheartedly and permanently, or quasi-permanently, to this work. The army and the navy between them apportioned a certain number of medical officers to the aerodromes to attend to the flying club, and the new service ought to

take over the whole of the men doing that work in England, and thus get a nucleus for a service. This would cost the navy and army nothing in the way of men. The service should also get its share of the new men, including men too old for conscription, but keen to do this work. Sir Watson Cheyne said he did not like putting a money value on an aviator's life, but an airman was reckoned to cost the country about £900, and his machine roughly about £4,000. If an aviator were killed and his machine were wrecked, there was a loss, roughly, of about £5,000. If one hundred lives and machines could be saved in the course of a year, the State would save half a million of money, and that would pay for the expense of the whole air medical service. He did not think, however, that expense ought to have anything to do with the matter. He regretted that a completely separate air service was not proposed, but felt it best to accept the compromise under which members of the other services were nominated on the Administrative Committee. It obviated further delay, and medical men would be in training, which was the main essential; after the war there must be a separate air medical service.

In the course of the debate Sir Hamar Greenwood said he was sorry that Sir Watson Cheyne, with a unanimous committee of distinguished men behind him, had not stood to his demand for a completely separate medical service; and Major David Davies expressed the same regret. The advisory committee of medical men appointed by the Air Board reported quickly, but apparently their report did not meet the views of the Directors-General of the army and of the naval medical services. The result had been a delay of two months. It was a slur on the members of the committee to have asked them to spend a great deal of time and trouble in preparing this report, and then to have turned it down. There was another example of the same kind of procedure in regard to the report of the committee sent to France to inquire into the arrangements of the Royal Army Medical Corps there. That report was sent in, he believed, five months ago; so far as he understood it was still being considered by the Army Council, and no steps had been taken to carry out the recommendations. What usually happened was that these reports were put on one side and a new committee was set up, which proceeded to consider the whole matter afresh in the hope that a report more in accordance with the views of the permanent officials would be produced.

Major Baird, in replying to the criticisms, said that at the request of the Director-General of Military Aeronautics military medical authorities had been working on special lines in regard to the Royal Flying Corps. The officers were now examined by a special medical board before they were sent to France. Another staff was engaged in the medical examination of officers suffering from disabilities caused by flying. A special type of hospital had been set apart for the treatment of members of the flying force, both military and naval; in addition, a Royal Flying Corps Hospital, maintained by private subscription, had been at work for more than two years. It provided accommodation for seventy serious cases, and for more than 100 convalescents. He added, in reply to questions, that candidates for service as air pilots were rigorously examined by a special medical board in London, and that the administrator of the air medical service would not be on the Air Council, but would have direct access to the Secretary of State.

Army Estimates.

The Work of the Army Medical Service.

In his speech introducing the Army Estimates, on February 20th, Mr. Macpherson paid warm tribute to the work of the Royal Army Medical Corps. Having recalled figures as to the satisfactory conditions in France as compared with the experience of armies in the past, Mr. Macpherson said that owing to climatic reasons the conditions in Salonica were not so satisfactory. But the amount of sickness in the Salonica army had in 1917 been reduced to two-thirds of what it was in 1916, and the death-rate in 1917 had been reduced to one-third what it was in 1916. Having remarked that the success and gallantry of the Army Medical Service had given it a place in the army which it had never had before, the Minister said it had now been arranged that the term "lieutenant-general" or "major-general" should be applicable to a surgeon-general, and in future a general in the Royal Army Medical Corps will be known as lieutenant-general or major-general "A" or "B," surgeon-general to the forces.

Sir Alfred Keogh.

No one had been more responsible for the success of this branch of the service than Sir Alfred Keogh, who, coming

forward at the beginning of the war, after a brilliant career, had assumed control of the service he had so long admired. He would soon go back to the scientific work which he loved. Mr. Macpherson therefore took this opportunity publicly, on behalf of the Army Council and the army as a whole, and, indeed, on behalf of the whole of the people in this country who had friends in the army, to acknowledge the magnificent work of Sir Alfred Keogh during three and a half years of strenuous toil.

Mr. H. J. Tennant (Under Secretary of State for War 1912-16) reminded the House that in the Napoleonic campaigns, of the dead only 3 per cent. died of wounds and 97 per cent. of disease. The nation, reflecting upon the extraordinary alteration that had taken place in the present campaign, would be really grateful to those who planned and organized the wonderful organization by which so many lives had been saved. There was no doubt that the master hand and the master mind in that organization was Sir Alfred Keogh. When he came back to the War Office to administer the medical services he brought judgement, skill, and prudence, for which all were most grateful; he had laboured with tirelessness, unceasingly and devotedly, for three and a half years to make the scheme as perfect as it was. Mr. Tennant said that he had had the honour of conferring with Sir Alfred Keogh during a time more pregnant perhaps with possibilities of failure or success than any other period during the war, and looked upon it not only as a privilege, but as a cogent and pleasing duty, to record his warm appreciation of Sir Alfred Keogh's services to the State, as well as his great admiration for him as a man.

The Place of Civilian Doctors in the Army.

On February 25th Mr. Walter Roch raised questions as to the use now being made of civilian doctors in the army. A very large proportion of the purely administrative posts in the army to-day were held by the old officers of the R.A.M.C. Of the civilian doctors with wide experience gained in the hospitals and the various branches of the profession some might well be appointed to such posts. Speaking of the distribution of distinctions, Mr. Roch said that while one of every two of the regular army medical officers had been decorated, only one in fifty of the fourteen thousand civilian doctors had been decorated. The sacrifices of these civilian doctors had been very great, and such as to alter their whole scheme of life: many who had given up substantial practices were now undergoing great hardships. He had received a letter from a friend in Salonica, a surgeon and a Territorial officer, who since the beginning of the war had remained a captain; he took his orders from his army medical officer as to what operations should or should not be performed although he had a large surgical experience which would have enabled him to suggest the kind of operation which should be adopted. Small use was made of some of the foremost operators in the profession. He had numerous letters showing that eminent civilian medical men had never performed any operation at all. It seemed ludicrous that the War Office should have at its disposal such men who were now almost wasting their time, for they were not carrying out those operations they were so eminently fit to perform. He wished that these civilian doctors and surgeons were formed into a staff for the base hospitals, giving them liberty to choose the men—none knew better than themselves—who were best qualified to carry out the work which falls to the civilian medical officer with the army. After mentioning some instances of specialists whose services had not been utilized, he said that he did not suggest that these things were general—though he was told they were—but they left the impression that the barrier which existed between the old officers of the Royal Army Medical Corps and the body of civilian medical officers was very real. The War Office should again consider the restoration of the old Advisory Medical Board, and make use of the civilian medical man with his great knowledge, bringing into the board, if necessary, representatives of the Canadians, the South Africans, the Australians, and perhaps the Indian Medical Service.

Mr. Macpherson, in his reply, said he hoped that Mr. Roch would now have felt assured that the distinctions which existed in the past between civilian doctors and doctors of the Royal Army Medical Corps were dying away. He understood that the reform which had come into existence made all distinctions a thing of the past. It was natural that more decorations had been given to men in the Royal Army Medical Corps than to civilian doctors, because the first went out at the very beginning of the war. Mr. Roch, interpolating, said he was taking comparisons for three years. Mr. Macpherson replied that he did not think that affected his argument much. Most of these civilian doctors were kept at home doing part-time

work. They were carrying on their own practices and also doing civil work in hospital, and while the nation was very grateful to them for their part-time service, he could quite imagine it did not give them the opportunity for decoration which was given to the Royal Army Medical Corps, who were established officers, who had been bearing the brunt of work at the front and in the trenches.

The Advisory Medical Board, Mr. Macpherson said, had not, so far as he knew, met at any time during the war as a board, but the Director-General of the Army Medical Service had been in constant communication with either one or other of the members of that board, and had received invaluable advice from them. Mr. Macpherson said he should not like to see the able surgeons in administrative posts, for it was better that they should do their own specially skilled work. The best work for them was not administrative, but in the hospital dealing with the major operations and all the worst cases that arose.

Brothels in France.

During the debate references were made to the action of the British military authorities in France with regard to regulated brothels. Mr. Lees-Smith observed that in France there was a system of licensed regulated brothels, and there were many in towns largely occupied by British troops. Mr. Macpherson had said, in reply to various questions, that these places were under the control of the French civil authorities, and that the War Office had no jurisdiction over those authorities, but it had jurisdiction over the British soldier. Why did the British military authorities leave these places within bounds when the Americans in the towns they controlled had put them out of bounds? Similar inquiries were made by Mr. Roch. Mr. Macpherson, in his reply, said that there was no truth in the statement that the British military authorities had either requested the French military authorities to keep up these institutions or indeed connived at their maintenance. The view of the army was that the question was one entirely for the French civil authorities. While in this country there might be no hesitation in taking a certain action, yet in a country allied to us and on the most friendly terms with us, the army was in an extremely difficult position, and it could not ride rough-shod over arrangements which were accepted as part and parcel of the life of the country. It was true that certain estaminets and cafés had been put out of bounds for a specific purpose—namely, to prevent disorder. He promised to make further inquiries as to American arrangements. At the same time the alternative seemed to be, on the one hand, the danger of tolerating houses, and, on the other, that of soldiers meeting in the public streets with women who made their living in that way who were unregistered, and would not give the men associated with them the security a registered woman might give.

Venereal Disease.—On February 5th, at the request of the Under Secretary of State for War, Mr. Peto postponed a further question asking for particulars as to the number of men suffering from venereal disease who passed through army hospitals in 1917, the number on the sick list in France and in this country on any one day in the four quarters of 1917, and whether the Army Council intended to substitute for the War Office letter dated March 18th, 1916, instructions to medical officers to use every measure to prevent waste of man power in the army from this source. He also inquired whether it was true that there were between 40,000 and 50,000 men always in hospital for venereal disease. Mr. Macpherson has since informed Mr. Peto that the number of soldiers admitted to all hospitals in the United Kingdom in 1917 for all forms of venereal disease was 54,884. The number of soldiers in all hospitals in the United Kingdom suffering from venereal disease was:

On February 28th, 1917	9,053
On April 30th, 1917	8,045
On July 31st, 1917	7,392
On September 9th, 1917	3,674

Medical Men of Allied Nationalities.—In reply to a question by Sir William Collins, Mr. Macpherson stated that medical men of allied nationality, though holding qualifications in their own countries, were not eligible for substantive commissions in the Royal Army Medical Corps. They might, however, be employed by the War Office as was the case with American surgeons.

Medical Department, Ministry of Pensions.—In reply to Mr. Alder, Mr. Hodges (the Minister of Pensions) said that Sir John Collie is a whole-time officer of the Ministry of Pensions.

THE WAR.

INJURIES OF THE VERTEBRAL VESSELS.

PROFESSOR HERMANN KÜTTNER has written an elaborate account of injuries of the vertebral vessels in the neck.¹ Of the fifty-one cases mentioned, forty-four are from earlier records, whilst seven had come under his own observation. Three patients survived operation, and two it is said made good recoveries.

Case 1.—The bullet had traversed the left side of the neck from the level of the cricoid cartilage to the second dorsal spinous process; both apertures had healed. A thrill, ceasing on compression of the carotid, could be felt in the lower part of the neck. The carotid artery was isolated with great difficulty in the dense cicatricial tissue, and found to be uninjured. Further tedious dissection of the transverse cervical, inferior thyroid, and vertebral arteries disclosed an aneurysm of the last named, communicating inferiorly with the vertebral vein. A ligature applied below the sac sensibly diminished the thrill, which, however, gradually became re-established. The upper part of the sac was tightly pressed against the vertebrae and the enlarged foramen of the sixth transverse process, and on incision it was found that its posterior wall was inseparably fused with the vertebrae, so that complete excision was impossible. The severe haemorrhage which followed was only partially arrested by ligature of the upper part of the sac and of the rigid collaterals opening on its hinder wall. Small fragments were therefore cut from the sterno-mastoid muscle and the cavity was plugged with these, and the bleeding stopped. The patient, it is said, made a good recovery.

Case 2.—The bullet had passed transversely through the hinder part of the neck in its upper third. The wounds healed completely, leaving the patient with a distressing murmur and a well-marked thrill near the left suboccipital region. The common carotid and its main branches were found to be normal, and on the assumption that a small arterio-venous aneurysm existed on some secondary branch of the external carotid, the vessel, together with the superior thyroid, lingual, and facial branches, was ligatured, and the thrill disappeared. Eleven months later the patient stated that the murmur had returned in its original intensity; and a thrill was then present in the suboccipital region, but not within the area of the occipital artery.

Case 3.—In this case haemorrhage from a wound to the right of the larynx, traced to a perforation of a large vein deep in the neck, occurred also into the right pleural cavity, and the patient died on the eleventh day.

Case 4.—Six months after receiving a bullet wound in the neck, which had healed, the patient suffered from a persistent murmur in the left half of the head, and there was a large pulsating tumour below the lobule of the left ear, in front of which the dilated and strongly pulsating carotid artery could be felt. This artery was not connected with the aneurysm. An incision was made into the sac large enough to permit of exploration with the finger, when respiration suddenly ceased, the pulse remaining good. Artificial respiration failed to restore the patient. It was found *post mortem* that the hinder wall of the aneurysm was formed by the third, fourth, and fifth cervical transverse processes and the deep muscles of the neck; superiorly the sac reached the level of the axis, and inferiorly to the fifth cervical vertebra. It communicated, through a small aperture, with the vertebral artery in the interval between the third and fourth transverse processes. From this point upwards the artery was closed by a firm thrombus, which was continued into the basilar and its branches and into the opposite vertebral artery for a short distance. It further extended into the circle of Willis and thence into the right internal carotid artery, which just above its origin had received a perforating wound, each aperture being connected with a small aneurysm. Both the sacs and the whole length of the internal carotid were filled with firm clot.

Case 5.—Eight days after a gunshot wound of the shoulder secondary haemorrhage suddenly occurred. The wound was traced up into the neck, disclosing an abscess and wound of the vertebral artery at the fourth and fifth transverse processes, which were comminuted. With considerable difficulty the artery was ligatured. The patient died a few hours later.

Case 6.—Secondary haemorrhage occurred from a suppurating grenade wound behind the left ear, received one week previously. The bleeding was traced to injury of the vertebral artery in its upper part, and excision of about 2 cm. of the arch of the atlas was necessary before the vessel could be ligatured. It was probable that the carotid artery also had been wounded. Death occurred one hour after the operation.

Case 7.—Haemorrhage following a gunshot wound of the left side of the neck was traced to the vertebral artery in its canal. Ligature at the site of injury being impossible the vessel was tied in the first part of its course. The patient made a good recovery.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Died on Service.

MAJOR W. AP S. J. GRAHAM, R.A.M.C.

Major Walter Ap Samuel James Graham, R.A.M.C., died on February 23rd, aged 54. He was the eldest son of the late General Sir James Graham, K.C.B., and was educated at St. Mary's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1888. After acting as house-physician, house-surgeon, and resident obstetrical officer at St. Mary's, he entered the R.A.M.C. as surgeon on January 31st, 1891, and became major on January 31st, 1903. He served in the Nile campaign of 1898, receiving the British and Egyptian medals.

CAPTAIN P. H. DELAMERE, R.A.M.C.

Captain Percy Herbert Delamere, R.A.M.C., died in the Military Hospital, Milton, Portsmouth, on February 23rd. He was the eldest son of the late Captain P. H. Delamere, of the 21st Royal Scots Fusiliers, and took the diplomas of L.R.C.S.I. in 1882, and L.R.C.P.I. in 1883. He served for many years in the Colonial Medical Service in Demerara, British Guiana. He took a temporary commission as lieutenant in the R.A.M.C. on April 14th, 1915, and was promoted to captain after a year's service.

Wounded.

Lieutenant P. A. O'Brien, R.A.M.C. (temporary).

DEATHS AMONG SONS OF MEDICAL MEN.

Amesbury, Frederick Cholmondeley Dering, Major Indian Army (retired), son of the late Surgeon-Major J. W. R. Amesbury, I.M.S., died at Warwick on February 7th, aged 55. He was born on October 4th, 1852, got his first commission from Sandhurst in the King's Own Yorkshire Light Infantry on August 25th, 1883, transferred into the Indian army, and spent most of his service in the 10th Jats, attaining the rank of major on August 25th, 1901, and retiring on August 25th, 1907. He rejoined at the beginning of the war, and was posted to a service battalion of the West Yorkshire Regiment, and subsequently transferred to charge of the infantry records at Warwick. His eldest son, Second Lieutenant Hugh R. Amesbury, Bedford Regiment, was killed on November 20th, 1917, aged 27. He had previously served in the Canadian forces.

Harold, John Bevan, Lieutenant Royal Field Artillery, attached Royal Flying Corps, eldest son of the late Dr. John Harold, of Harley Street, died of wounds, aged 23, on February 16th. He was educated at Beaumont College, Old Windsor, and at University College, Oxford, where he was studying medicine, when he got a commission in the Special Reserve R.F.A., on August 13th, 1914. He had served for two years in France with the R.F.A., and a year ago transferred to the R.F.C., gaining his pilot's certificate last August. He returned to the front in December. While photographing over the enemy lines he was attacked by two German machines, but succeeded in bringing back his aeroplane, though severely wounded. His younger brother, Midshipman Geoffrey Harold, was lost in H.M.S. *Hogue* in 1914.

Hope, Humphry Bryan Thomasson, Lieutenant Northamptonshire Regiment and Royal Flying Corps, younger son of the late W. Hodgkin Hope, surgeon dentist, of Wellingborough, reported missing on April 26th, 1917, after an aerial fight with six German aeroplanes, now presumed killed on that date, aged 20. He was educated at Wellingborough School and at the Royal Dental and Middlesex Hospitals, London, when he got a commission in the Northants Regiment in November, 1915.

NOTES.

TREATMENT OF NERVE-STRAINED SOLDIERS.

MR. MACPHERSON, in stating that eight institutions for the care of nerve-strained soldiers were already organized, gave the names of the medical officers as under:

Lieut.-Colonel Mott, Maudsley Section, 4th London General Hospital, S.E.

Major Rows, Red Cross Military Hospital, Maghull.

Major Worth, Springfield War Hospital, Upper Tooting, S.W.

Lieut.-Colonel Fox, 4th Southern General Hospital, Plymouth.

Major Hurst, Royal Victoria Hospital, Netley.

Major Mackenzie, Glen Lomond War Hospital, Fife.

Captain Culpin, 1st Southern General Hospital, Monrhull Section, Birmingham.

Captain Clements, Bradford War Hospital, "Ahraia Peel" Section.

The Distinguished Service Cross has been conferred upon Surgeon Alexander Frederick Richmond Wollaston, M.B., M.A., R.N.

For conspicuous devotion to duty and for his unfailing care of the sick and wounded during military operations in East Africa. During the operations in the Rufigi River Delta he voluntarily attended to the casualties of the Rufigi River Transport Service in addition to those of his own unit.

The Distinguished Service Medal has been awarded to 1st Class Subassistant Surgeons Abdol Majid and Wahidyar Khan, and 2nd Class Subassistant Surgeon Chintaman Gopal Gogale, all of the I.S.M.D.

England and Wales.

PROPOSED TRANSFER OF FUNCTIONS OF POOR LAW AUTHORITIES.

At the meeting of the London Panel Committee on February 26th a memorandum on the medical questions involved in the proposed transfer of functions of Poor Law authorities to public health authorities in London was discussed and, after some amendment, adopted. It recommended that whenever the transfer took place two distinct departments of the medical service should be established under the local authority, one dealing with public health questions, and the other with individual health questions, both preventive and curative, the two to work under a common central control. Every local authority should have two medical officers of equal status, one in charge of the sanitary, and the other of the clinical service. So far as the sanitary service was concerned, the best results would be obtained by increasing the number and maintaining the status and qualifications of the whole-time assistant medical officers of health. No general system of whole-time medical officers was likely to prove successful for the clinical service, and the Committee urged (as its only definite exception to the scheme for London as set out in the report of the Minister for Reconstruction) that medical service in the home should be given by a part-time service of general practitioners who should be remunerated by capitation grants. A part-time service of specialists and consultants should also be utilized to assist the general practitioners in connexion with domiciliary treatment. The memorandum also dealt with the question of administration, both of domiciliary and institutional services, and urged that the centralization of the administration of the "municipal hospitals" of the various boroughs in London was an essential feature of the scheme.

CENTRAL MIDWIVES BOARD.

At a penal session of the Board, held on February 20th, Sir Francis Champneys presiding, a number of charges of the usual kind were dealt with, and one midwife was struck off the roll. In one instance a midwife had inserted an advertisement offering "twilight sleep" treatment, and worded in an ambiguous manner. No mention was made that the treatment would be administered by a medical man. The Board agreed to censure the midwife and exact an undertaking that in any future advertisements there should be a clear statement that the administration of the treatment would be conducted by a doctor.

At the monthly meeting, on February 21st, the Secretary announced that the following bodies had respectively elected as their representatives on the Council:—*Royal College of Physicians*: Sir Francis Champneys, Bt., M.D. *The Privy Council*: The Lady Mabelle Egerton. *Society of Apothecaries*: Dr. A. H. W. Ayling. *Incorporated Midwives Institute*: Dr. J. S. Fairbairn. *Queen Victoria's Jubilee Institute for Nurses*: Miss Rosalind Paget. In reply to a communication from Dr. Janet Lane-Clayton, Dean of the Household and Social Science Department, King's College for Women, with regard to the scheme for constituting a central council for the physical welfare of women and children, it was decided to appoint the Chairman and Miss Paget as the Board's representatives on the Provisional Executive Committee. The M.O.H. for the county of Durham had forwarded a copy of the county council's scheme for providing trained midwives and medical assistance for them within the county. The Board expressed its approval of the scheme. Consequent on the establishment of a Central Midwives Board for Ireland, with power to prescribe rules for training and to hold examinations, the Board decided to give notice to all approved institutions, lecturers, and teachers in Ireland that its approval will be withdrawn from March 31st next. The Chairman moved, in pursuance of notice duly given—

That having regard to the urgent necessity of securing the reciprocal treatment of midwives certified in other parts of His Majesty's dominions and of otherwise bringing into harmony the laws governing the practice of midwifery in the different parts of Great Britain, the Lord President of the Council be requested to introduce into Parliament as soon as may be a bill to amend the Midwives Act, 1902, by enlarging the scope of the powers of the Central Midwives Board on the general lines laid down by the Midwives (No. 2) Bill, 1910, and recently adopted in the Acts for Scotland and Ireland.

Scotland.

A DEPUTATION, representing the county council and district of Lanarkshire, had an interview on February 22nd with the Secretary for Scotland in order to express to him their views on the administration of public health services, with particular reference to matters being discussed in connexion with the proposal to establish a Ministry of Health.

INSANITY AND THE WAR.

In his report as physician-superintendent of the Glasgow Royal Infirmary, presented to the annual general meeting on February 21st, Dr. Oswald said that among soldiers exposed to its dangers the war might be producing some new forms of nervous and mental disease, but for these ample provision was being made. In those with a tendency to such illnesses the war might bring about a condition which otherwise would not manifest itself. The prosperity enjoyed by the working classes with the restrictions on alcoholic excess, taken along with the absorbing interest, to the exclusion of all else, of the war and its problems, made for a decrease, not an increase, of lunacy. The number of cases noted as due to alcohol was the smallest recorded for many years, while those due to syphilis showed an increase. Alluding to the establishment of the scholarship for research, Dr. Oswald said it was the first of its kind in Scotland, if not in Great Britain, and its institution marked a definite advance. Glasgow was now in the unique position among university cities in this country in possessing an endowed lectureship in mental disorders (St. Mungo's College) and an endowed scholarship for research into their causes.

Correspondence.

THE TREATMENT OF WOUNDS BY FLAVINE.

SIR,—I have read with interest the article by Colonel E. M. Pilcher and Lieut.-Colonel A. J. Hull which appears in the *BRITISH MEDICAL JOURNAL* of February 9th.

The important practical question is not so much what is the absolute clinical value of flavine, but what is its *relative* value when compared with other substances which may be used under similar conditions. In other words, we must establish comparative standards. Some months ago I completed an investigation on these lines, and submitted a paper for publication which has not yet appeared in the press; but as I hope it may do so shortly, I do not wish to anticipate my results in detail, and my remarks must be condensed.

For over three years I have treated wounds extensively with gauze packs, so that I may claim a considerable experience in this method. In my investigation I employed flavine in the method from which its advocates claim for it the best results, that is, in the form of gauze packs wrung out in 1 in 1,000 solution. In control cases I used packs of plain sterile gauze, normal saline, boric lotion, weak biniodide solution, and cyanide gauze, none of which substances are at present fashionable in wound treatment, and I purposely avoided using hypochlorites or other agents for which special merit has been claimed. The general principles and details of treatment adopted in all cases were otherwise identical, and very careful observations were made. No substantial differences were observed between flavine and the other substances in regard to the control of sepsis and constitutional signs of toxæmia (any slight differences were on the whole adverse to flavine), but in regard to the processes of repair flavine proved definitely inferior to the others. That is to say, that I found flavine not only not an excellent wound dressing but *relatively* a bad one. All the phenomena which Colonel Pilcher and Lieut.-Colonel Hull have observed in their wards I am accustomed to see regularly follow adequate drainage and the use of gauze packs, irrespective of what substance may be in the latter.

In regard to the film, coagulum, or pellicle which forms in flavine cases, my experience was that it appeared (in varying amounts) in every case. My clinical observations led me to believe that it consisted partly of a fibrinous exudate, and partly of a superficial coagulation necrosis,

and this seems to be confirmed by histological reports which have since been published. If its appearance is due to the use of too strong a solution, as these authors suggest, then we must assume that the solution advocated by its chief supporters—that is, 1 in 1,000—is too strong. Its removal from the surface of the wound is by no means easy in every case, and that is what we would expect in view of its constitution.

It is very difficult to draw any deductions from the proportion of cases which reach the "difficult suture ideal" under any form of treatment, as the possibility of reaching it is dependent far more on the physical characteristics of the wound and the stage at which efficient surgical treatment is adopted, than upon what reagent is employed in the wound itself. Since the period of treatment in base hospitals in France has been increased, as it has been in the last twelve months, I have found that the number of cases reaching this country in which secondary suture is mechanically possible is much less than formerly, and that there is a corresponding increase in the number of cases mechanically suitable for skin-grafting—a procedure which is certainly not inferior to suture as an ideal standard. From the physical characters of the wound when first seen, I decide whether it is a suitable case for either of these measures. If so, I can almost invariably get it into a condition when, without the aid of any bacteriological examinations, I can say clinically that suture or skin-grafting may be safely attempted. I hesitate to state, without giving details, that my secondary sutures have been invariably successful, and that my skin grafts, by the special technique which I employ, show certainly over 95 per cent. of complete successes—the exact percentage I have not at present available—although I employ neither flavine nor hypochlorites at any stage of my preparatory treatment.—I am, etc.,

WILLIAM PEARSON, Major R.A.M.C.,
Surgical Specialist.
Chichester, Feb. 21th.

SANATORIUM TREATMENT OF THE TUBERCULOUS SOLDIER.

SIR,—Expert opinion of the recent discussion at the Medical Society of London seemed unanimous that the continued use of sanatorium treatment for other than incipient or early cases is useless from the economic or public point of view. The offer of sanatorium treatment, therefore, to tuberculous soldiers after their discharge from the army and after they are more or less damaged lives, is bound to give disappointing results. This, however, seems to be the scheme of the Ministry of Pensions, and the monetary provision for such men as will accept institutional treatment is generous. It would be a great saving of man power and of money if the army authorities overlooked the early diagnosis and treatment of tubercle before the men put off their khaki.

Some time ago I came home from Egypt in charge of a convoy of forty-eight tuberculous soldiers returned from the Egyptian Expeditionary Force. All these men had been before medical boards in India, Palestine, or Egypt prior to embarkation. Forty-four were cases of pulmonary tuberculosis; most were in a comparatively advanced stage; both lungs were generally affected, and in some all five lobes were involved; eighteen showed signs of cavitation and 88 per cent. had tubercle bacilli in the sputum. The average length of time they had spent in military hospitals prior to embarkation was six months. In 74 per cent. of the cases the disease was considered by the medical boards to have been not caused but aggravated by active service, ordinary military service, or climate. If the findings of the medical boards, therefore, are correct, these men must have had active or quiescent tuberculous foci before being drafted overseas. The home localities of these forty-eight men embraced Scotland, Ireland, Wales, and seventeen different English counties.

The discharged tuberculous soldier, apart from his economic loss to the State and his own family, is bound to be a steadily increasing danger as a focus of infection to the community, until an effort is made to catch and treat the early and curable cases and segregate the advanced and infectious cases.

Judging from what one reads in the American medical journals, the problem of the tuberculous soldier is being

tackled with great energy by the medical authorities of the U.S.A. army.—I am, etc.,

TEMPORARY COMMISSION, R.A.M.C.

ARMY MEDICAL RECORDS.

SIR,—Your article on army service records (February 16th) will not be received with enthusiasm by medical officers of hospitals in this country.

It is to be regretted that the "index card" does not make for simplification and does not reduce clerical work. It is, in fact, an addition of one army form and not a reduction of one. The medical case sheet remains, and will remain if "the Medical Research Committee views its disappearance with some apprehension."

The index card is badly conceived; its faults are obvious if compared with the "field medical card." In the latter it is recognized that the medical officers at the field ambulances, the casualty clearing stations, and the base hospitals are different individuals, and so they are each given a separate space. The index card, however, fails to recognize that when a patient enters a particular group of hospitals in this country he is similarly treated by different medical officers, almost invariably by at least two, and often many more. It is impossible to decide who is the particular medical officer to make the necessary entries. Your article states: "The card is taken to the ward and comes under the charge of the medical officer, whose duty it is to fill in the diagnosis, with notes, etc., . . . authenticated by his signature." If I may be permitted to continue the story, I should write, "the patient is later transferred to an auxiliary hospital, where a minor or major operation is performed, returns to the central hospital, and is discharged to furlough." According to your article the card has already been completed and authenticated. The example quoted is a very common occurrence: every medical officer can mention scores of more complicated cases.—I am, etc.,

February 25th.

PUZZLEB.

THE PAY OF SPECIAL RESERVE OFFICERS R.A.M.C.

SIR,—Many R.A.M.C. officers will welcome Dr. Spence's letter on the pay of Territorial R.A.M.C. officers, published in your issue of February 16th, p. 216.

Dr. Spence should have added that Special Reserve officers are suffering under the same injustice, and perhaps in a more aggravated form, as promotion in the Special Reserve is slower than in the Territorial Force. He did not point out that when wounded and in hospital Territorial and Special Reserve officers lose all their allowances while temporary commission officers retain their full pay. Needless to say the loss of allowances is a very serious matter to a married officer if he is in hospital for any length of time.—I am, etc.,

February 21st.

HARD UP.

PAYMENT OF MEDICAL OFFICERS OF AUXILIARY HOSPITALS.

SIR,—In the SUPPLEMENT of February 16th you state that the Central Medical War Committee is pressing the authorities for a payment of a uniform sum of 10s. a day in the same form and manner as obtain in the Aldershot Command. You also admit the variation in the amount and method of remuneration in different areas. Now, no doubt you are aware, for instance, that the rate of remuneration in this area (Eastern Command) is 4d. per day per occupied bed, with the proviso that the medical officer shall not receive more than £1 per day. The medical officers live often some distance—it may be miles—from their hospitals, and have to pay for petrol and the increased wear and tear along roads that materially shorten the life of their cars.

To talk of making a flat rate of 10s. a day is manifestly unfair to many medical officers. Probably the varied methods and amounts of remuneration in different areas were originally fixed with the knowledge of the different conditions obtaining in different areas.

We in this area have been working for some time at the rate of 4d. per day per occupied bed, with a maximum of £1 per day, and find the amount none too much, considering the time, responsibility, and the expenses attached

to the work, and in spite of the fact that this is a comparatively easy area to work. May I add that for the above remuneration the medical officer has to visit the hospital at least once a day, Sundays included? To earn £1 per day he must have at least sixty beds occupied every day. If he has more occupied beds than this, he only receives the £1 per day notwithstanding. If the Central Medical War Committee intends to press for only 10s. a day it will be acting adversely to the interests of the medical officers in, at any rate, this area—possibly in others; and in some cases men who are running small hospitals will gain at the expense of those who are putting in a great deal of time at larger hospitals.—I am, etc.,

W. H. CHESTERS,

Honorary Secretary, Bromley Local Medical War Committee.

Bromley, Feb. 24th.

Obituary.

F. M. SANDWITH, C.M.G., M.D., F.R.C.P.,

LATE CONSULTING PHYSICIAN, EASTERN MEDITERRANEAN FORCE.

Dr. F. M. SANDWITH died suddenly, on February 17th, at Bournemouth, where he had gone for the benefit of his health after serving for two years as consulting physician in Egypt to the Eastern Mediterranean Force with the temporary rank of colonel.

Fleming Mant Sandwith was born in 1853, the second son of Colonel J. W. F. Sandwith. He was educated at Charterhouse and St. Thomas's Hospital, and took the diploma of M.R.C.S. in 1876 and that of L.R.C.P.Lond. in the following year. In 1893 he graduated M.D.Durh., and became F.R.C.P. in 1900. He saw a great deal of service in various wars. He was an ambulance surgeon in the Turco-Serbian war of 1876, and in the Russo-Turkish campaign in 1877-8; he was present at the fighting at Shipka Pass, and served on Baker Pasha's staff during his retreat across the Rhodope Mountains. In 1883 he went to Egypt to combat a cholera epidemic, and acted as vice-director of the Public Health Department of the Egyptian Government until 1885. He was then appointed professor of medicine in the Egyptian Government Medical School, and physician to the Kasr-el-Niny Hospital, Cairo. In 1900 he became senior physician to the Imperial Yeomanry Hospital at Pretoria, and served throughout the South African war. He was the author of *Medical Diseases of Egypt and Egypt as a Winter Resort*, and when he settled in London maintained his keen interest in tropical diseases. He was lecturer on tropical diseases at St. Thomas's Hospital, and was a lecturer also in the London School of Tropical Medicine, as well as senior physician to the Albert Dock Hospital. He held the Chair of Gresham Professor of Physic in the City of London. He was a member of many medical societies at home and abroad; he was president of the Section of Tropical Medicine at the annual meeting of the British Medical Association in London in 1910, having been vice-president at Leicester in 1905. He delivered the Lettsomian Lectures at the Medical Society of London on dysentery in 1914, and wrote many papers on the prevention and treatment of tropical diseases. In the earlier part of the war he was physician to King George's Hospital. In 1916 he received the C.M.G. in recognition of his services in Egypt. He married the daughter of Dr. Humphrey Sandwith, of Kars, who survives him, with two sons—one a lieutenant in the navy, the other still a schoolboy—and two daughters, the elder of whom is married to Squadron Commander Maude, R.N.A.S.

The above is a brief account of Dr. Sandwith's medical career, but we would add a few words about "the man" rather than "the doctor." For those who really knew him there was a charm about his personality which greatly endeared him to his friends. Very quiet, almost reserved in manner, with a half-cynical pose which was much more assumed than real and which was relieved by a most delightful sense of humour, he was one of the kindest of men, always ready to help, saying little or nothing about it, and never grudging trouble in doing it. He had a wonderful power of sympathy and of looking at things from the point of view of those who sought his advice—a power which greatly added to his usefulness in the world.

His health latterly had not been good, and some time ago he underwent a severe operation, from which, however,

he made a good recovery. But he felt the strain of the last two years in Egypt, and the heat, which was more than usually intense, greatly taxed his strength. When he returned home about two months ago his friends could not fail to recognize that he was worn and jaded. He was still anxious to work, and his retirement from the army was a great disappointment to him; but he took it quietly with a smile, and in the true spirit of a soldier. He died gently in his sleep—a happy ending to a strenuous life.

Dr. JAMES WATT BLACK, consulting obstetric physician to Charing Cross Hospital, died at Crockham Hill Place, Edenbridge, on February 22nd. Dr. Black was born in 1840. He was the son of Mr. James Black, J.P., of Knock, Banffshire. He received the greater part of his professional education in Edinburgh, but studied also in Paris, Vienna, and Berlin. He obtained the diplomas of L.R.C.P. and L.R.C.S.Edin. in 1862, and graduated M.D.Edin. in the same year, being awarded the gold medal for his thesis; he had previously graduated in Arts at King's College, Aberdeen. In 1869 he became M.R.C.P.Lond., and was elected a Fellow in 1881. During the first five years after graduation he acted as private assistant to Sir James Y. Simpson, whose obstetrical and gynaecological works he subsequently edited. In 1869 Dr. Watt Black was appointed obstetric physician and lecturer at Charing Cross Hospital. In later years he acted as examiner in midwifery to the Royal College of Physicians, London, and the University of Oxford. Dr. Watt Black took an active part for many years in the work of the Obstetrical Society of London. He was president in 1891 and 1892, and his chief contribution to the Society's *Transactions* was on "Puerperal fever and septic poisoning." He was vice-president of the Section of Obstetric Medicine at the annual meetings of the British Medical Association in 1878 at Bath, and in 1895 in London. Beyond the edition of Sir James Y. Simpson's collected works he published little. During his years of active practice he gained a high reputation as a skilful and conscientious practitioner, and his genuine kindness won him many friends.

The death occurred on January 28th, at the age of 73, of Dr. JAMES ROBINSON, of Ulverston, one of the oldest active practitioners in the North of England. Dr. Robinson was a native of Ulverston, and studied medicine at Anderson's College and the University of Glasgow. After obtaining the qualifications of L.R.C.P. and L.R.C.S.Edin., and the L.S.A., in 1866, he served as house-surgeon to the Glasgow Royal Infirmary and Lying-in Hospital, and to the Carlisle Infirmary. Returning to Ulverston, he held for many years the post of medical officer to the local workhouse, and was honorary surgeon to the cottage hospital from its foundation in the early seventies. He took a keen interest in all local affairs and institutions, especially in the Volunteer movement. He was one of the earliest members of the Ulverston detachment, and retired with the rank of honorary surgeon-major. Of his six surviving children one is in medical practice at Gateshead.

On February 4th Dr. T. ARNOLD JOHNSTON died at his residence, Leicester, at the early age of 37 years. A native of Ulster, he was educated at Belfast and at Edinburgh University, where he had a brilliant career, gaining many scholastic distinctions. He graduated M.B., Ch.B.Edin. in 1907 and M.D. in 1910. After holding resident appointments at Edinburgh, Bradford, and Leicester, he started consulting practice in the last-named town, specializing in bacteriology. He was appointed on the honorary staff of the Royal Infirmary as pathologist, and later as assistant physician. In addition he was pathologist to the Borough Mental Hospital and to the 5th Northern General Hospital. Dr. Johnston fell ill immediately after his marriage in 1915, being the victim of an infection acquired in bacteriological work. After many months he apparently recovered and resumed work, but a chronic meningitis supervened, which eventually proved fatal. Intellectually gifted, he was cheerful and kindly, and very popular professionally and socially. His early death is deeply regretted by his colleagues in Leicester, and much sympathy is felt for his widow and for his mother.

A MEDICAL friend of the late Mr. W. H. Jalland, whose death was announced in the *JOURNAL* of February 16th, p. 217, sends a personal note in which he says that Mr. Jalland justly held the premier position as surgeon in York. He possessed a sound judgement: he took great pains; he kept himself well abreast of the times, and read the medical journals faithfully; he was loyal to the best traditions of the profession. In cases of difficulty his advice and support to the harassed practitioner were invaluable. In counsel he was always helpful, while his sound judgement was the main reason for his success; yet behind this was a conspicuous integrity of character which commanded respect. For nearly forty years the welfare of the York County Hospital was one of his chief interests. Many of the improvements were largely made at his suggestion—for example, the erection of the children's ward, the open-air balconies, and the incorporation of the Eye Institution. He freely gave of his ripe experience to many city institutions where his considered judgement was much valued, and besides his work for the British Medical Association he took an active interest in the York Medical Society, of which he was twice president. By his regular attendance and frequent contributions his influence upon the younger members was considerable. He never forgot the dignity of his calling and always upheld what is best and noblest in the profession. For years to come his tall commanding figure and his cheerful helpful personality will be greatly missed.

Deep regret is felt in Guernsey at the recent death of Dr. JOHN AIKMAN, Staff Surgeon-Colonel to the Lieutenant-Governor of the island, principal medical officer to the Royal Guernsey Militia, and past president of the Guernsey and Alderney Division of the British Medical Association. Dr. Aikman was born in Edinburgh in 1850; his father was the late Rev. Dr. Logan Aikman. After studying medicine in the University of Glasgow he graduated M.B. and C.M. with honours in 1871, and proceeded M.D. three years later. Having held house appointments at the Glasgow Maternity Hospital and the Glasgow Royal Infirmary, he served for a short time as assistant medical officer to the Metropolitan Asylums Board; he then went to Guernsey, where he practised for more than forty years. For some time he was surgeon to St. Peter Port Hospital, and he was surgeon to the Victoria Cottage Hospital, Guernsey, at the time of his death. Dr. Aikman was devoted to his profession and to his patients, and was held in the highest regard throughout the island. While shunning public life he had a great capacity for friendship, with a sympathetic charm of character. Much of his leisure was devoted to literature, which was his principal recreation; his published essays on a variety of general topics were much appreciated by his large circle of friends. The funeral, which was of a semi-military character, was attended by the Lieut.-Governor and many representatives of the military and civil sections of the community.

Universities and Colleges.

UNIVERSITY OF LEEDS.

At a private degree ceremony, held on February 19th, Miss E. E. Violet Glover was admitted to the degree of Doctor of Medicine. Miss Glover is the first woman to obtain the Doctorate of Medicine in the University of Leeds.

SOCIETY OF APOTHECARIES OF LONDON.

The following candidates have been approved in the subjects indicated:

SURGERY.—D. A. Dyer, M. J. Panthaky, C. E. Rice, J. J. Remers, J. L. Walker.
MEDICINE.—O. Halstead, E. A. Leak, C. E. Rice, T. T. Tiplady.
FORENSIC MEDICINE.—A. D. Collio, R. E. Jenkins, C. E. Rice, T. T. Tiplady.
MIDWIFERY.—I. De Wardt, M. Girgis, T. A. Jordan, G. L. Mitchell, C. E. Rice.

Section I.

Section II.

The diploma of the society has been granted to Messrs. I. De Wardt, E. A. Leak, J. Remers, and C. E. Rice.

Medical News.

DR. D. RUD CAMPBELL of Drybrook has been appointed to the Commission of the Peace for Gloucestershire.

THE Carmichael prize, value £100, of the Royal College of Surgeons in Ireland for the best essay on the state of the medical profession, has been awarded to Alderman J. C. McWalter of Dublin, Captain R.A.M.C.

DR. A. ASHKENNY, honorary secretary of the School Medical Service Group of the Society of Medical Officers of Health, having received a commission as temporary lieutenant R.A.M.C., his address is now V.D. Section, Connaught Hospital, Aldershot.

THE trustees of Columbia University have under consideration plans for the establishment of a large clinic for the benefit of patients who do not wish to be recipients of charity but cannot afford to pay the fees of a number of specialists.

A MEETING of the members of the Old Epsomian Club will be held at the office of Epsom College, 37, Soho Square, on Tuesday next at 4.30 p.m., when, in addition to ordinary business, the sum to be given to the Epsom College War Memorial Fund will be decided. As the list of addresses is believed to be erroneous notices will not be issued by post.

DR. E. NORDENSKIÖLD of Gothenburg, the famous explorer, was present at the annual meeting of the Danish Medico-Historical Society at Copenhagen on December 10th, 1917, when Dr. Carl Jul. Salomonsen was elected its president for the ensuing year, and Professor Vilh. Maar undertook to edit its bulletin. Professor H. Mygind read a paper on the hygiene of the private house at Pompeii.

IN a report presented to the London Education Committee on February 27th Dr. W. H. Hamer, school medical officer, called attention to the relation between overcrowding in air raid shelters and the increased spread of infectious diseases. During the autumn air raids rises in the incidence of certain infectious diseases, including measles and scarlet fever, corresponded with periods of special crowding.

DR. D. M. WILSON, honorary secretary, Cheadle and District, informs us that the Cheadle (Staffs) medical men holding appointments under the guardians of the poor and the rural district council applied for an increase in their salaries and emoluments to the extent of 25 per cent., plus 10 per cent. for travelling expenses, plus 5 per cent. for drugs. The guardians and district council refused the application, so that the medical men concerned decided to resign their offices, and their resignations have been accepted by the guardians and district council.

THE introduction of compulsory rationing and the discontinuance of the voluntary propaganda department has led the Food Controller to reorganize the food economy division of the Ministry hitherto conducted by Sir Arthur Yapp. It will now consist of four branches: Public services food consumption, National Kitchens, Public Catering, and an Educational Branch under the direction of Professor E. H. Starling, F.R.S. The co-ordination and control of the several departments will be exercised by a Food Survey Board, of which the directors of the several departments will be members, with Lieut.-Colonel A. G. Weigall, M.P., as chairman.

A SMALL pamphlet entitled *Weekly Meat Rations*, containing Taylor's tables for rapidly calculating the purchasing value of coupons from 1 to 24, has been issued by Messrs. Mathieson and Sons, 16, Copthall Avenue, E.C.2 (price 6d.). A general note on meat rations is followed by a set of tables showing the amount of money that may be spent on meat in each week if three coupons a head or any smaller number are used, and the weight of other meat foods which can be obtained with the fourth coupon, which cannot be used for buying butcher's meat. The pamphlet ought to be very useful to any housekeeper who will take the small pains necessary to understand it.

THE Health Department of Cincinnati has established a health centre in the city for the purpose of carrying out a programme which includes the prenatal care and education of expectant mothers; the examination of children under school age; school medical examination and follow-up work; the establishment of health leagues in schools; junior Red Cross work, including elementary hygiene, home care of the sick and first aid; better housing and improved sanitary conditions for the community; frequent inspection of bakeries, dairies, groceries, restaurants, barbers' shops. It is also proposed to establish a night clinic for working men should the need for such a service exist.

Letters, Notes, and Answers.

Authors desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are:

1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Articulate*, Westrand, London; telephone, 2631, Gerrard.
2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin.

The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES AND ANSWERS.

RAT-BITE FEVER.

DR. ALFRED C. COLES (York House, Poole Road, Bournemouth) says that in the course of an investigation on 100 rats in England he found nine harbouring the *Spirochaeta icterohaemorrhagiae* of infective jaundice, and one, the eighty-fourth rat from the country, contained the *Spirochaeta morsus muris*, which the Japanese observers have shown to be the cause of rat-bite fever. He has described his method in an illustrated paper shortly to appear in *Parasitology*. Dr. Coles desires the loan of a slide showing the Japanese spirochaete, and asks that any reader who meets with a case of rat-bite fever would send him an excised gland or a smear from an excised or punctured gland, and blood films from the seat of the rash or wound, both taken during the febrile attack.

FINGER CRACKS.

DR. F. S. D. HOGG (Rickmansworth) writes to suggest smearing the crack with a probe or pointed match dipped in pure carbolic acid. "I tried this as an experiment on myself some thirty years ago, and since then have used it with invariable good results on myself and some others. One application is usually sufficient. The carbolic should not be put on the skin surrounding the crack."

SYPHILIS AND STILLBIRTHS.

"SCOTTS" says that thirty-five years ago the finding *post mortem* of a red spot in the cartilage of the upper end of the femur in an infant was considered to be pathognomonic of syphilis, and asks whether this was observed by Professor Beattie in the series of stillborn infants examined by him (p. 232).

INHABITED FURNISHED HOUSES.

H. A. L. B. inquires whether an officer is compelled to pay (a) local rates, (b) income tax, and (c) inhabited house duty on a house "which has been closed for the past eighteen months, furniture remaining in the house."

If the amount of furniture is considerable, yes. The leading cases are, as regards local rates, *The Queen v. St. Pancras Borough Council* (2 Q.B.D. 583), and, as regards taxes, *Smith v. Dauncy* (20 T.L.R. 444). We may perhaps add that we have heard of, but cannot vouch for, cases in which rates and taxes have been passed by local authorities, either in whole or in part, where the furniture has simply been stored in one or two rooms instead of being left more or less *in situ*.

LETTERS, NOTES, ETC.

DR. R. W. LEFTWICH writes to say that Professor Best's conclusion that saccharin increases acidity is not new. It was noted in the sixth edition of his *Index of Symptoms*.

AN APPEAL.

We have received the following appeal:

May we appeal to the generosity of your readers on behalf of the wife and daughters of the late Mr. J. Kite, M.R.C.S., of Welwyn? Before his death, which occurred at the end of last year at the age of 76, he had been in failing health, mentally and physically, for some years, and for two years had been unable to practise. A kind-hearted man, of generous and easy-going disposition, he was, like others of the medical profession, singularly unbusiness-like, and often omitted to keep any record of his professional visits and to send in accounts. His life was not insured, and his family find themselves seriously burdened and handicapped by debts amounting to about one hundred pounds. Were these paid off they could start fair and ensure a reasonable livelihood. Mr. Kite

was a member of the British Medical Association, and we cannot but feel that many members would be willing to send a small contribution to help the family of a medical man who was universally esteemed and respected. Donations will be gratefully received and acknowledged by either of us—Arthur E. Giles, M.D., F.R.C.S., 10, Upper Wimpole Street, W., and Bridge Cottage, Welwyn; P. M. Wathen, M.A. (Rev.), The Rectory, Welwyn, Herts.

MALTHUSIANISM AND MORALITY.

MR. E. B. TURNER informs us, in reply to Dr. Binnie Dunlop's inquiry (February 23rd, p. 248), that his statement was founded on a large number of actual cases which had come to his own knowledge in the course of his practice, and also on definite statements from rescue workers, one of whom at the present time has several such cases under her observation.

VENEREAL DISEASES.

DR. E. H. SNELL (Coventry) writes: The statement furnished in the *JOURNAL* of February 16th by Mr. E. B. Turner appears to be well reasoned and cogent. Does it not seem to follow from the argument that the beneficent influences on society therein attributed to the existence of these diseases will disappear if these diseases can be successfully banished? And if so, that all steps taken to diminish the incidence of venereal disease tend also towards establishing a general condition of promiscuity and immorality? Do the continuance of properly organized national life and the sanctions of conduct really rest on such an insecure and rotten foundation?

DIET, STARCH, AND SUGAR.

DR. P. J. CAMMIDGE (London) writes: It may interest Dr. H. Campbell to know that the relation between an excess of sugar and diabetes has been very exhaustively investigated by Dr. Le Goff, of Paris, who read a paper on the subject at the Seventeenth International Congress of Medicine held in London in 1913. An article by Dr. Teizo Iwai on diabetes in Japan, in which the bearing of sugar and starchy foods on the etiology of the condition is thoroughly gone into, was translated by Dr. Le Goff and appeared in the *Archives de Médecine expérimentale et d'Anatomie pathologique* in 1916.

ON WRITING WITH THE LEFT HAND.

DR. RICHARD KERRY (Montreal) writes: Some time ago, following an accident which temporarily damaged my right wrist, I began to write with my left hand, and, with the view of making it useful for operative work, have continued to use it. I write with my left pretty much as with my right hand, though the writing, as you may see, is backhand. It should not be necessary to turn the paper at right angles to the ordinary position, and a little steady practice will develop a good deal of facility in using the hand.

THIRST AT SEA.

DR. T. F. J. BLACKER (Brighton) writes to express the opinion that the suggestion put forward under this head by two correspondents in the *JOURNAL* of February 16th, p. 220, is not practical. It could not, he thinks, be applied in the case of a boatload of men, women, and children adrift in mid-ocean. He raises also the question whether the water would not have to be raised to 37° C.

SPONTANEOUS HAEMORRHAGE INTO THE PERITONEAL CAVITY.

MR. W. PERCY BLUMER, F.R.C.S. (Edin.), late Honorary Surgeon to the Sunderland Royal Infirmary, writes: Dr. Billiard's case (February 23rd, p. 231) recalled to my mind a case I operated on about twenty years ago in the North of England. Writing from memory the facts were that a middle-aged man, a foreman in a railway goods yard, while attending to his usual duties was suddenly seized with acute pain in the appendix area. He was sent home by a conveyance and I saw him very shortly afterwards. I diagnosed acute appendicitis and recommended immediate operation. I was assisted in the operation by one of my hospital colleagues, who confirmed my diagnosis. Immediately on opening the abdomen in the usual line there was a rapid outpouring of blood. There was no time for making any exploratory examination; we immediately plugged the cavity with plain gauze and partially closed the wound. We left the wound undisturbed for forty-eight hours, when, with fear and trembling, we removed the plug very carefully. We were prepared for another outburst, but no further haemorrhage occurred, and the patient made a rapid and excellent recovery. As far as I know he is still living. As to arteriosclerosis I have no record, but this condition might help to solve an otherwise puzzling case.

HEMIPLEGIA FOLLOWING CEREBRO-SPINAL MENINGITIS.

DRS. C. J. COLEMAN (medical superintendent) and C. W. DIAS (resident medical officer), City Hospital, Lincoln, ask for information as to the pathology and prognosis of the following case, and advice as to any special treatment of the hemiplegia:

A man, aged 26, became ill with sore throat and vomiting on December 8th, 1917. On December 10th he was admitted to the City Hospital, Lincoln. A diagnosis of cerebro-spinal

meningitis was made. The temperature was 102°; retraction of the head, pain and stiffness of the neck, and Kernig's sign well marked, were present, but no diplopia or squint. Lumbar puncture was performed, 30 c.cm. of slightly turbid fluid drawn off, and 20 c.cm. of antimeningococcus serum injected intrathecally by the gravitation method. The specific meningococcus was found in the fluid drawn off. On December 14th the temperature was still raised, but the symptoms were much improved; 30 c.cm. of turbid fluid were removed by lumbar puncture. The patient continued to improve until December 21st, when he suddenly became unconscious but not comatose; there was also incontinence of urine and faeces, and paralysis of the left side of the body, including the face. Lumbar puncture was performed, and 30 c.cm. of turbid fluid under pressure removed. On the following day he was conscious and slightly better. On December 23rd he was comatose, breathing stercorously, with mucus in the throat, and more marked paralysis on the left side. On January 8th steady improvement was noted, but after that date symptoms of anaesthesia of the arm and paraesthesia of the leg developed. Throughout the illness, up to the date of the second seizure, insomnia was a marked feature, and did not respond to chloralamide, paraldehyde, or morphine. Headache of the violent type, restlessness, and delirium were absent throughout the illness.

KAPOK WOOL AS A DRESSING FOR WOUNDS.

JACQUES SILHOL strongly recommends the use of kapok wool as a dressing for wounds, as it has many advantages over cotton-wool (*Compt. rend. de l'Acad. des Sci.*, 1918, cxvii, p. 52). Kapok, or silk cotton, is a fine short-stapled wool, very abundant in Java especially. Its weight is only one-fourth or one-fifth that of cotton-wool; and it is remarkable for its impermeability to water, elasticity, and suppleness. In the treatment of wounds Silhol uses it either raw or after previous exposure to air. In irrigated wounds it absorbs not only their secretions but also such liquids as Dakin's. In dry wounds, without any other intervention, it absorbs the secretions of the wound, the blood corpuscles, and the microbes. Any pus that may be formed is remarkably poor in microbes. Microscopical examination shows that the wound contains few microbes, and that the fibres of the kapok dressing are very rich in microbes. Silhol states that, as far as his results have gone, he prefers very often the simple application of a kapok dressing to even a very well carried out irrigation by Dakin's fluid. Not only does kapok wool form an excellent covering and protection for wounds, but it is also a better packing substance for wound than cotton-wool.

HYDROPHOBIA FROM THE BITE OF A CAMEL.

In the *Review of Current Periodicals* by the staff of the Research Department of the Severance Union Medical College, Seoul, Korea (vol. ii, No. 6), there is a report by T. Neguchi, of a case of hydrophobia from the bite of a camel, which is published in the *Taiwan Igakukai Zasshi*. The patient was a keeper in the Zoological Gardens of Taihoku, Formosa, who on October 28th, 1916, was bitten on the right ankle by a camel imported from America. The wound was painful, but healed in a couple of weeks. Some time afterwards the camel died of a disease diagnosed at the *post-mortem* examination as pneumonia. On January 9th, 1917, the man noticed pharyngeal spasms on trying to drink; the other characteristic symptoms of acute hydrophobia followed, and he died on January 12th. Negri bodies were found in the brain, and the other findings were unmistakable. There was nothing in the camel indicating or even suggesting rabies, but the bars of its cage were so spaced that it would have been possible for a rabid dog or other animal to enter.

VOLUNTEER TRAINING CORPS.

"LIEUTENANT AND M.O. VOLUNTEER BATTALION," after nearly three and a half years of duty and attachment to a Volunteer battalion, finds himself in the same state of ignorance as our correspondent of last week. He has recently been gazetted lieutenant and M.O. (temporary), but has not learnt what the pay is, or whether it dates from the day of being gazetted or of mobilization. Paragraph 1, A.E.V. 4009 reads: The M.O. "performs such duties in connexion with his appointment as the C.O. may consider necessary." This notification our correspondent finds too vague and wide in scope. Our correspondent is informed that a R.A.M.C. officer must explain and teach how even the "first field dressing" is to be applied. At the same time, A.C.I. 1823 states that a M.O. may obtain a grant towards the expense of his outfit by attending at a R.A.M.C. depot and passing an examination. He asks how a single-handed, overworked general practitioner in the country is to do this. His expenses during the last three years have included the purchase of two uniforms and a rifle, expenditure on petrol in taking men to drills, and the examination of recruits at places many miles from his house at a fee of 1s. a head. There is no allowance for petrol or wear and tear of car. He calculates that, with his subscription to the V.T.C., the cost to him has been well over £50. At one time he gave first aid and ambulance lectures free, but the numbers attending dwindled and the lectures had to be abandoned. There was no authority to enforce discipline, though the contingent was no longer voluntary except in name.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

The following subscriptions to the Fund have been received during the week ending February 25th:

	£	s.	d.		£	s.	d.
Dr. Lewis McMillan	1	1	0	Mr. A. Chapman	0	10	0
Mr. J. W. Gamble	2	2	0	Dr. Frederick S. Palmer	2	2	0
Dr. H. Hay	1	1	0	Mr. W. H. Marshall	1	0	0
Carlton W. Jenkin				Mr. R. A. Scott	1	0	0
Oliver, R. A. M. C.	5	5	0	Dr. W. B. Drentham	1	1	0
Dr. R. Evershed	1	1	0	Dr. Chas. Slater	2	2	0
Dr. Cautley	5	5	0	Dr. Robert Harris	1	1	0
Dr. J. H. Ormrod	1	1	0	Dr. James Hudson	2	2	0
Dr. Black	1	1	0	Dr. S. Hamilton	1	1	0
Dr. C. B. Ker	1	1	0	Dr. E. H. Young	2	2	0

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Vieux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

TREATMENT OF WHOOPING-COUGH.

DR. ARTHUR J. MATHISON (Hornsey, N.) writes to recommend the treatment of whooping-cough by a mixture of ammonium bromide and thymol, thus combining an antispasmodic with an efficient internal antiseptic. "I used to add phenazone, and if I include the cases thus treated, I have a very large number indeed; but recently I have omitted it. I find that ammonium bromide and glycerin thymol co. (B.P.C.) with suitable flavouring—very much needed—form a mixture leaving little to be desired. Given early in the case, the 'whoop' may never occur, or be quite infrequent, while probably all cases are considerably modified by its exhibition. A suitable prescription for a child of 6 would be: Amm. bromid. gr. xli; glyce. thym. co. (B.P.C.) ʒiv; ext. glycyrrh. liq. ʒiv; aq. ad ʒvj. One tablespoonful three times a day."

THE CASE OF DR. J. HENDERSON BELL.

ON July 14th we briefly reported that Dr. John Henderson Bell of Chelsea had been convicted on two charges of wilfully attempting to produce a disease in two men belonging to H.M. Majesty's Forces, and sentenced to six months' hard labour for each of the two offences, the sentences to run concurrently. Leave of appeal was granted, and the appeal was heard on November 27th. The defendant, who had throughout strenuously protested his innocence, called witnesses to prove his past high character and qualifications. The conviction was, however, upheld, but the imprisonment with hard labour was reduced to imprisonment in the second division.

We have received a letter from the Rev. A. G. Pentreath, D.D., Rector of Adlerley, Market Drayton, and formerly senior chaplain to the forces at Malta, stating that he himself, and Dr. Bell's other friends as well as his patients, are convinced of his innocence, and consider him the victim of a miscarriage of justice. He appeals to the medical men in the United Kingdom to take an interest in the case, and states (1) Dr. Bell has always borne an unblemished and irreproachable character, and has been universally respected. (2) He has practised as a medical man for seventeen years; for two years he was resident at the Edinburgh Royal Infirmary; for nine months house-physician to the Brompton Hospital; and for three years assistant medical officer at Hounslow Hospital; and he had been successful in practice at Chelsea. (3) Some of the leading medical authorities in London have individually examined the facts from a medical point of view, and are unanimous in regarding Dr. Bell's behaviour in the supposed criminal action as perfectly usual and proper.

Dr. Pentreath offers to send a précis of the case to any medical man who will send a stamped addressed envelope to him at Adlerley Rectory, Market Drayton. We hope that many medical men will interest themselves in the matter and obtain the précis, for a perusal of the statement submitted to us appears to show that the evidence upon which Dr. Bell was convicted was lacking in cogency.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postea restante* letters addressed either in initials or numbers.

SUGGESTIONS FOR THE PREVENTION OF POST-OPERATIVE THROMBOSIS AND EMBOLISM.

BY

FREDERICK McCANN, M.D. EDIN., F.R.C.S. ENG.,
SURGEON TO THE SAMARITAN FREE HOSPITAL FOR WOMEN, LONDON.

THE spectre of death from embolism still haunts the path of the operating surgeon. These sudden surgical tragedies, although less numerous than in former times, still occur in the practice of surgeons—good, bad, and indifferent—in every country, after “clean and unclean cases,” after short operations and long operations, after easy operations or after those attended with complications, whether performed on the young or on the aged. The cause, closely linked as it is with that of thrombosis, is variously ascribed to the blood being infected with bacteria, to the recumbent posture, to the anatomical situation of the affected vein, and lastly, to the quality of the blood.

All these are no doubt contributory, or, in the language of the textbooks, “predisposing” causes. Is there not something more? Does the fault not lie in the technique employed? I believe it does, and that the chief fault is expressed by the one word “transfixion.”

There must be some common error in the practice of operative surgery to account for these fatalities, otherwise their number would ere now have been reduced to vanishing point. Some surgeons have had the courage to place them on record, others remain silent. Statistics have been furnished from the Mayo Clinic in Rochester, U.S.A., which give some idea of the frequency of post-operative thrombosis and embolism. Thus E. H. Beckman¹ writes that in 5,835 surgical operations the total number of cases of phlebitis was 16. He says:

Although we continually have a certain number of phlebitis cases following operation, we have not been able to determine any causative factor in this annoying complication. . . . We are often surprised to find a phlebitis develop in a patient who has otherwise had an ideal convalescence. In only one of the present series was there an infected wound.

Appendicectomy	1 left, 1 right
Appendicectomy, curettage and perineorrhaphy	1 left
Cholecystostomy, internal	Alexander
curettage	1 left
Drainage and pelvic abscess	1 left
Total abdominal hysterectomy	1 left, 1 right
Gastrectomy	1 left
Cholecystostomy and appendicectomy	1 left
Cholecystectomy	1 left
Kraske colostomy	1 left
Tube and ovary appendicectomy	1 left
Ovarian cyst	1 left
Mayo's operation for prolapse	1 left
Ventral hernia	1 right
Cholecystostomy	1 right
		12	4

Three-fourths of these cases of phlebitis were in the left femoral or internal saphenous veins and one-fourth in the right. None were double. This is about the usual proportion in our clinic.

L. B. Wilson² gives a record of all the cases of fatal post-operative embolism occurring in the Mayo Clinic during the years 1899–1911 inclusive.

During this period 63,573 major operations were performed, with 47 cases of fatal post-operative embolism. Autopsies were made in 41 of the fatal cases.

The fatalities from embolism represent 5 per cent. of the total number of deaths from all causes 864,—that is, 0.07 per cent.

	Deaths.
After 2,372 operations on blood vessels	2
3,266 operations on the thyroid	2
2,281 operations on the mouth	1
2,391 operations on the stomach and duodenum	3
4,507 operations on the gall bladder	9
389 operations on the small intestine	1
9,908 operations on the appendix	4
2,530 operations on the colon and rectum	5
4,501 operations for hernia	5
900 operations on the kidney	1
601 operations on the prostate	4
7,993 operations on the uterus, tubes, and ovaries	10

Of the 47 cases, 26 were males and 21 females the youngest 25 years and the oldest 72.

19 of the fatalities occurred within the first week; 21 occurred within the second week; 4 in the third week; and one each on the twenty-sixth, thirtieth, and sixty-fourth days.

In 36 cases the embolism was pulmonary, in 10 cerebral, and in 1 coronary.

In 28 of the 41 cases examined *post mortem* the primary thrombus was located in the field of operation or in the femoral veins: in 4 cases the emboli were probably cardiac; in 9 cases the seat of origin was not determined.

Such is the story to be elicited from a large series of operations. Gall bladder operations and operations on the female genitalia furnish the largest number of deaths—0.19 per cent. and 0.13 per cent. respectively. Disintegration of the blood corpuscles from toxic substances is held to explain the high percentage following operations on the gall bladder.

Although sepsis is a most important factor in causation, yet intravascular clotting apart from sepsis does occur.

Still, it is the improvement in surgical technique, especially in the direction of combating sepsis, which has helped to reduce the number of cases of post-operative thrombosis and embolism. Who can be sure that complete asepsis has been attained during an operation or the subsequent convalescence? It is assumed when all goes well, but it is not proven. Indeed, it is much more difficult to exclude the septic element in any consideration of this subject than many writers would have us believe. In spite of elaborate precautions post-operative thrombosis and embolism still remain.

Ten years ago a woman who had undergone vaginal hysterectomy for uterine cancer, when sitting up in bed twelve days after the operation suddenly fell back dead. Her death was due to pulmonary embolism. This was an operation done by the old method of transfixion and ligature of the broad ligaments, healing, as all these operations healed, with varying degrees of sepsis, typical conditions for the development of post-operative thrombosis and embolism.

Further, statistics favoured the view that thrombosis and embolism more frequently followed operation on the female genitalia than in other situations. This preponderance was explained by the nature of the tissue involved, but I came to the conclusion that the operative technique must also be at fault.

I therefore determined to give up transfixion and to operate anatomically, picking up vessels cleanly and ligaturing them without encompassing masses of tissue. The result has been that I have never had another case of post-operative embolism or thrombosis either in my private or hospital practice.

Dangers of Transfixion.

Let me now draw attention to the application of the method in abdominal and pelvic surgery.

“Never transfix a vascular area” should become a surgical axiom. By transfixion vessels are liable to be punctured and bleed either externally or into the tissues; the transfixing ligature is tied to arrest the bleeding, and the result may be that the ligature remains in the lumen of the vessel.

Now, if this ligature is of doubtful asepticity or becomes subsequently infected, the natural process of clotting in the vessel may be arrested, the clot liquefying and becoming detached in portions or in its entirety. I use the word “may,” for it is really remarkable that thrombosis and embolism are not more frequent. Although the diminution of sepsis has been a great factor in improving results, yet it is worthy of note that it is not the severe infections that are followed by these troublesome complications, but rather those of a milder type. If a vessel has been punctured the ligature should be withdrawn and the vessel clamped and tied after removal of the blood clot. Again, in the tying of blood vessels, even those of small size, it is surprising to witness the amount of “muscle” some surgeons put into this part of an operation. The object of a ligature is to approximate the coats of a vessel and to keep them in apposition, not to cut them. As the success of the modern abdominal surgeon depends so much on his capacity to tie and stitch properly, it is necessary for him to cultivate a delicacy of touch so that ligatures and sutures are nicely and accurately adjusted without undue constriction. He must further acquire the art of using thin material without breaking it, for the fault more frequently lies with the surgeon than with the material.

Pedicle needles have served their purpose and should be given up. The large sharp curved needle is a dangerous weapon. Round-bodied needles should alone be used within the abdominal cavity, and in order that they may be held easily I have had them made with the posterior half flat. The employment of the round-bodied needle constitutes a distinct advance in surgical technique. Its advantages are evidenced, for example, in stitching the uterus, where little or no bleeding results from the passage of the needle. Death from embolism has followed such a simple operation as utero-suspension. Was a cutting needle used?

There are certain situations in the abdomen where transfixion is frequently employed—namely, the broad ligaments, the omentum, and the mesentery.

The Broad Ligaments.—Transfixion of the broad ligaments is a most dangerous proceeding. These ligaments contain between their layers a venous plexus specially well developed in the presence of uterine new growths and liable to be injured by the transfixing needle. In this situation it is easy to operate anatomically, to open up the broad ligaments, and to tie the vessels separately with thin material. "Chunks" of tissue should not be left ligatured with flick material liable to cause post-operative pain and maybe thrombosis.

The Omentum.—I believe the method of ligaturing the omentum by transfixion and interlocking sutures, as generally taught and practised, to be dangerous and a cause of post-operative thrombosis and embolism. It may be argued that the needle can be passed through an avascular spot. Do all operators take this trouble? Vessels in the omentum should be caught with forceps and tied, the same technique being employed when a portion is excised.

The Mesentery.—Here, again, transfixion is dangerous, and it is easy where a portion of mesentery is excised to catch the bleeding points, and to tie them and to approximate the two edges by tying over forceps instead of stitching. Transfixing the mesentery of the appendix with a needle and puncturing vessels may easily lead to thrombosis and embolism. Deaths from this cause after a simple appendix operation are by no means so rare. The "patches of pneumonia" and localized pleurisy seen after this and other operations are most probably embolic in origin. Puncturing veins in the wall of the caecum may be another cause of thrombosis. The use of a small curved round-bodied needle, avoiding blood vessels, should prevent such an accident when covering the appendix stump.

Stomach and Intestine.—It is important also to avoid puncturing vessels in the walls of the stomach and intestine during gastric and intestinal operations. The extravasated blood in the bowel wall may easily become infected and break down.

Abdominal Wall.—Care exercised in making the incisions in the proper positions and respect for the anatomical arrangement of the structures will prevent accidents in this situation. The deep epigastric vessels may be injured unless sought for and avoided when making lateral incisions in the abdominal wall. If the injury is not discovered a troublesome haematoma may result. Moreover, in using through-and-through sutures it is better to employ a figure of 8 suture whose track can be seen and followed rather than to thrust a needle blindly into the abdominal wall, and puncture a vessel or vessels. Accurate haemostasis in the abdominal walls, as in all other situations, is most essential, so that no clots are left which may subsequently become infected.

Summary.

- (a) Do not transfix or puncture blood vessels.
- (b) Do not tie or stitch too tightly and cut into blood vessels.
- (c) Obtain accurate haemostasis, leaving no blood clots.

If by attention to improvements in technique these post-operative fatalities can be still further reduced, "tis a consummation devoutly to be wished." For this purpose neat, clean workmanship, founded on sound anatomical knowledge, is required. There is still scope for the surgical artist.

MYOMECTOMY OR HYSTERECTOMY.

BY

VICTOR BONNEY, M.S., M.D., B.Sc.LOND.,
F.R.C.S.ENG.,

ASSISTANT GYNAECOLOGICAL SURGEON, MIDDLESEX HOSPITAL, ETC.

In the treatment of uterine fibroids myomectomy has had a very limited application as compared with hysterectomy. The positive indications for the former as against the latter operation have been a single tumour in a patient under 40 years of age either pedunculated, or at least not deeply embedded in the uterus, and not giving rise to excessive menstrual bleeding. It is now, however, in most cases possible, and I hold in many cases proper, to carry out the conservative operation though all these criteria are traversed.

The drawbacks that have been urged against removing the tumour or tumours and leaving the uterus are, first, that where the leading symptom is menorrhagia the haemorrhage may continue after the operation; secondly, that other tumours may arise either *de novo* or from overlooked seedlings; thirdly, that the likelihood of pregnancy in the conserved uterus is small, and that in the event of its happening the uterine scar may give way; and, fourthly, that the operation is frequently more difficult than hysterectomy while its risk is at least as great and often greater.

There are, of course, certain cases in which the propriety of removing the uterus is in no doubt: elderly women with large and multiple tumours; cases in which the anaemia is so extreme that any further loss of blood, even the amount of a normal menstrual period, is undesirable; inflamed or degenerate tumours, or large tumours growing in the supravaginal cervix. But besides these there is a considerable class of relatively young patients who, having fibroids in the womb, seek advice on account of menorrhagia, dysmenorrhoea, or abdomino-pelvic pain. It is in this type of case that myomectomy is artistry and hysterectomy crudity.

Let us examine the drawbacks that have been alleged against myomectomy and see if they are as cogent to-day.

CONTINUANCE OF MENORRHAGIA.

If excessive menstrual loss continues after myomectomy, it is due either (a) to a small submucous fibroid missed at the operation; (b) to endometrial thickening; (c) to the fact that the uterus has remained much hypertrophied although all the tumours have been removed; or (d) to a degenerate condition of the uterine wall.

(a) *A Missed Submucous Fibroid.*—It is easily possible to miss a small submucous fibroid, say the size of a pea, if the uterine cavity is not opened and inspected in the course of the operation, for so diminutive a tumour is with difficulty felt through the uterine wall. Hence the surgeon should as a routine open the cavity in most cases, and should make it an invariable rule to do so in every one where menorrhagia is complained of. I have frequently detected and removed in this way a little nodule which, if overlooked, would have defeated the whole object of the operation. The opening of the cavity in an uninfected case (and in none other should myomectomy be attempted) adds no risk to the operation.

(b) *Endometrial Thickening.*—In certain cases of fibroids diffuse thickening of the endometrium is present, whilst in others a local overgrowth in the form of a mucous polypus exists. Both abnormalities, if not dealt with, will maintain haemorrhage after the operation. An opening into the uterine cavity discloses them. Curettage is far more efficiently performed by this route than *via* the cervix, and a sharp scoop is the best instrument to use. A mucous polypus should be similarly blated, special attention being paid to the cornua. On several occasions I have found and removed a polypus situated in one of these recesses.

(c) *Hypertrophy of the Uterus.*—With all interstitial and submucous fibroids of any size hypertrophy of the uterus enclosing them necessarily coexists. The condition is, indeed, in this particular exactly analogous to pregnancy. Involution takes place after myomectomy just as it does after labour, but is more apt to be incomplete, and such subinvolution will cause menorrhagia to persist. It is necessary, therefore, in these cases not merely to remove the tumours but to trim down the uterus to a reasonable

size. This is done by cutting away the redundant capsule of hypertrophied muscle tissue or even a segment of the uterine wall down to and including part of the mucosa.

(d) *Degeneration of the Uterine Wall.*—The degenerative states of the uterine wall included under the term "fibrosis" may coexist with fibroids, and in such cases hysterectomy should be performed, not myomectomy. The conjunction, however, is a rare one, the uterine musculature over a fibroid being, as a rule, conspicuously well developed. A smooth, flabby appearance of the uterine wall in a case marked by menorrhagia, especially if there is no enlargement of the cavity, suggests that "fibrosis" is the cause of the haemorrhage rather than the fibroids, and should determine the removal of the uterus.

RECURRENCE OF TUMOURS.

That new fibroids do occasionally form after myomectomy is undeniable, but I believe that the large majority of reappearances have their origin in small tumours overlooked at the time of the operation, for the more thoroughly it is performed the rarer are such apparent recurrences. Only on one occasion can I remember having to remove the uterus subsequently on this account.

FUTURE PREGNANCY.

Noble, from an investigation of a large number of cases of myomectomy, stated that only 10 per cent. conceived after the operation.

Such general figures must not, however, be taken at their face value; for many of the patients are over 40, and the bulk of them over 35, whilst a good proportion are unmarried. Moreover, it is undoubted that the larger number of myomectomies are performed either on unmarried or sterile married women; on the first group in order to leave them not less fit for marriage, and on the second so as to maintain intact their capability for child-bearing in so far as they may be capable. Both these groups are relatively infertile. On the other hand, the fact that a woman has already borne children frequently determines the removal of the uterus, on the ground that she has had children and does not want any more. If the present practice was reversed, and myomectomy was more particularly performed on women of proved fertility, a much larger number of pregnancies would follow the operation than at present obtains.

The fear that the uterus after myomectomy will not stand the strain of pregnancy is groundless. There is probably no tissue in the body that heals so perfectly as the uterine muscle. I have had several opportunities now of viewing through an abdominal incision the after-results of this operation, and on no occasion could a trace be seen of the incisions in the uterine wall. This is in keeping with what one finds when performing Caesarean section on a woman who has previously been delivered through the abdomen.

Some years ago a patient was sent to me for the purpose of hysterectomy on account of large fibroids complicated by pregnancy. I tidied her through till term and then delivered her *via* the abdomen, not only of a fine child, but of five large fibroids as well, varying in size from a melon to an orange. The tumours were deeply embedded and the uterine cavity was opened altogether in three places. A year later she again became pregnant, and at her request I repeated the Caesarean section when she reached term. I could find no trace of my six previous incisions, the uterus being absolutely normal.

No time is so favourable for removal of a fibroid as immediately after the uterus has been delivered by Caesarean section, for the retractile and supple state of the uterine wall miniuizes the haemorrhage and makes suturing particularly easy.

In the operation of utriculoplasty a wedge-shaped portion of the uterus is excised and the lessened organ sutured, with the object of reducing the "menstrual area." The first patient on whom I performed this operation conceived three times subsequently, and on each occasion delivery by the vagina was successfully accomplished, a fact which strikingly illustrates the reparative power of the uterine wall.

THE RISK OF MYOMECTOMY AS COMPARED WITH HYSTERECTOMY.

The risk specially attaching to myomectomy as compared with hysterectomy is haemorrhage either during or

after the operation. There can be no question that the amount of blood lost during an extensive enucleation is considerably more than would be the case if the uterus was removed with the fibroids. Nevertheless, by correct technique the amount can be kept well within the limits of safety. The tumours should be enucleated, and the beds from which they came obliterated by suture one at a time. There should be no delay in inserting the interrupted mattress sutures that effect haemostasis, and if these are insufficient a continuous mattress suture should be inserted between the interrupted mattress sutures and the continuous superficial suture that approximates the peritoneal coat. The whole of the proceedings should be carried through quickly. Where the uterus is very vascular the ovarian vessels should be temporarily clamped with ring forceps, and in exceptional cases the uterine vessels may be similarly controlled.

A much more important risk to guard against than immediate bleeding is post-operative oozing from the uterine incisions. If this occurs not only is convalescence rendered febrile, but there is a very definite danger of a coil of intestine adhering to the clot-covered uterus and causing intestinal obstruction. This, the chief danger of myomectomy, can be prevented, first, by ensuring complete haemostasis before closing the abdominal wound; secondly, by whenever possible incising the uterus through its *anterior wall* so that the suture line presents towards the bladder instead of towards the intestines; and thirdly, by (in some cases) ventrosuspending the uterus to the anterior abdominal wall along the line of the uterine incision. Ventrosuspension has also this advantage, that it prevents the diminished organ from retroverting, which it is very apt to do after the fibroids have been removed. In many instances retroversion by the weight or pressure of the tumours is already present, and should be corrected by shortening the round ligaments, or, in the event of additional defence against post-operative oozing from an anterior incision being required, by ventrosuspension.

If the precautions thus detailed be taken the average risk of myomectomy is probably about the same as hysterectomy under corresponding circumstances. There are certain cases, still within the justifiable limits of myomectomy, where, on account of the size and multiplicity of the tumours, the risk is somewhat greater. In such the pros and cons of the alternative operations must be carefully weighed, the surgeon always reserving to himself the right of final judgement on the operating table.

THE WORTH OF THE CONSERVED UTERUS.

Removal of the uterus, if the ovaries are conserved, does not produce a climacteric, though, in the opinion of some, it tends to accelerate its normal advent; but in certain women the disappearance of the monthly loss does seem to produce congestive sensations, less in degree but similar to the "flushings" that mark "the change."

Removal of the uterine body alone only unfits a woman for marriage in so far as it renders her absolutely infertile, but total hysterectomy has the disadvantage of removing what, in some individuals, is an erotogenic zone, namely, the vaginal cervix.

The conceptional value of the uterus in women still of childbearing age who have grown fibroids is less than that of similarly aged normal women even after the fibroids have been removed, because the agent, whatever it be, that makes for myomatous growth also makes for sterility. The actual comparative ratio is, however, not determinable on account of the reasons previously given.

Apart, however, from its physical value the womb has for most women a sentimental value, which, however illogical, cannot be lightly dismissed; and amongst patients on whom hysterectomy has been performed there are probably more than the surgeon thinks at the back of whose minds dwells abiding regret and rebellion against fate.

CONCLUSION.

The outcome of these considerations and the experience on which they are founded has convinced me that the practice of myomectomy as an alternative to hysterectomy should be considerably extended. I now frequently perform the conservative operation with complete success where a few years ago I should have removed the uterus.

When the tumours are small or of moderate size, the proceeding can be carried out very well through a

transverse incision across the pubic hair field. This is a great advantage in relatively young women, especially if unmarried, for it leaves no visible scar. To send a woman back to daily life without mark or blemish, cured of a serious disability and danger, is an achievement of high artistry.

LAMINECTOMY FOR GUNSHOT WOUND.

WITH A RECORD OF THREE SUCCESSFUL CASES.

BY

D. M. HUGHES, M.B.LOND., F.R.C.S.ENG.,

MAJOR R.A.M.C.,

OFFICER IN CHARGE OF SURGICAL DIVISION, EDMONTON.

SURGEONS who have had a large experience of the spinal injuries of industrial practice cannot help being impressed by the high proportion of severe and inoperable cases found in comparison with the condition of things in war surgery. The reason for this difference is not far to seek. The coal mines furnish a large proportion of these cases, and the causal agent is so massive (a fall of roof in the pit, for example) that the lesion is necessarily widespread whether caused by direct or indirect violence. In gunshot wounds, on the other hand, a larger proportion of incomplete injuries is seen, and these are due to small missiles which, though they hit the spine, do not often make a direct hit upon the theca. When the theca is directly hit the lesion is complete in all senses of the term, and it is scarcely conceivable that even a part of the theca could be hit without causing such profound changes in the remainder of the segment as to cause, or at any rate initiate, a "complete" lesion.

Complete and Incomplete Lesions.

Complete gunshot lesions of the spine are due to direct hit of the theca, either by the missile itself or by the driving in of a part of the spine. Such cases show a complete interruption in the tracts of the cord—evinced by flaccid paralysis and loss of reflexes and sphincter control. If the theca be exposed by operation gross damage will usually be found, but occasionally the cord will appear uninjured (as has happened in my experience) and yet be completely and irrecoverably damaged.

In incomplete injuries, on the other hand, the missile hits the spinal column, but the theca is not hit either by the missile or by displaced bone, and the resulting paraplegia—

- (1) May be quite transitory and flaccid, but apparently complete;
- (2) May or may not have a transitory period of flaccidity and completeness, merging more or less rapidly into a spastic condition of any degree;
- (3) May only appear after an interval.

The pathological conditions underlying these three possibilities are pressure or irritation caused by effusion (intraspinal, subdural, or intramedullary), by granulation tissue in relation to a sinus or a retained missile, or by callus; with or without a preliminary condition of concussion. Incomplete lesions include a large proportion of conditions that hold out good hope of recovery, either spontaneously when the paraplegia is due to concussion, or in some cases to effusion, or after operation when a definite lesion is present. The indications for operation are so evident in cases of paraplegia arising after an interval that they require no discussion. When, however, a spastic paraplegia is present from the beginning the question whether or not to operate may be very difficult.

The indications for operation given by Sir George Makins from experiences in the South African campaign are so helpful and explicit that I will venture to quote them:

1. Excessive pain in the area above the paralysed segment; operation is here of doubtful practical use except in so far as it relieves the immediate suffering of the patient.
2. An incomplete or recovering lesion, when such is accompanied by evidence furnished by the position of wounds, pain and signs of irritation, of pressure from without, or possibly palpable displacement of parts of the vertebrae, that the spinal cord be encroached upon by fragments of bone.
3. Retention of the bullet accompanied by signs similar to those detailed under 2. . . .

Operation, if decided upon in either of the two latter circumstances, may be performed at any date up to six weeks, but if pressure be the actual source of trouble it is obvious that the more promptly operation is undertaken the better.

The purpose of this paper is to examine the outstanding features of traumatic paraplegia in the light of these indications and with reference to the possibility of treating underlying causes; to endeavour to show that the causes are very often extra-theal and therefore amenable to a comparatively safe operation; to indicate one or two practical points respecting the operation that have impressed themselves upon me; and to give a short account of three illustrative cases.

Prognosis.

The gravest sign is, of course, flaccid paralysis, which indicates a complete physiological interruption in conduction. It entails complete sphincter, motor, and sensory paralysis below the lesions, and is necessarily bilateral. It may, however, be quite transitory, as I have good cause to remember, having given a bad prognosis in an industrial accident of this kind, in which a month afterwards the patient was walking about. Persistent flaccid paralysis, it need scarcely be mentioned, places the case beyond scope of operation, except perhaps for the relief of girdle pain. Spastic paralysis, however, merits further inquiry, and I believe that involvement of the sphincters is of great prognostic importance.

Except in lesions of the lower cauda equina, where, in fact, involvement of the third and fourth sacral nerves frequently appears to be the salient feature, sphincter paralysis rarely appears without a high degree of motor involvement. I have met only one case, a mid-dorsal wound, and even in that, though the gait was not noticeably affected, the reflexes were very active and sensation diminished in both legs. The bladder trouble, which was of the nature of precipitancy rather than dribbling, had existed from the time of wounding; and in the absence of gross motor symptoms it is reasonable to suggest that the trouble might be due to intramedullary injury, perhaps a minute haemorrhage picking out the bladder-controlling fibres and exerting slight but not destructive pressure upon adjacent tracts. This reasoning is based upon the probability of the bladder fibres lying deeper and therefore less exposed to pressure from without than the tracts to the limbs, as the signs of a slowly increasing paraplegia would suggest. The slow progress of caries paraplegia gives good opportunity for prolonged observation. A definite order of involvement of nerve tracts is seen; motion is first affected, and very soon sensation, but a considerable degree of impaired sensation may exist with slight loss of motion. Sensation, however, is usually lost before the sphincters are affected. In recovery, sensation returns before motion, and sphincter activity precedes both. It is reasonable to conclude that a prolonged period of sphincter paralysis should affect prognosis adversely, especially when the compressing agent is displaced bone or callus, as may occur in gunshot wound. In caries paraplegia spontaneous recovery occurs in the remarkable proportion of 83 to 95 per cent. of cases (Tubby). It is to be noted, however, that many orthopaedists regard involvement of the sphincters as gravely affecting the prognosis, and this even in a condition in which the compressing or irritative agent is nearly always granulation tissue or pus, and not bone. In traumatic paraplegia, on the other hand, though in one of the cases described below (Case II) the causal agent seemed to be granulation tissue in contact with the theca, the offending body is usually something far less kind. Hence the smaller likelihood of recovery without operation, and, in fact, the probability, in the absence of operation, that complete sclerosis of the cord at the point of pressure will follow. It would be difficult to deny that sphincter paralysis is at least as grave a symptom in traumatic paraplegia as it is in caries. When it occurs from the first and does not rapidly improve, it indicates a lesion not amenable to operation; when late, it may indicate that the time for operation has passed, and this as much in relation to the fitness of the patient to undergo a severe operation as to the recovery of the cord itself.

Spontaneous Recovery.

Spontaneous recovery in concussion, when the whole thickness of the cord has been temporarily put out of

action by shock, has already been referred to, but a large number of cases of definite spastic paraplegia also improve or recover with rest. These phenomena are evidently the expression of vascular changes, varying from temporary anaemia of the cord to actual extravasation of blood in relation to the theca. It is highly probable that the spinal cord reacts to injury to its bony casing in much the same way as the brain. Cushing has shown that concussion of the brain is after all nothing more than a stage of compression and dependent upon the immediate vascular changes caused by the injury, the later stages of pressure causing anaemia and the earlier, with its clinical picture of irritation, congestion. The cord, however, is less closely applied to its dura than is the brain, and this would favour rapid "recoil" of the circulation following the anaemia primarily produced and encourage the production of minute intramedullary haemorrhages. The degree of recovery is closely related to the extent of these minute extravasations. They may be entirely absent (concussion with recovery), may be so small as only to cause a train of neurasthenic symptoms, or may cause an amount of intramedullary destruction and pressure varying from a slight nuclear or tract involvement to a complete transverse lesion.

It is hardly necessary to say that intramedullary haemorrhage is not of operative interest. Subdural haemorrhage from shock applied to the spine is a most unlikely event. If it occurred it would be small in amount, and there is ample space between the cord and the dura to allow it to develop without causing urgent pressure symptoms, and spontaneous absorption would probably follow. If the subdural haemorrhage followed a direct hit of the theca its presence would be masked by other severer signs. Intraspinal haemorrhage, however, is probably of great importance, as it is almost necessarily present in injuries to the bony tube, and, with or without the reparative effusion which accompanies the healing of fractured bones, accounts for the pressure in those cases of spastic paraplegia that recover without operation.

Distribution of the Paralysis.

With the possible exception of Case III, I have not met a unilateral lesion. One lower limb will frequently be affected more than the other, but a purely one-sided lesion in trauma must be very uncommon and the Brown-Séquard syndrome consequently must rarely be seen. Case III seemed to have shown this phenomenon in France, but by the time he reached this hospital the paralysis and anaesthesia were certainly most evident in the same limb, and the patient himself was emphatic that this had been the condition of things throughout. In the light of experimental section of the cord by Mott, Horsley, and others, however, this is what might have been expected.

A Retained Missile.

I have observed five cases in which the missile lay in the spinal canal and all were complete lesions. The temptation to remove the offending missile in such a position is great, and in three cases this was done. In one the exposure of the laminae disclosed a circular aperture through which peeped a shrapnel bullet, and the theca showed no damage. No improvement followed even in this case, and it is fair to conclude that the presence of a missile within the spinal canal is of very grave significance. Missiles in relation to other parts of the spine are fairly common, and if the theca has not been directly hit by them in their path, the paraplegia, if present, is of extrathecal origin and therefore amenable to treatment. This goes to prove that the etiological classification of gunshot wounds of the spine into complete and incomplete cases has a prognostic basis also.

The Question of Operation.

My own operative experience of laminectomy is limited to seven cases. Four were instances of flaccid paralysis with sphincter involvement and bedsores, and operation was undertaken for some specific reason—agonizing girdle pain, or the presence of a missile within the spinal canal, the removal of which, it was hoped, might improve matters. No improvement resulted; in two cases gross damage to the spinal cord was seen, and one patient, in whom the removal of the missile was followed by escape of turbid cerebro-spinal fluid, died. In the three remaining

cases, described below, operation was undertaken for spastic paraplegia of different degrees. In none was there involvement of the sphincters, and recovery of health and function was complete in each case.

To attempt to generalize from such limited experience would be of no value, but it is permissible to summarize the points that appeal to the operator. In the first place, it may reasonably be stated that the difficulties of the operation, though great, are not so formidable as is taught. The wound becomes very deep as the operation proceeds, and cozing is always troublesome. A free muscular separation, though it may weaken extension of the spine, benefits the patient by shortening the operation, and can be met by prolonged recumbency afterwards. Refraction cannot be efficiently effected by one assistant. The use of very hot lotion to stop oozing serves well to indicate those bleeding points which require ligature, and the operator should obtain as complete haemostasis as possible before the laminae are divided, for the intraspinal veins will give enough trouble without the added annoyance of blood trickling in from above. After the removal of the laminae, lotion hot enough to be really haemostatic might be harmful, and gentle patient swabbing until the fatty sheath can be opened and pressed aside is quite effective. When the dura spinalis is exposed firm pressure can be applied in a lateral direction and a complete examination made. Opening the theca admits such a great additional risk that the indications must be very definite to justify it, but my experience tends to show that in recoverable injuries the cause lies outside the dura.

It can be asserted that the special dangers of sepsis are small, provided it is not necessary to open the theca. A prolonged operation is always likely to admit a degree of sepsis even when performed under the best conditions. Hence, when a coarse decompression has been performed and the theca exposed, the surgeon may well ask himself what condition due to gunshot wound would indicate opening it with a prospect of success that would justify the risk. In each of the cases described below a degree of sepsis was present. Case I was postponed on account of the septic condition of the emergent bullet wound until it was thought unwise to put off the decompression any longer. The laminectomy wound as a matter of fact healed primarily. In Case II pus was encountered in the callus in the spinal canal and the wound was drained for a few days. In Case III operation was undertaken in the presence of a freely discharging sinus leading to the body of a vertebra; this sinus was probably the cause of the delay in recovery, acting possibly by inducing a mild localized myelitis or perhaps a local oedema of the cord. It is common knowledge that a paralysed peripheral nerve adjacent to a bone sinus, and thought previously to have been severed, will often recover spontaneously when the sinus has been efficiently dealt with.

The risks, then, of the operation in reasonably capable hands and with a practised anaesthetist are sufficiently small to warrant the statement that when there is only a chance of benefiting the patient operation should be performed. This is not to say that it should be urged upon him. In fact the patient himself, realizing he has no hope apart from operation, and that even that is slender, will sometimes desire operation when the surgeon realizes its hopelessness. Whether to buoy up the hopes of a patient doomed to permanent paralysis, or to inflict the additional misery of despair by strict truthfulness, is an ethical problem not likely ever to be settled.

CASE I.

Sergt. C., aged 31, was wounded on March 2nd, 1916, by a bullet which passed through the laminae of the seventh cervical and first dorsal vertebrae, fracturing both. Entry wound at root of the neck on the left side, healed. Emergent wound over the right acromion was a septic crater with bare bone at the bottom. On admission, March 10th, sensation was absent in both feet, dull in legs and thighs, and absent about the lower part of the thorax and up to the nipples. Movements of the lower limbs present everywhere, weakly executed, and readily fatigued. Reflexes very active and passing into clonus. No sphincter trouble. Further history is one of increasing paraplegia until voluntary movement ceased entirely and sensation was practically gone from nipples downwards. About March 28th involuntary clonic movements started in the legs, coming on in paroxysms, which awoke him at night. A necrotic patch appeared on the left heel. Fear of sepsis from the shoulder wound preventing earlier operation, laminectomy was not performed until April 22nd. The shoulder wound was covered by

a collodion dressing and the last cervical and first dorsal laminae removed. This was done piecemeal, as the laminae were represented by an indefinite mass of old and new bone, and it was very difficult to determine when the spinal canal was reached. This was, however, eventually well opened up, the fatty sheath separated, and the theca well exposed and lifted gently to free it. Pulsation good. Wound closed without drainage. Three days afterwards the patient volunteered that he could "feel his feet." Lower limbs immobile, very spastic, and involuntary movements as troublesome as ever. Within ten days the patient could, however, control the "spinal convulsions," and considerable muscular power was evident. By the end of June he could walk without support, and on August 25th was invalided, walking quite normally. Reflexes active, no clonus, anaesthesia about upper part of thorax.

CASE II.

Pte. G., aged 18, was wounded on March 20th, 1916, by a fragment of shell, which entered on the left side of the spine in the interscapular region; on the right side of the same region a counter opening had been made. Missile not removed. Admitted March 25th; x rays showed a piece of metal between the angles of the fourth and fifth ribs (right side) and damage to the right side of the fifth dorsal vertebra and neck of the fifth rib. No chest symptoms. Both wounds healed without removal of the missile and patient was sent to an auxiliary hospital on May 3rd. On May 28th the patient, who had been walking about quite actively for some weeks, was suddenly seized with weakness of both legs, especially the left, which gave way under him, and he fell to the ground. He was at once returned to this hospital. On readmission there was paralysis of the whole left leg, except for some fruitless twitchings of the front of the thigh. Superficial and deep reflexes grossly exaggerated; no Babinski. Light leg definitely weak, but all movements could be executed. No sphincter trouble. Partial anaesthesia in both limbs, with tracts of complete anaesthesia on outer side of the left leg and thigh. Wounds soundly healed. Operation June 3rd; the fifth and sixth dorsal laminae removed. When the theca was well exposed a nodule of soft vascular bone was seen projecting against the right side of the dura. The projection was continuous with a mass on the right side about the pedicles of the vertebrae, was easily lifted out, and showed a central core of soft granulation tissue, continuous with septic granulation tissue in the new bone close by. Theca gently freed and observed to pulsate well. Wound drained. Convalescence interrupted by pneumonia on second day; patient had to be placed in a sitting position with shoulders strapped to the bed-rest for two days; after that nursed on each side alternately. Temperature normal in six days. Recovery of paralysis by the end of June was nearly complete. Invalided out, walking quite normally, in August.

CASE III.

Pte. M., aged 20, was wounded on September 20th, 1916, by a shrapnel ball which entered between the vertebral border of the left scapula and the spine, and was localized as lying "behind or in the body of the third dorsal vertebra." He had been operated upon in France for removal of the missile, but his condition forbade completion of the operation. Notes from France indicated that a left motor and right sensory paralysis had existed from the nipple lines downwards.

On admission to this hospital on November 3rd, 1916, there was a discharging sinus in the centre of a wide vertical scar about two inches from the middle line. Movements of the right limbs were not affected. The left was paralysed below the knee and its reflexes were very active. Sensation was impaired on the same side, especially in the foot, and in the right limb, though not acute, was better than in the left. Condition slowly improved until hip and thigh movements were quite strong, but not more than a flicker of movement was possible below the knee. The sinus discharged as freely as ever, hence it was decided to attempt to remove the missile. This was done on January 7th, 1917, and as any attempt to explore the sinus would be dangerous unless its exact relation to the theca were known, the latter was deliberately exposed by the removal of the greater part of the third and fourth dorsal laminae. A probe was then passed forwards by the side of the left edge of the theca into the body of the third dorsal vertebra. The theca being protected by a small spatula, the ball was easily removed, together with a quantity of septic granulation tissue. The laminectomy incision was closed entirely and lateral drainage with gauze carried out along the course of the original sinns. Suppuration was free for two or three weeks, then rapidly improved, as did the paralysis. At the end of March the patient was walking with the aid of a walking-stick, and by the end of May walked quite normally.

Summary.

In Case I the paralysis, slight at first, increased to complete immobility of the lower limbs. In Case II the paralysis also existed from the time of wounding, but recovered to a considerable degree before operation. In Case II the paralysis occurred quite suddenly about nine weeks after the injury in a patient who was well and active. In no case was the Brown-Séquard syndrome (paralysis and hyperaesthesia of one side and anaesthesia of the other) seen, although Cases II and III were mainly unilateral lesions as far as motor paralysis was concerned.

Case II showed a patchy anaesthesia most marked on the outer side of the paralysed thigh, but the other limb was dull to pinprick; the fact being that when sensation is involved on both sides differences of degree are hard to detect, and, unfortunately, no attempt was made to discriminate between painful, thermal, and tactile impressions.

In each case (a) the paralysis was incomplete in the sense that sphincter trouble was absent; (b) the injury was indirect, and due to damage to the spinal column and not to the cord itself, and (c) recovery was complete.

The immediate effects of the operation in restoring or improving the circulation in the cord were not determined in any case. Decompression in laminectomy is a gradual procedure, and probably pressure is relieved long before the theca is exposed. The dura was not opened in any one of the three cases.

[The writer gratefully acknowledges the help of his colleague, Lieutenant Wellesley Simon, R.A.M.C., both in the clinical observations and the treatment.]

FIVE INTESTINAL OPERATIONS ON THE SAME PATIENT.

By HAROLD HARTLEY, M.D. LOND., F.R.C.S. ENG.,
SURGEON TO THE STOKE-ON-TRENT WAR HOSPITAL.

THE following case is interesting, not only because the patient had to be submitted to five intestinal operations in four years, but on account of its course and the difficult clinical problems it presented. The patient was a man born in 1894.

I.

Appendectomy, for acute appendicitis, at the North Staffs Infirmary in July, 1913; no drainage. Afterwards he had frequent attacks of sharp colicky pain in the right iliac fossa, but was not confined to bed.

II.

Exploratory laparotomy, at Hull Naval Hospital, in December, 1915, for severe pain in the right iliac fossa, with vomiting. The abdomen was opened near the appendectomy scar and closed without drainage.

III.

Ileostomy, for acute intestinal obstruction. He was admitted to the Stoke-on-Trent War Hospital late at night on January 14th, 1916. No satisfactory history could be obtained. The abdomen was opened by a median subumbilical incision. The small intestine was greatly distended; the large intestine loaded with hard scybalous masses. In the right iliac fossa was a mass of large and small bowel, inextricably matted together by very numerous and tough adhesions. There was great abdominal distension and profuse stercoraceous vomiting. He appeared to be moribund. A piece of ileum, as near the caecum as possible, was brought into the wound, stitched there, and opened at once. The stomach was washed out. The artificial anus acted well, but the skin around it became very foul and sore, and the man begged for a further operation.

IV.
Intestinal anastomosis, with bilateral exclusion of intestine, leaving mucous fistula. On February 11th, 1916, the artificial anus was plugged, and the soiled skin excluded, as far as was possible, by a sheet of sterilized batiste fastened down with I.R. strapping. A large flap of skin (Fig. 1) was marked out on the left side above the umbilicus, and turned over to the right. The abdomen was then opened just to the left of the middle line. The intestine was doubly clamped in two places—the ileum as near the artificial anus as was feasible, and the transverse colon in its distal third. Later, anastomosis was made between the ileum and the transverse colon (Fig. 2). Then the ileum was divided distal to the anastomosis and the transverse colon proximal to the anastomosis. Both ends of

FIG. 1.

the ileum were closed, as was the distal end of the colon. The proximal end of the colon was ligatured where crushed, and the end brought to the surface at X (Fig. 1), being fastened in position by several sutures. The flap was replaced without drainage.

The fistula soon only discharged clear mucus, which was not very irritating, and rapidly began to contract and heal round the exposed bowel, which became much less vascular, and did not show such active peristalsis as formerly. The end of the transverse colon brought out at X (Fig. 1) unfortunately disappeared beneath the flap, and mucus with clear watery fluid escaped at its left lateral margin. He took food eagerly, and rapidly regained

FIG. 2.—The bilaterally excluded bowel is shaded, and is the portion removed at Operation V.

weight and strength. The only disabilities remaining were the moisture from the fistula, and the fact that the bowels were always opened at least three times daily.

On August 6th, 1916, he was suddenly seized at breakfast-time with severe colic; no vomiting; no rigidity; great tenderness over caecum; temperature and pulse only slightly raised; great increase of fluid—now very malodorous—in spirits, from the fistula, where the exposed mucosa had lost its peristalsis.

On August 9th he was better and peristalsis was again seen at the fistula. On August 12th the skin at X (Fig. 1) showed signs of acute inflammation and soon discharge occurred with rapid relief of symptoms.

V.

Colectomy (July 18th, 1917).—A sponge was packed into the fistula. The incision was made through the entire length of the right linea semilunaris (Fig. 1), in its lower part invading the incisions of the first two operations. The abdomen was difficult to enter because of great vascularity, adhesions, and scar tissue. The adhesions in the right iliac fossa (see Operation III) had almost entirely disappeared. Thorough exploration was made, adherent coils separated, and all bleeding points tied. One adherent coil required inversion by a purse-string suture at the area of separation. Colectomy was started by mobilizing the caecum and ascending colon—this was easy and the mesenteric vessels were tied off very tightly with strong silk near the bowel, or in places where fat was very abundant, in the groove left by crushing forceps. Clamps were placed on the bowel side of the ligatures. More trouble was met with at and beyond the hepatic flexure because the empty part of the transverse colon was much atrophied—smaller than the ileum—and was shrunken up under the ribs owing to shortening of its mesentery. The mucous fistula was excised, and it was strange to find that six feet of ileum required removal before the blind end near the anastomosis was reached. The removal of the excluded portion of transverse colon was troublesome because of the poor access, adhesions near the anastomosis, and atrophy and irriability of this gut. The blind end was embedded in scar-tissue at X (Fig. 1), and a fresh incision had to be made encircling this pocket. Some oozing took place here, and as it was known to be previously infected tissue a split tube was left at X for two days.

He did well, and writing on October 4th, 1917, said, "I feel better now than for the last two years." Up to the present (March, 1918) he remains quite well; weighs 10 st. 10 lb., and plays football.

The following points in the case appear worthy of remark:

1. The adhesions found on January 14th, 1916 (Operation III), could not be separated by fingers and gauze. Their origin is obscure, and their almost total disappearance noteworthy.

2. The constant tendency to diarrhoea since 1913 is, perhaps, partly due to his very healthy and unrestrained appetite.

3. When he was operated upon for obstruction his moribund condition and the absence of history made the case difficult.

4. An ileostomy is a hateful proceeding, but it is the only life-saving measure to be considered in such a case. The bowel should be opened at once and the stomach washed out. Primary anastomosis should not be attempted.

5. The technique of intestinal anastomosis and bilateral exclusion of intestine presents few difficulties nowadays, but in the presence of an artificial anus special care is required to avoid infection.

6. Owing to an error of technique an adequate safety-valve was not procured for the excluded portion of colon. For a time the outlet at the ileal end was sufficient, but the instructive and interesting happenings in August, 1916, have been described to illustrate the dangers of relying upon the ileo-caecal valve to become incompetent—as finally occurred. A safety valve at both ends of bilaterally excluded intestine should always be provided.

7. It was astonishing that no less than six feet of ileum had to be removed at Operation V, in spite of the deliberate choice, at Operation III, for the ileostomy of what was thought to be a coil quite close to the caecum.

NOTES ON SURGICAL WORK IN A GENERAL HOSPITAL.

WITH SPECIAL REFERENCE TO THE CARREL-DAKIN METHOD OF TREATMENT.

BY

MAJOR J. S. DUNNE, D.S.O., F.R.C.S.I., R.A.M.C.

The following is written from notes made by me during the period of seven and a half months when I acted as officer in command of a surgical division of a general hospital at a port of embarkation. The situation of the hospital made it necessary that a certain number of beds should be left in reserve for cases from ambulance trains and ambulance transports when from any cause cross-channel traffic was held up.

Cases admitted had been treated by various of the methods advocated.

1. *Flavine*.—A number admitted from casualty clearing stations had been treated by flavine and Z paste, and had been kept by the casualty clearing station for a period of from six to ten days. The results were exceptionally satisfactory. The wounds in nearly all were closed; in some the sutures had been removed, in others the sutures were removed in this hospital. Only two showed signs of inflammation; one of these was a case of very severe multiple wounds, which would account for the incomplete operation performed. Where the patient can be kept under observation and an early and complete operation performed, this seems an ideal method of treatment.

2. *Bipp* cases did not arrive in the same satisfactory condition; most of them were thoroughly septic. In my practice, with two exceptions, bipp was used only as a sequel to the Carrel-Dakin method when the wound surface had become flat or too small for the application of Carrel's tubes. In the latter part of the period it was replaced by chloramine 4 per cent. in vaseline.

3. *Salt pack* cases arrived bathed in foul-smelling discharge; gas gangrene cases arrived with this dressing. Salt dressings were continued for a short time by one surgeon. *Bacillus pyocyaneus* was a constant complication, and the haemorrhagic granulations were a constant drain on the patient's vitality.

4. *Carrel-Dakin Method*.—Cases so treated invariably arrived in good condition, and if the complete operation had been performed and the technique strictly carried out, it was often difficult to realize that the patient was suffering from a dangerous wound.

An officer arrived after a very long train journey, sitting up on his stretcher, looking quite fit. Ten days previously he had been hit in the right lumbar region by a piece of shell casing 2 in. x 1 in.; there had been a jagged wound and rupture of the colon. Operation within twelve hours; the foreign body and fragments of clothing were removed, the lacerated muscles and fascia excised, and the rent in the colon closed. Carrel-Dakin dressings. On admission, the temperature was normal; there was one Carrel tube in the superficial wound, the remainder was closed and healed.

The Carrel-Dakin method gave the greatest satisfaction to me and was carried out thoroughly with the following technique:

Technique.

X-ray photographs accompanied the patient to the theatre. Ether soap, followed by methylated spirit and 2 per cent. iodine, were used to disinfect the skin. Free incisions were made exposing all injured structures and opening up dead spaces; the foreign bodies present were removed, and fragments of clothing looked for; all dead tissues, fascia, muscle, and fragments of bone without periosteal attachment to the shaft were excised, and all bleeding and oozing were controlled. Carrel's tubes were then placed in every part of the wound so as to ensure flow of

antiseptic towards the surface. Gauze soaked in Dakin's solution was placed lightly on the tubes. The adjacent skin surface was spread with gauze soaked in sterilized vaseline; the dressing was completed by applying a large Carrel dressing held in place by wooden clothes-line pegs. When the general condition of the patient made speed imperative, and the local conditions made complete operation dangerous, the injured part was rapidly explored, and incisions made to allow the Carrel tubes to reach the depth of the wound. This plan was so satisfactory that a second and complete operation could be performed without danger of septic absorption. The surgeon, assisted by a sister, nurse, and orderly—no more than he has for any other method—could carry out the after-dressings. The same preparations and precautions were used as for an aseptic operation as far as sterilization of dressings, instruments, and gloves is implied. The gloved hands were never permitted to touch the dressings. With each of the team doing his or her allotted part, ten large dressings could be accomplished in an hour. Sisters soon became expert, and taking the place of the surgeon, could carry out the dressings with success, the only difference being that the time occupied for each dressing was perhaps a little longer.

Bacteria counts were very efficiently carried out by a V.A.D. nurse trained in the work. The results were charted. Variations in the curve led to scrutiny of the technique, and delay in rapid improvement led one to suspect errors in technique, such as insufficient opening up of tracks, or, in comminuted fractures, necrosis of a doubtful fragment, or tubes badly placed.

Results.

Of 1,917 admissions, with 1,100 operations, there were 40 deaths. Many of these were admitted moribund from trains or hospital ships, and included 3 cases of tetanus, 2 of gas gangrene, 5 fractured femurs, and 2 unoperable neck wounds, 4 knee cases septicaemia on admission, 1 of secondary haemorrhage which developed gangrene after necessary ligation of the femoral artery, 2 buttock cases—one of these had longitudinal fracture of the neck of the femur with infection of the hip-joint—and many severe head injuries.

The success of the Carrel-Dakin method was obvious from the first. Secondary haemorrhage practically completely disappeared. There were three haemorrhages; two were reactionary, the third was a true secondary haemorrhage from an external saphenous vein, and was easily controlled without anaesthetic. The patients were cheerful and happy: dressings were not dreaded, and the nursing staff were pleased with the rapid convalescence of their charges.

Immobilization of Fractures.

The splints most in favour were Thomas's arm and leg, with or without superstructure; special splints were also obtained. At the end of the period under review, two officers who made a special study of constructing splints for individual cases were attached. I had not an opportunity of seeing splints for femurs, but their arm and lower leg splints were excellent. Compound fractures, both upper and lower arm, were amongst the up-patients very soon after admission; their apparatus, combined with the Carrel-Dakin technique, gave very good results. The large Carrel dressings are supplied to this hospital by the Irish War Hospital Supply Dépôt, Merrion Square, Dublin.

Carrel's method of instilling a potent antiseptic is both a life and a limb saving technique. Cases which arrived with the treatment in progress, even though the tubes might have been displaced in transit and a further operation proved necessary, could be approached without anxiety. In some other cases I would have amputated without hesitation as the only means of saving life but for this method.

Secondary haemorrhages need never occur if the technique is faithfully carried out. The method goes as nearly to giving complete physiological rest as is possible. Dressings need only be done every forty-eight hours, except in very septic cases, and there is none of that terrible nerve racking which other dressings entail. Patients watch the progressive improvement of their wounds with the greatest interest. In the Carrel-Dakin technique we have physiological rest reinforced by the scientific destruction of the local poison.

General Surgery.

During the period there were 481 major operations of a general surgical nature.

Appendicitis.—Of these operations, 103 were for appendix conditions, with 98 per cent. recovery. The incision recommended by Battle was used in 95 per cent. I modified it slightly by carrying the incision lower than recommended; by this I left the semilunar fold intact. Jackson's parieto-colic membrane

was found in two cases, Lane's bands in three. Two deaths occurred. The first patient was almost moribund from general peritonitis at the time of operation. The second, a Portuguese soldier, with gangrenous appendix involving the caecum, died from obstruction due to volvulus caused by a mass of faeces the size of a large orange. A case of appendix abscess was treated by drop irrigation with Dakin's solution, six or eight drops to the minute. The abscess cavity closed with extraordinary rapidity, and cases of faecal fistula yielded in a surprisingly short time.

Enteric Ulcer.—Two cases. One died a month after operation from intercurrent acute general tuberculosis, the other was transferred to England convalescent.

Acute Renal Cases.—Perinephric abscess, two; operation, recovery. Hydro-pyonephrosis, one operation; died.

Acute Cholecystitis.—One case. Operation in two stages: (1) Drainage; (2) excision of gall bladder. A pure culture of paratyphoid bacillus was grown from the contents of the gall bladder, though there was no history of this disease. He was transferred to England convalescent.

Gastric Ulcer.—One case, a Spanish sailor. The ulcer was closed, and gastro-duodenostomy performed. He was transferred convalescent.

In the work of a large hospital the best results are obtained not by the work of the officer in charge alone, but require in addition the zealous and enthusiastic co-operation of all the staff. I wish to express my thanks in particular to Captain Bourne, F.R.C.S., and to the Sisters whose careful attention to detail largely contributed to the success obtained in the use of the Carrel-Dakin method.

[Owing to want of space we have omitted reports of a number of cases, the course of which illustrated the excellent results described by Major Dunne as generally obtained.]

INFECTED FRACTURES:

TWO CASES TREATED BY LANE'S PLATES AND CARREL DRESSING.

By JOHN MACINTYRE, F.R.C.S. EDIN.,

MÉDECIN CHEF, HÔPITAL TEMPORAIRE, ARC-EN-BARROIS, HAUTE MARNE;
EXTRA DISPENSARY SURGEON, GLASGOW ROYAL INFIRMARY.

In the last ten months I have had over 500 cases of infected gunshot wounds, many with profound bone lesions, under my care at this hospital, and nothing but Carrel's method has been used. The results have been invariably successful; healing has been rapid, and in only two very badly infected cases have I seen secondary haemorrhage, and that only in the early stages of treatment. The charge that cases break down after apparent healing and evacuation from hospital is one that can be brought against any method of treatment. If the preliminary *débridement* has not been thorough, the surgeon will find cases breaking down; but it is not the method that is here to blame—it is the surgeon. Besides, a superficial breach of the surface of a scar of a wound treated by the Carrel method frequently ensues when massage and thermal baths are used for the stiffened joints and muscles that accompany the wound. This, again, might occur with any method of wound healing. The breaking down in any case is usually only superficial and slight compared with the great gaping wounds so wonderfully built up again by the aid of the Dakin solution.

I need not describe the method here; that is best to be found in Carrel's own book or Child's translation.¹ But it is better learnt from practice than from books. See someone who has mastered its use at work and then work at it yourself. It is not difficult, but a certain facility and sense of perspective can only come from practice, and are not to be got from precept.

One thing is of prime importance—the preparation of the Dakin solution according to Carrel's instructions. Failure usually comes from use of a faultily made solution, or from use of a carefully prepared solution which has been kept over-long and has deteriorated. In fact, the surgeon himself should be familiar with the process by which the estimation of the percentage of hypochlorous acid in the solution is made, and check this percentage for himself. If he does this he will have a proper strength of solution; if not, he may have a proper strength or he may not, and he must take the consequences in risks of failure. Nothing much can go wrong if the surgeon will spend five minutes twice weekly at the titration of his Dakin's solution. We have found that the best chloride of lime and other chemicals necessary for Carrel treatment are

those made by Poulenc Frères, Paris; but, of course, good, fresh, damp-free English chloride of lime may serve equally well.

To many the above may seem small or obvious details, but if the observance of them leads any one sceptical of Carrel treatment to a revision of his opinions and to his making full use of this new method, I believe that many lives and limbs will be saved.

I append notes of two cases which, although not gunshot wounds, may be of interest as supporting the claims I make.

G. R., on May 13th, 1917, at Landrecount, sustained by a fall from a wagon a simple fracture—spiral—at the junction of the lower and middle thirds of both bones of the right leg. Reduction was said to have been made under x rays, and a gutter plaster had been applied. He was evacuated to another hospital and then sent to us on May 21st. The bones seemed to be in good position, but there was a shortening of 2 cm.

Pressure of work on more urgent cases prevented my making a fuller examination until June 11th, when the plaster was removed, and not the least sign of union was found. Under x rays a left-handed spiral fracture of the tibia at the site above indicated was made out. Under ether, on June 21st, the fracture was exposed and muscle found intervening between the fragments. This was dislodged, and the ends of the fractured bones nibbled and freshened. An attempt was then made, with difficulty, to overcome the overlapping. The fracture being five weeks old the muscles had retracted, and the apposition was not all that could be desired. A Lane's four-screw plate was applied and the wound close sutured. An Edinburgh box splint was used.

At the operation I was short-handed for assistants during extension, and had myself to attempt, at one stage, helping with one hand to get the proper degree of torsion. The sterile foot-covering slipped, and I suppose that at this moment my hand must have come into contact with some non-sterile portion of skin, and been imperfectly re-sterilized by washing thereafter. In any case, an infection of the wound occurred; and on June 27th two of the lower stitches showed signs of infection. On July 2nd definite infection of the whole line of suture was present. The incision was opened up afresh and a Carrel tube led down to the plate, vaselined gauze applied to the skin around, and gauze pads soaked in Dakin's solution applied. Absorbent wool, covered by a layer of non-absorbent, was laid over this, and injections of Dakin's solution given by tube every two hours—that is, the usual Carrel treatment was followed. The leg was placed on a Pringle's splint for leg fracture.

The plate was removed on August 27th, when union was good, and by September 10th the wound was well healed under Carrel dressing.

On September 29th the patient was walking. There was slight eversion of the foot and some stiffness at the ankle. Massage to the whole limbs and single daily movements of knee and ankle were given during this rather lengthened treatment. The patient was evacuated, walking fairly well, to Bourbonne-les-Bains, a centre for mechano-therapy, on November 28th. The shortening was 2 cm.

The points in this case that seem to me of interest are:

1. Fracture at a site where good union is extremely difficult to obtain.
2. Definite control of a fresh infection of a clean wound during operation (even in the presence of so large a foreign body as a Lane's plate with four screws) until the bony union of a fracture is complete.

In the absence of Carrel treatment, such a case, instead of closing in ten and a half weeks, would probably fail altogether, or take three or four times as long, and necessitate several cleansing operations.

H. R. was injured on April 21st, 1917, at Verdun by a kick from a horse. He presented a badly infected compound fracture of the right tibia and fibula at the junction of the middle and lower thirds. He had received an injection of antitetanus serum on April 21st and a second on April 30th. It was impossible to say what treatment he had had in the way of dressing, but the fracture had been reduced and a gutter splint of plaster-of-Paris applied.

He was admitted to our hospital on May 2nd in the evening, and operated on thirty-six hours later. X rays had shown a comminuted transverse fracture of tibia and fibula at the junction of the lower and middle thirds; the comminution being confined to an area of about 3 cm. square in the tibia. At operation some splinters of dead bone were removed. A copious sanious discharge was present. The alignment of the upper and lower fragments of the tibia was good. The wound of the soft parts was dissected out and opened up freely. The ends of infected bony parts were nibbled off and gutters cut in the anterior surface of both fragments to allow of penetration of Dakin's solution to the cancellous tissue. Carrel dressing with five tubes was applied; and the limb immobilized in an Edinburgh box splint.

The wound continued dirty, and soft tissues remained swollen for sixteen days. Injections of antitetanus serum were made,

and seemed to have a good effect on the wound. The temperature range was from 37.4° C. to 39.4° C. The wound began to granulate well after the sixteenth day. On June 5th it was noted that the shortening of the limb was 4 cm. On July 7th the wound was well epithelialized all over, except for an area of about 1 cm. square. Movement could be elicited at the site of fracture. On July 15th a Pringle splint for fractures of the leg was used, with extension by strapping and weight. A rotating pull against eversion and a vertical pull against drop-foot were also applied.

By August 7th the surface was quite epithelialized, and under ether a Lane's plate with four screws was fixed over the fracture on the antero-internal aspect of the tibia. The wound was left widely open, and Carrel tubes and dressings applied. On August 24th the wound was granulating well, and the plaque was covered in at the upper end. On October 5th the plate was removed and the bone found to be well consolidated. The patient was evacuated to Bourbonne-les-Bains for massage and mechano-therapy on November 28th.

The shortening in this case was 4 cm., due to the comminution between the two principal fragments.

The points of interest in this case are similar to the last:

1. Fracture at a site where non-union is notoriously frequent.
2. Extremely bad infection of all parts, soft and bony, loss of bony substance, and gross trauma of the muscles and skin.
3. Definite control of the infection even in the presence of a large foreign body—a four-screw Lane's plate.

Without Carrel treatment I think this case would have required amputation at seat of election.

GONORRHOEA COMPLICATED BY SYPHILIS.

BY

N. P. L. LUMB, TEMPORARY CAPTAIN R.A.M.C.

In the past it has been customary to look upon syphilis as a much more important disease than gonorrhoea, and considerably more attention has been paid to it than to the latter. This is evident from the fact that a patient presenting himself with signs of both syphilis and gonorrhoea is commonly given thorough antisyphilitic treatment without delay, whilst the sum total of the treatment advised for gonorrhoea is an irrigation twice a day with permanganate of potassium. This plan is unsatisfactory, and an experience of large numbers points to the fact that modern antisyphilitic treatment at times (1) stirs a latent gonorrhoea into activity; (2) leads to the development of complications; (3) renders the gonorrhoeal lesions very intractable.

These three points are illustrated by the ten cases quoted below, all of which were treated by injections of arsenobenzol compounds (either by the deep subcutaneous method or intravenously) and weekly injections of mercury:

CASE 1.—Primary syphilis. No urethral discharge; two-glass urine test on admission: clear, no filaments. Gonorrhoea twelve months before; no relapse since. After four arsenobenzol and three mercury injections acute prostatitis developed, followed by inflammation of the left Cowper's gland, the pus from which was found to contain gonococci. Later there was arthritis of the left shoulder.

CASE 2.—Primary syphilis. No urethral discharge; two-glass urine test on admission: clear, no filaments. History of gonorrhoea two months before. Acute left epididymitis developed after ten injections of arsenobenzol and five of mercury.

CASE 3.—Primary syphilis. No urethral discharge; two-glass urine test on admission: clear, no filaments. Past history of gonorrhoea not clear. After three mercury injections acute prostatitis developed, followed ten days later by acute epididymitis.

CASE 4.—Primary syphilis. No urethral discharge; two-glass urine test on admission: clear, no filaments. History of gonorrhoea six months before; no relapse since. After ten arsenobenzol and seven mercury injections acute epididymitis developed.

CASE 5.—Primary syphilis. No urethral discharge; two-glass urine test on admission: clear, no filaments. History of gonorrhoea four years ago; no relapse since. After five arsenobenzol and three mercury injections acute epididymitis developed.

CASE 6.—Early secondary syphilis. The primary lesion appeared three weeks after exposure to infection, and there was a doubtful history of a slight purulent discharge for two days, possibly of balanitic origin. No urethral discharge on admission, nor subsequently for three weeks; throughout this period the urine was under observation; it was clear and free from filaments. There had been no previous attack of gonorrhoea. Three days after the third weekly injection of mercury and arsenobenzol a profuse purulent discharge appeared and the urine became cloudy. Eventually, when the discharge had been reduced to a minimum, the urethroscope showed clearly that Litré's glands were responsible for the trouble. Very persistent inflammation of them kept up a discharge for three months.

It will be observed that in Cases 1 to 6 there was no evidence of active gonorrhoea when antisyphilitic treatment was commenced; but in four of them a definite past history of gonorrhoea, varying from two months to four years, without subsequent relapse.

CASE 7.—Primary syphilis. Gonorrhoea evident on admission. After three arsenobenzol and two mercury injections acute epididymitis and prostatitis developed.

CASE 8.—Secondary syphilis. Gonorrhoea evident on admission; two months since exposure to infection. After three arsenobenzol and one mercury injection acute epididymitis developed.

CASE 9.—Primary syphilis. Gonorrhoea evident on admission. After five arsenobenzol and two mercury injections acute epididymitis and prostatitis developed, and later a small hydrocele of the affected testicle.

CASE 10.—Primary syphilis. Gonorrhoea evident on admission. Eleven arsenobenzol and eight mercury injections were given. One month after the last mercury injection acute epididymitis developed.

In Cases 7 to 10 there was evidence of gonorrhoea when treatment was commenced.

An analysis of these ten cases shows the following frequency of occurrence of each complication: Epididymitis, 8 times; prostatitis, 4 times; cowperitis, littritis, arthritis, hydrocele, once each.

Of the four cases in which gonorrhoea was evident, epididymitis developed in every instance, and prostatitis in two of the cases. Taken by themselves, these four cases (7 to 10) are not noteworthy, though it is unusual for gonorrhoeal epididymitis to develop in the ninth to tenth week, as in Case 10; but in conjunction with Cases 1 to 6 considerable interest attaches to them.

It is impossible to state definitely what is the cause of the onset of these complications, but the evidence points to the mercury compound rather than to the arsenobenzol. In another place¹ I have described a series of cases of acute gonorrhoea treated by injections of mercury compounds, such as enesol and mercury succinamide. In some of these it was found that epididymitis and prostatitis developed, without any exciting cause, as late as the tenth to twelfth week. This corresponds with the facts observed in Cases 2, 4, and 10.

At the moment of writing there are no figures available to show what the effect on the Wassermann reaction would be of withholding mercury for the first three weeks and administering arsenobenzol alone. If this could be done without detriment there would be a reasonable chance of controlling the gonococcal invasion before the mercury could exert any effect.

The number of cases recorded is much too small to allow any generalization, but it seems advisable to review the situation and consider what is the best line of treatment in patients presenting themselves with syphilis and either active signs of gonorrhoea or a past history of gonorrhoea.

The proportion of cases in which untoward effects are noticed seems to be about 10 per cent., and, in consequence, I have adopted the following routine in every case of syphilis, varying according to whether there are active signs of gonorrhoea or a past history of it.

1. When there is a past history of gonorrhoea and no active signs.

(a) A six to eight hours specimen of urine is taken twenty-four hours after the first mercury injection and examined microscopically for gonococci after centrifuging. The presence or absence of threads is also recorded.

(b) The prostate and vesicles are examined during the first week of treatment. A smear of the expressed secretion is made and examined microscopically for gonococci.

If both (a) and (b) are negative a dose of gonococcal vaccine is given (50 million gonococci), and test (a) repeated twenty-four

hours later. If no gonococci are found, no treatment is necessary.

If gonococci are found, the urethra is examined carefully with the urethroscope to locate the infection, and suitable treatment commenced at once, varying with the nature of the lesion.

2. When there are active signs of gonorrhoea.

Irrigation into the bladder with 1 in 8,000 potassium permanganate is commenced at once, the strength being rapidly increased to 1 in 4,000 as soon as the patient can irrigate successfully. Vaccines are given from the start at regular intervals and the prostate examined about the tenth day. A straight bougie is passed at the end of the second week, and this reveals the presence of any inflamed glands of Litré.

The whole idea of the treatment is to prevent the gonococci from getting settled down in the tissues and so prolonging the attack. The intractability of some of these cases, especially when littritis is present, has been referred to elsewhere,² and it is constantly necessary to vary the strength of the irrigating solutions and the instrumental treatment according to the progress of the case. It has not been considered necessary to refer to the various mechanical ways in which syphilis may complicate the treatment of gonorrhoea, as, for example, when a meatal chancre is present or phimosis results from the presence of a syphilitic abrasion, since the correct method of dealing with them presents no difficulties.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE LIFE-HISTORY OF ASCARIS LUMBRICOIDES.

I HAVE followed with great interest the discussion between Lieut.-Colonel Clayton Lane and Major F. H. Stewart on the life-history of *Ascaris lumbricoides*, and am familiar with the editorial note in the *BRITISH MEDICAL JOURNAL*, July 1st, 1916, which is frequently referred to by both of them in their papers (vide *Indian Medical Gazette*, August and October, 1917). I did not write on Major Stewart's letter, published in the *BRITISH MEDICAL JOURNAL*, September 30th, 1916, at the time, as no very useful purpose would have been served thereby, not enough work having been done at that time to determine the point one way or the other. Lieut.-Colonel Clayton Lane has dealt with the subject so fully in the *Indian Medical Gazette* (loc. cit.) that there is no necessity to say much more. He came independently to a similar conclusion to myself, that the passage of the ascaris larvae into the lungs of rats and mice indicated a vasculo-pulmonary circuit, as is seen in ankylostomiasis. Major Stewart's recent paper, published in *Parasitology*, January, 1918, which deals with *A. suilla* and the passage of its larvae to the lung of the pig, is very suggestive, and to my mind, though he did not always find adult ascaris in the intestines of his pigs after feeding with the ripe eggs, seems practically to prove the vasculo-pulmonary circuit. It certainly diminishes the force of the alternative hypothesis, that the lower animals act as intermediate hosts for the parasite, to practically zero. If *A. suilla* does the circuit in the pig, then it stands to reason—and this Major Stewart, I think, admits—that *A. lumbricoides* will do the same in man. If so, then there is only the other step for it to pass up the trachea, like the ankylostome, and so into the intestine, where it can become sexually mature. It is unfortunate that some of Major Stewart's pigs should have been infected before his experiments were begun, as it renders it difficult to say whether he reinfected them or not. The interval between the arrival of the larvae in the intestine and their development into adults may differ, and it may even be fairly long. The experiment to prove this point finally should not present insurmountable difficulties, and it is to be hoped that in the interests of helminthology this may shortly be carried out, preferably by Major Stewart himself.

GEORGE C. LOW, M.D.,

Assistant Physician and Lecturer, London School of Tropical Medicine; Temporary Captain I.M.S.

TREATMENT OF ORAL SEPSIS.

In my opinion, the original focus of the severer types of oral sepsis is at the margin of the gums and teeth. Mastication forces food in between the teeth, and between the gums and teeth. This food sets up a certain amount of irritation, and forms a suitable nidus for various organisms. The first problem is how to prevent food lodging in these sites; this can be solved only by efficient cleansing with a brush, which must be fairly stiff, and used after each meal in conjunction with a powder. I have found the following excellent: Mag. carb. pond. 3 parts; sulph. sublim., sapo Castil., aa 1 part; ol. menth. pip. q.s.

If gingivitis or pyorrhoea has already commenced, the affected area should be firmly swabbed with a small tightly rolled pledget of wool held in a pincette and dipped in liq. cresol saponis or any of its substitutes, taking care to remove the excess before using. A tumbler of warm water and spittoon should be ready to use immediately after. The thymol mouth-wash should be prescribed.

This method, I venture to predict, will come as a revelation to all who have laboured for weeks and months with iodine, hydrogen peroxide, and other methods, as it is so rapid in its effects; only in very advanced cases have I found it necessary to apply the liq. cresol saponis twice, and rarely three times, at two-day intervals.

In severe cases of pyorrhoea there is a dirty greyish-brown sloughing appearance at the gum margins, often jumping to the adjacent buccal mucous membrane; all these sites should be firmly swabbed, although the surfaces bleed in the process.

A similar condition is sometimes seen on the surface of the tonsils, and should be treated in a similar way; a sponge on a holder may be necessary here, dipped in sterile water or any mild antiseptic, if the person is too young or unable from any other reason to gargle. In septic conditions of tonsils and the back of the throat the ordinary chlorine gargle or swab should be applied every three or four hours after the initial swab with liq. cresol saponis.

A very septic socket may develop after extraction of a tooth, causing days and sometimes weeks of pain; if a swab soaked in liq. cresol saponis is firmly pushed into the socket, the relief is almost instantaneous, and a second swabbing after twenty-four or forty-eight hours is rarely necessary.

The pain inflicted in swabbing gums is practically negligible, but may be rather severe in the case of sockets.

I am indebted to Mr. H. Walker Ramage, L.D.S., Edinburgh, for the hint to use cresol.

Bo'ness, Linlithgowshire.

N. C. FISCHER, M.B.

PHARYNGEAL HAEMORRHAGE DUE TO LEECHES.

THE two following rather unusual cases came under my care during a single week in one of the general hospitals. The first was admitted with the diagnosis "haemoptysis" and the other as "haematemesis."

CASE I.

Pte. J. C., aged 24, stated that upon arriving in camp at dusk in the neighbourhood of Beersheba, ten days before, he took a drink of water in his cup from a running stream. A few hours afterwards he commenced coughing and brought up some blood. This continued up to the time of admission to hospital. No sign of lung trouble could be found. The pharynx was congested and his voice was distinctly hoarse. The coughing and haemorrhage continued until, during the night of the fourth day after admission, he complained of a choking sensation and difficulty in breathing. His cough was very irritable and he expectorated a considerable amount of blood. He coughed something into his mouth which he did not expectorate, as he "feared it was a piece of his lung." On the following morning he found this had stuck to his upper gum, and upon removing it found it to be a leech about one and a half inches long, which he had presumably swallowed a fortnight previously. Since then all discomfort and haemorrhage have ceased.

The patient had been in Egypt eight months and had had no previous illness.

CASE II.

Pte. A. T., aged 31, was admitted to hospital on November 24th. He stated that he was taken ill suddenly seven days before with a tickling, irritating cough, with spitting of blood each time he coughed. He was then in the environs of Ludd in Palestine. He obtained his drinking water from one of the wells; this was drawn up in a bucket, and he always used his cup for drinking. No symptoms of haematemesis could be

found. He complained of a tickling cough and sore throat, with spitting of blood. The pharynx was congested and he had pain in swallowing.

During the night of the second day after admission he expectorated half a sputum cup of pure blood mixed with a little mucus. On the following morning the right side of his face was swollen; I found what looked like dark clotted blood in the cavity left by two extracted teeth in the lower jaw, but on further examination it proved to be a leech one and a half inches long attached to the upper jaw. All haemorrhage ceased upon removing the cause of his trouble.

The patient had been in Egypt twelve months, and had had no previous illness.

I have ventured to bring these two cases under notice as the occurrence of "haematemesis" and haemoptysis arising from the presence of the leech in human subjects is sufficiently rare. It is quite possible that similar cases may arise, as it is probable that numbers of troops have drunk of water containing leeches.

As will be seen from the following report by Captain A. E. Rayner, R.A.M.C., the leech of Palestine may be found as an endoparasite of man.

The leech is lanceolate in shape, and about 1½ in. broad and 4 in. long when at rest. It is flattened antero-posteriorly, so that its ventral surface is practically quite flat; the dorsal surface is convex. Its colour is dark olive green, with a lateral stripe of gutta-percha red at the extreme edges of the body where dorsal and ventral surfaces meet. It has two circular suckers—the smaller oral sucker at the anterior end, the larger acetabulum at the posterior end. The body is divided by transverse ringed grooves into ninety-five segments. On the dorsal surfaces of many segments the nephridial openings can be seen. There are ten small black dots on the dorsal surfaces of segments at the anterior end—that is, five pairs of eyes. Of these the first and second are on the first segment, third pair on second segment, fourth pair on third segment. The fourth segment is eyeless, so that the fifth pair is on the fifth segment. There are three jaws in the oral orifice of the anterior sucker.

The leech is very actively retractile and extensible. It anchors itself firmly by the posterior sucker whilst the head and body plunge and writhe in all directions. It probably belongs to the subclass Hirudininae *Limnatis nilotica*. According to Castellani, leeches frequently occur in Algeria and Palestine as endoparasites of man, gaining entrance to the mouth or nose as he drinks from a pool. It may produce continued haemorrhage, with severe anaemia. It may act as the host for trypanosomes and other parasites.

[I am indebted to Colonel D. O'Sullivan, A.M.S., for his kind permission to publish these cases.]

J. M. BRIGGS,
Captain R.A.M.C.

Reports of Societies.

VENEREAL CLINICS.

At a meeting of the London Association of Medical Women on February 5th, with Lady BARRETT in the chair, Dr. JESSIE CAMPBELL gave an account of the work at the clinic for venereal diseases at Guy's Hospital. The patients came from the hospital itself or from outside districts, often from great distances, or were sent by private practitioners. Remarkably few belonged to the class of professional prostitutes, many being wives of soldiers or working girls. Three beds and two cots were attached to the clinic, and these were used for acute cases, or cases complicated by pregnancy, nephritis, or heart disease, also for those coming from a distance, and for children. District nurses attended patients at their homes. As all outward signs, except skin stains, disappeared after two to three injections, the patients were apt to attend irregularly, which was prejudicial to their cure. The Wassermann test was positive in a large proportion of the cases; it was often negative in pregnancy and in recurrent chancre. Of 40 consecutive patients who had undergone a full course of treatment, 27 gave a negative and 13 a positive test; of the 27 negative cases 22 were early and acute, and 5 late cases; of the 13 positive cases 2 were early and 11 late. It was thus doubtful how much reliance could be placed on the Wassermann test. Dr. TINDAL-ROBERTSON described the work at the evening clinic of the South London Hospital for Women, where her experiences were identical with those at Guy's, especially as regarded irregularity of attendance and absence of prostitutes among the patients. The tests for gonorrhoea were unreliable, and it was important that a satisfactory method of growing gonococci should be found.

Dr. AGNES SAVILL, in a year's work in the skin department of this hospital, had seen 13 cases of syphilitic and 78 cases of non-syphilitic skin disease. Of the total attendances 95 were syphilitic and 230 non-syphilitic. All but two of the syphilitic patients were married women. A syphilitic rash must be distinguished from pityriasis rosea, roseola, and drug rashes, and in the papulo-tuberculide stage from psoriasis and eczema of the palms and soles. Gummata sometimes resembled an iodide rash and condylomata a bromide rash. She had obtained very good results in gonorrhoea by ionization with a thick zinc rod and 2 per cent. zinc sulphate solution. Dr. ELSIE CHUBB said that much attention was paid to prophylactic treatment in men, while women were left altogether out of account, and this one-sided treatment would not help to eradicate the disease. Lady BARRETT said it was important to treat antenatal leucorrhoea even when no gonococci were found. Abortion did not follow careful direct treatment of the cervix. The best results were obtained by swabbing the cervix and vagina with argyrol and immediately afterwards with a 50 per cent. solution of picric acid in glycerin. Patients having 1 ad gonorrhoea should not be admitted into general maternity wards, even if apparently cured, as the disease often lighted up unexpectedly. At the Royal Free Hospital clinic the patients were also chiefly wives of soldiers and working girls who were not prostitutes, so that the suggested treatment of the prostitute class would be ineffectual in stamping out venereal disease.

NERVE INJURIES.

At a meeting of the West London Medico-Chirurgical Society at the West London Hospital on March 1st, Dr. J. A. RICE-OSLEY being in the chair, Captain E. FARQUHAR BUZZARD read a paper on injuries to nerves, their diagnosis and treatment. He predicated a thorough knowledge of the anatomy and physiology of muscles and nerves as an essential equipment for investigation. The electric battery was not necessary, and its evidence was frequently fallacious. Apart from inspection, it was impossible to say whether nerve continuity had been destroyed, but distal pain some hours after injury showed that its immediate effect had not been destruction of continuity. He uttered a warning against too readily ascribing to hysteria the terrible sufferings of many cases of nerve injury, more especially injuries of the median and internal popliteal nerves. Relief was a difficult matter; opiates should be avoided and recourse had to bromides, phenacetin, pyramidon, etc., given at night to ensure sleep. For intractable cases injections of alcohol into the nerve were recommended. Colonels DONALD ARMOUR and PERCY SARGENT, Mr. S. H. ROUQUETTE, Major H. SOUTTAR, Captain G. RIDDOCH, and Mr. H. TYRRELL GRAY took part in the discussion, which centred round the questions—when to operate, how to treat the nerve, and the suitability of various substances for its protection. All were agreed that end-to-end suture was to be aimed at, and grafts were unanimously condemned.

Reviews.

TAYLOR'S "PRACTICE OF MEDICINE."

THE first edition of Sir FREDERICK TAYLOR'S *Medicine*¹ appeared in 1890, four years after Fagge and Pye-Smith's *Principles and Practice* and two years before Osler's rival work. It has now firmly taken the place once occupied by Bristowe's treatise, so well known to a former generation, while Osler's, with its more personal and historical touches, has succeeded Fagge and Pye-Smith's exposition of medicine as exemplified by the practice of Guy's Hospital. Sir F. Taylor, as a teacher of long experience, has admirably met the student's needs by setting forth the present state of knowledge clearly, briefly, and without the statistics and references that may appeal to the more advanced reader who is working without the ever-present object of an examination before him. Similarly, from the ordinary student's point of view, it is an advantage to have included in one volume a condensed account

of skin and laryngeal diseases, on which the qualified practitioner would naturally consult special treatises, and, further, the details of treatment and the full discussion of alternative methods are hardly compatible with the requirements of space.

This volume is well balanced, exactly adapted to its purpose, and fully up to date. Since the last edition, published in 1914, the war has created new diseases, or at least brought certain affections, previously rare or unrecognized, into prominence, such as trench fever, spirochaetosis icterohaemorrhagica, and war nephritis, and these are succinctly described. Under the title "effects of strain and violent effort on the heart (soldier's heart)" an account is abstracted from Dr. T. Lewis's report to the Medical Research Committee on disordered action of the heart, for which the non-committal name of "effort syndrome" was suggested; it is at first sight rather disappointing that Sir F. Taylor does not endorse this, but perhaps the entry "effects of strain on the heart" in the last published (1906) edition of the *Nomenclature of Diseases* has influenced the President of the Royal College of Physicians in his decision. Many additions have, of course, been made, and the book has been thoroughly revised. The recent work on the treatment of acute poliomyelitis by immune serum from convalescent or recovered patients, and Allen's treatment of diabetes are duly mentioned; and the inclusion of trinitrotoluene poisoning, Dr. Cameron's views on lymphatism, and Dr. Willcox's recommendations for the dietary of beri-beri, show how carefully the changing face of medicine has been scanned. It is always possible to find something to criticize, and the method of estimation of the blood pressure, and the considerable space allotted to Arneith's count might be instanced in this case, if only to throw into greater prominence the general excellence of the work as a whole.

STUDIES IN THE HISTORY AND METHOD OF SCIENCE.

THE increasing specialization necessitated by the enormous advances of science is attended by the disadvantage that the groups of workers become somewhat isolated and acquire a narrowed horizon on which their aims are exclusively focussed. Further, in the pursuit of fresh knowledge the debt to the past is easily forgotten, and, as Sir W. OSLER points out in his succinct introduction to Dr. SINGER'S *Studies in the History and Method of Science*,² it is unfortunate that the progress of science makes useless the very works that made progress possible: the student is too apt to think that because useless now they have never been of value. The need for a comprehensive study of the methods of science has been met by the recent appearance of books and journals, and among these is the present collection of essays on the history of science, which, had not the war intervened, would probably have seen the light in a new *Journal of the History and Method of Science*. Most of these essays were in course of preparation before the war, and the author of the philosophical review of vitalism—the distinguished experimental embryologist, Dr. J. W. JENKINSON—was killed in action on June 4th, 1915, ten days after landing at Gallipoli.

Nearly half the volume is occupied by two scholarly and interesting contributions from Dr. Singer, to whom and to Sir William Osler the credit for the inspiration of this publication must be assigned. His analysis of St. Hildegard's scientific views and visions contains an extraordinary amount of research, presented in an attractive form and interspersed with shrewd observations, such as that though visions were the fashion and a common literary device in her times, there is internal evidence in the description of her visions that, like so many other distinguished people, she was subject to migraine with ocular manifestations. His valuable study in early renaissance anatomy contains the manuscript text of Hieronymo Maufredi's *Anatomy* in the Bodleian library at Oxford, transcribed and partly translated by Miss A. Mildred Westland. This text appears to be almost unknown. It was the first complete treatise on the subject originally written in Italian, and it represents with but little modification the tradition of Maufredi's predecessor at Bologna, Mondino, of whom a critical

¹ *The Practice of Medicine*. By Sir Frederick Taylor, Bt., M.D., President of the Royal College of Physicians. Eleventh edition. London: J. and A. Churchill. 1918. (Roy. 8vo, pp. xvi + 1091; 12 plates, 85 figures. 2s. net.)

² *Studies in the History and Method of Science*. Edited by Charles Singer. With an introduction by Sir W. Osler. Oxford: Clarendon Press. 1917. (Imp. 8vo, pp. xvi + 304; 41 plates (6 coloured), 32 figures. 21s. net.)

estimate is given. These two articles are copiously and finely illustrated by thirty-seven plates and twenty-three figures in the text, including two drawings by Leonardo da Vinci from the Windsor Castle collection. Dr. Raymond Crawford, the President of the Historical Section of the Royal Society of Medicine, writes on the blessing of cramp-rings—a chapter in the history of the treatment of epilepsy—and traces these rings from the time of King Edward the Confessor. Linacre, when President of the College of Physicians of London, lent his countenance to their use, which, it is suggested, may have originated in the Galenic belief that an epileptic seizure can be aborted by the application of a ligature to a limb above the starting point of the aura. In his essay on Dr. John Weyer and the witch mania, Dr. E. T. Withington details the horrors of persecution suffered by poor women who were tortured until they confessed imaginary crimes and then burnt; he points out that Weyer was the first serious opponent of the witch hunters, and that even one hundred years after the appearance of Weyer's book Sir T. Browne, the famous author of *Enquiries into Vulgar and Common Errors*, was responsible for the hanging of reputed witches. Mr. Reuben Levy throws doubt on the belief that Maimonides was the author of the unpublished *Tractatus de Causis et Indiciis Morborum*, and adduces evidence to show that it is improbable that he composed a treatise of this scope. In the concluding article, on scientific discovery and logical proof, Dr. F. C. S. Schiller, author of *Formal Logic*, discusses the limitations of the application of logic to the advance of science.

Dr. Singer is to be heartily congratulated upon the success of this beautifully printed and illustrated volume.

GAS GANGRENE.

The monograph on gas gangrene³ by ANDRÉ and JOSEPH CHALIER, containing as it does the full notes of the 103 cases upon which it is based, will be read with all the interest and attention due to the high repute of the authors. Its real merit is obscured, however, by the attempt they have made to give a precise meaning to the term "gas gangrene." Their method appears to be not to make the terminology fit the facts, but to select the clinical facts that can be brought within the legitimate meaning of the term. Thus they limit themselves to the consideration of a condition that is never originated in the head, neck, or trunk, and that is never associated with the presence of pus. If the reader will remember that the book is concerned only with those manifestations of "gas infection" which arise in the fleshy parts of the extremities, and are not characterized by suppuration, he will not be disappointed, however much he may wish the authors had adopted a wider standpoint, and employed their talent for observation and description for a more comprehensive purpose. A surgeon who has not seen gas gangrene will put the book down with a clear conception of a very important phase of infection by the *B. perfringens* and other anaërobic organisms, alone or associated with aerobic. The authors have apparently not met with the type of case, so frequent in British hospitals, at some times and places where the gangrenous process is limited to a single muscle or muscle group, and where the infection can be, so to speak, eradicated by ablation of the muscle or muscles up to their attachments. Nor do they mention, or, at any rate, lay due stress upon, the share of acidosis in producing the general toxic state—an omission reflected in their account of treatment. Three great "forms" are classified—the circumscribed, the diffuse, and the massive. Yet it seems necessary even for the authors to append a good sprinkling of "varieties"; and though they state that these may all be brought within the primary "forms," it requires no little strain. Withal, and notwithstanding what may appear vigorous criticism, the content of the monograph is valuable, quite valuable enough to withstand much more trenchant attack.

NOTES ON BOOKS.

WE have received from Lieut.-Colonel J. LLOYD JONES, I.M.S., a reprint of an article by him on "The young delinquent, his care and after-care," published in the *Social Service Quarterly*, Bombay, January, 1917. Colonel

³ *La Gangrène Gazeuse*. By André Chalié, Ancien Chef de Clinique Chirurgicale à la Faculté de Lyon, and Joseph Chalié, Ancien Chef de Clinique Médicale à la Faculté de Lyon. Paris: Félix Alcan. 1917. (Demy 8vo, pp. 388; 59 figures. Fr. 8.80.)

Lloyd Jones is Chairman of the Managing Committee of the David Sassoon Reformatory, Matunga, and in this article he reviews briefly what has been done in this direction. He points out that in Bombay provision has to be made for delinquents at an earlier age than at home—namely, from 8 or 9 onwards to 18. He relates the foundation, by the benevolence of the late Mr. David Sassoon, of the Matunga Reformatory and Industrial Institution (now mainly kept up by the Government), giving some details of the system pursued, and urging the importance of manual instruction under competent teachers, who know how to teach not merely how to manufacture, so that the pupils may become qualified for employment in suitable handicrafts, amongst which he mentions motor car and other engineering work. He deprecates street trading for juveniles. He rightly lays stress on the influence on character of a wise and sympathetic superintendent, able to maintain good discipline, and to direct into useful channels energies previously misdirected, consideration being taken of the mental and physical degeneracy by which so many juvenile delinquents are handicapped. After-care by voluntary associations is rightly insisted on as indispensable for success.

The volume on *Concrete Cottages*,⁴ by Mr. ALBERT LAKEMAN, is a highly practical work, illustrated by a number of photographs and drawings and by the report of the assessors who adjudicated in the competition for concrete cottages to be erected at a cost not exceeding £125, the amount to be exclusive of builder's profit, sanitary fittings, land drainage, etc., or the cost of drains and their connexion with sewers. The plans and drawings show considerable variety of treatment, the design which won the first place having a flat roof, a feature which may or may not prove to be well adapted to the climatic conditions of Great Britain. One of the sections of the book deals with methods and details of construction, four types of walls being enumerated—namely, those made of (1) hollow or solid blocks, (2) of concrete, plain or reinforced, filled in between vertical shuttering built up *in situ*, (3) concrete filled into horizontal moulds, each producing one side of the building and raised into position when sufficiently hardened, and (4) concrete poured in a more or less liquid state into wood or iron moulds erected complete to form the structure. The last plan does not seem to be of practical importance unless large numbers of cottages are being erected at one time. The book also contains designs for small garages and farm buildings, and a section giving general information for the builder as to plant and materials. The book is not one which could be criticized without going into details which would take us too far, but it can confidently be described as a thoroughly practical guide.

⁴ *Concrete Cottages: Small Garages and Farm Buildings*. Edited by Albert Lakeman, M.S.A., M.G.I. 1918. London: Concrete Publications, Ltd. (Roy. 8vo, pp. xii + 170; 169 figures. 5s. net.)

MEDICAL AND SURGICAL APPLIANCES.

An Improved Tourniquet.

DR. HEATON C. HOWARD (London, W.) has devised a modification of Petit's well-known tourniquet. It possesses the following features: (1) The pad is separated from the band, so that when the requisite amount of pressure is applied there is a space on either side of the pad by which complete constriction of the limb is avoided. (2) A counter pull, enabling the band to be applied easily and accurately. (3) A fastening providing a simple method of fixing the band, and of releasing the band and pad. It has been in use for over two years, and encouraging reports have been received. It is made by J. H. Montague, 69, New Bond Street, London.

ACCORDING to the *New York Medical Journal*, the laboratory of the U.S. Army Medical School at Washington shipped 8,843,047 c.c.m. of vaccine to Europe in the six months between April 1st and November 1st, 1917. Sufficient antityphoid vaccine has been sent to inoculate 1,051,604 men; of the double vaccine (paratyphoid A and B) to vaccinate 77,352 men. Since production of a triple vaccine (typhoid and both paratyphoids) on a large scale was begun, enough has been shipped to vaccinate 1,489,902 men. Each cubic centimetre of the triple vaccine contains 1,000,000,000 typhoid bacilli and 750,000,000 of each of the two paratyphoids. The United States army uses the Rawling strain of typhoid bacillus, isolated from a patient at Netley in 1900. The stock from which the typhoid vaccine is made is composed of lineal descendants of these germs propagated in artificial mediums during the last seventeen years. The paratyphoid vaccines are a combination of four strains, two British and two American.

COMPULSORY RATIONS.

REGULATIONS FOR INVALIDS.

GENERAL REGULATIONS AS TO PERMITS FOR INVALIDS.

In view of the difficult position in which doctors are likely to be placed in granting certificates to invalids for extra quantities of certain foods, it has been decided by the Ministry of Food, on the advice of the Committee of Reference of the Royal Colleges of Physicians and of Surgeons, and of the Central Medical War Committee, that for the time being these can only be allowed as follows:

1. *Sugar*.—Extra sugar shall only be allowed for persons with difficulty of swallowing solids due to organic disease—for example, cancer of the tongue, cancer of the oesophagus, gunshot wounds of the jaws.

2. *Meat, Butter, and Margarine*.—Extra meat and fat may be allowed for patients suffering from diabetes and from tuberculosis, also from coeliac disease and pancreatic insufficiency. No extra meat can be allowed for making beef-juice, beef-tea, or broth.

3. *Milk*.—Priority may be granted for milk as follows: In cases of acute illness—for example, pneumonia, typhoid fever, acute abdominal conditions—the doctor in attendance may give a certificate, on the receipt of which the milkman shall be empowered to supply the quantity of milk for one week. This certificate shall not extend for a longer period than one week, unless permission has been obtained from the Local Food Office. Extra milk may also be allowed for pregnant and suckling women; for invalids suffering from the following chronic diseases: nephritis, tuberculosis, certain gastric and intestinal conditions—for example, gastric and duodenal ulcers, gastrostaxis, enteritis, dysentery, and diarrhoea; recognized diseases and disorders associated with malnutrition, and for patients who are unable to take solid food.

Procedure.—Complete instructions with respect to the above are being issued to Local Food Offices, to which all applications must be sent, accompanied by a certificate signed by the doctor in charge of the patient. Each certificate must name the disease or condition from which the patient is suffering, and on account of which an extra ration is requested.

Duration of Validity of Permit.—No permit for extra rations shall be valid for more than one month.

Bread and Cream.

The Committee state further, with regard to bread and cream: (a) There is not sufficient evidence that the bread at present used is in any way injurious to health, nor that any disease requires bread made from "superior flour." (b) There is no disease for which cream should be allowed. Pending further instructions all inquiries respecting bread or cream should be referred to the Ministry of Food, Palace Chambers, London, S.W. 1.

DIETARIES FOR TUBERCULOUS PERSONS IN SANATORIUMS AND HOSPITALS.

The Local Government Board, in consultation with the Ministry of Food, has had under consideration the position of institutions for the treatment of tuberculosis in relation to the system of compulsory rationing now in force in London and the Home Counties, and to be extended, as is understood, to the rest of the country on March 25th. The following scales have been temporarily approved by the Food Controller. They are to apply only to patients actually suffering from tuberculosis. Officers of sanatoriums, unless themselves suffering from tuberculosis, must comply with the general scale of rations—namely, meat 1½ lb. (children under 10 to be allowed 10 oz.), butter and margarine 4 oz., sugar 8 oz. For the purposes of the rationing scheme "meat" is defined by the Ministry of Food as including butcher's meat and pork, bones, offal, suet and sausages, bacon and ham, cooked, tinned, preserved and prepared meats, venison and horse meat, and poultry, rabbits, game and hares. In certain instances a larger amount of these foods may be regarded as the equivalent of the rationed quantity of butcher's meat.

Dietaries for Tuberculous Persons in Sanatoriums and Hospitals.
Weekly Allowance of each Article "as Purchased."

	For Persons without much Constitutional Disturbance.		For Persons with Constitutional Disturbance.	
	Men. 14 pints	Women. 14 pints	Men. 21 pints	Women. 21 pints
Milk				
Meat (including suet) ...	3½ lb.	3 lb.	3½ lb.	3 lb.
Bacon	½ lb.	½ lb.	½ lb.	½ lb.
Fish	½ lb.	½ lb.	1 lb.	1 lb.
Cheese	½ lb.	½ lb.	4 oz.	4 oz.
Oatmeal	½ lb.	½ lb.	½ lb.	½ lb.
Pulses	½ lb.	½ lb.	—	—
Bread	4 lb.	3 lb.	3 lb.	3 lb.
Flour	½ lb.	½ lb.	½ lb.	½ lb.
Potatoes	5 lb.	4 lb.	2 lb.	2 lb.
Cereals	½ lb.	½ lb.	½ lb.	½ lb.
Sugar	½ lb.	½ lb.	½ lb.	½ lb.
Jam, syrup, etc. ...	½ lb.	½ lb.	½ lb.	½ lb.
Margarine and other fats	10 oz.	10 oz.	10 oz.	10 oz.

The scale for children under 10 will be three-fifths of the corresponding scale for the adult woman.

NOTE.—At any time it may be necessary to substitute equivalent amounts of other foodstuffs for not more than 1 lb. of meat or 7 pints of milk per week.

ROYAL MEDICAL BENEVOLENT FUND.

At the last meeting of the Committee, held on Tuesday, February 12th, nineteen cases were considered, and £198 voted to eighteen of the applicants. The following is a summary of some of the cases relieved:

M.B., C.M. Aberd., aged 67, who practised in India and Africa, and acted as ship's surgeon. Left hemiplegia recently. Only income, interest on £70 invested. His wife is now trying to obtain some employment. Has three daughters, all married, and unable to help. Voted £26 in twelve instalments, and referred to the Guild.

Widow, aged 51, of M.R.C.S. Eng. who practised at Stalham, Norfolk, and died in April, 1917, from tuberculosis. There were seven children, three of whom have died from tuberculosis. The eldest son, aged 22, is a lieutenant in the army. Only permanent income £15. Applicant has recently had to give up post as bookkeeper, so as to enable her to look after the other three children, who are delicate. Wants help towards the education of the youngest boy, aged 12. Voted £5, and referred to the Guild.

Widow, aged 40, of M.B. Irel. who practised at Hampstead and died in 1908. Applicant was left without means, and one daughter, now aged about 16, who is at a boarding school. Friends assisted her to establish a nursing home on the East Coast, but, owing to the war and air raids, she had to give it up in 1915. Has since had several posts, but, owing to indifferent health, has been unable to continue; is now looking for light employment. Voted £5, and referred to the Guild.

Orphans—boys, 17 and 15, girl, 12—of L.R.C.P. Glasg. who practised near Manchester and died in 1917. Mother also dead. Father died leaving debts and no provision for the children. Friends are endeavouring to collect money to provide them with a suitable home and education, and application has been made to the Fund for assistance. Voted £25, and referred to the Guild.

Widow, aged 69, of M.R.C.S. Eng. who practised in London, and died in 1893. Applicant is crippled and quite helpless. Income, rent of one house, £44. This is taken up by paying mortgage. Earns a little by painting. Relieved three times, £34. Voted £12 in twelve instalments.

Widow, aged 55, of M.R.C.S. Eng. who practised in Wiltshire and died in 1914. Applicant was left entirely without means, with one daughter, now aged 24, who is unable to help. Applicant is now working as a domestic help at a very small wage. Relieved five times, £40. Voted £12 in twelve instalments.

Subscriptions may be sent to the Acting Honorary Treasurer, Dr. Samuel West, at 11, Chandos Street, Cavendish Square, London, W. 1.

The Royal Medical Benevolent Fund Guild is now called upon, as a result of the war, to deal with many widows and children who, in happier times, would not have thought of asking for assistance. It is glad to receive secondhand clothing and household linen. The class of clothes most wanted is that suitable for boys and girls working in offices, for women, and for old men. The gifts should be sent to the secretary of the Guild, 43, Bolsover Street, W.

British Medical Journal.

SATURDAY, MARCH 9TH, 1918.

LUNACY LAW AND EARLY MENTAL DISORDERS.

THE need for amendment of the Lunacy Law, recently referred to in these columns, is a matter of such importance and has awaited solution so long that no apology is needed for reverting to it and examining it more fully.

The essential complaint is that mental disorders, so far as the great bulk of the people is concerned, have been regarded and treated from a different standpoint and on a different basis from physical disorders, with the result that the sufferers from mental disorders have failed to benefit from the modern advances in our views of disease and its prevention. Though in no department of medicine is the need greater for the earliest and most skilled treatment, yet hitherto these disorders have not been looked upon from a public health point of view, and in numberless cases the tendency of the existing law is to cause remedial treatment under the most advantageous conditions to be postponed until the disorder is so firmly established that the chances of cure are much lessened. This arises from the fact that the law governing these matters starts from the point of view of the lawyers, who are concerned to arrange how the public is to be protected from danger, how the individual is to be saved from false imprisonment, how his money is to be protected if he is wealthy, and how the money is to be found and spent for his maintenance if he is not. They do not look at the matter from the point of view of the public health, which asks how these sick persons are to be best treated so that they may be cured as early and in as many cases as possible. The lawyers' point of view is not unimportant, but it has been allowed to overweight the administration, has failed to a large extent from the public health point of view, and has inflicted hardships on the individual not foreseen by the Legislature at the time the law was made. Since then movements made in the interest of the public health have required some relaxations of the old rigid legal and financial views. Of this tendency instances are afforded in the Mental Deficiency Act, 1913, with its approved homes, in the compulsory powers for dealing with infectious diseases and tuberculosis, and in the financial support given to clinics for venereal diseases.

The medical profession, and the British Medical Association in particular, have for long years been alive to the defects and have taken steps to urge their remedy, but in vain. The war in this, as in other matters, has made it necessary to deal with the problem in a fresh, untrammelled way, and has provided an object lesson which should greatly aid us in reforming our civil procedure.

The ways in which the law acts as a deterrent to early treatment are in the main three. The first is the need for certification before any patient can be treated in a rate-aided institution for mental diseases; the second is the stigma of pauperism which the law inflicts on those so treated; the third is the want, for the most part, of arrangements for dealing with early cases of mental disorder in such a way as not to

brand the ailing person with insanity in his neighbours' eyes and all the disastrous consequences that flow from this, while yet maintaining a procedure which shall guard the safety of the individual and the public. In the army none of these difficulties stand in the way; large numbers of cases of recent mental disturbance have been dealt with in special hospitals for "functional nervous disorders" without certification in the vast majority of cases. Thus Major Eager, R.A.M.C., reports that at the Lord Derby War Hospital at Warrington, out of 3,800 cases, certification for transfer to an institution for the insane became necessary in 192 cases only, and in many of these only after many months' treatment without certification. At the Maudsley Hospital in London, which is now used by the War Office for similar purposes to those for which it was intended in civil life, the patients are treated without certification; whereas when the London County Council again takes over the hospital, unless the law is first changed, it will only be able to use it for certified patients, and the institution will technically be an asylum, instead of a hospital for voluntary patients and early cases as intended by the donor. The soldiers suffer from the stigma neither of insanity nor of pauperism, military discipline supplies the necessary powers of control, and there is no obstacle to the best treatment being supplied at the earliest stage of the illness.

What is urgently wanted is to bring these advantages within reach of the great mass of the civilian population when they are in danger of mental breakdown. Some reformers would advocate a complete recasting of the lunacy laws, and there are arguments in favour of such a course, but at the present time any such attempt would certainly involve great delay, and perhaps prove impracticable. The judicial system of certification which is the basis of the present law is common to the lunacy laws of practically every other country, and constitutes an important safeguard which Parliament is not likely to abandon, and there are large numbers of chronic cases for whom the provisions of the present law are desirable, and in the main unobjectionable. Moreover, there seems to be no great difficulty in drafting amendments to the present law which would achieve the desired results. Legislative proposals with similar objects were made in 1889, 1890, 1904, and 1905, and in 1914 the then Home Secretary (Mr. Herbert Samuel) promised to see what could be done in this direction by administrative action, without, however, any apparent result. The present time, when it is being proposed that the provision for persons of unsound mind now made under the Poor Law should be transferred to the county councils, together with all the Poor Law buildings, and when there is a prospect that all matters affecting public health may be brought under a Ministry of Health, would seem to be a favourable moment for bringing the question again before Parliament.

Generally speaking, what it is sought to bring about is that treatment on hospital lines shall be available for mental disorders, and that the procedure shall be of such a character that the patient on his own motion, or on the advice of his friends, shall be ready to take advantage of it at an early stage of his malady, as he would take advantage of an ordinary hospital, without coming under the Poor Law and without certification. The patient must not be brought into contact with the chronic insane, and every care must be taken that the hospital is not associated in the public mind with confirmed insanity.

While there is general unanimity as to the broad aims, when it comes to giving effect to them in detail

many debatable matters arise. For instance, it is asked what classes of mental disorder are to be considered suitable for such treatment. It is agreed that confirmed cases of long standing are unsuitable, but among the cases of recent origin some are of very gradual onset, and for a long time, or, indeed, throughout the whole period of their malady, it may be doubtful whether they could properly be certified as insane. Other cases may at the onset be acute and yet the prospect of recovery may be hopeful, so that they are not to be accounted confirmed cases. Is it desirable to distinguish cases on the ground of certifiability or on the grounds of recent origin and probable curability? For instance, are suicidal and violent cases all to be relegated to the asylum under certificates, or are they to be given the benefit of hospital treatment uncertified? Again, what powers of control and detention are to be given? This necessity may arise at any time in a recent or doubtful case, if the patient is not to be certified forthwith and sent to an asylum.

Another question is, What other cases are to be received in these hospitals? It is important not only that they should have a name, such as "Hospital for Nervous Disorders," that will not alarm or deter the patient, but also that the name should accord with the fact, and that patients suffering from disorders of the nervous system other than mental cases should be treated there; in the opinion of some its doors should be open wide to accept cases of organic and functional nervous diseases of all kinds.

We are now in a position to consider how the buildings for this purpose should be provided and maintained, where they should be situated, and the nature of the accommodation they should afford. Clearly the cost must fall on the public purse, presumably through the county councils. Possibly a Poor Law building may prove useful in some cases. It seems clear that the buildings, however provided, should be quite separate from the asylums; whether any of them should be wards or blocks of general hospitals is a matter for discussion, but there can be little doubt that they should where possible be associated with, even though locally distinct from, hospitals with teaching schools, so that both for students and practitioners the practical study of insanity and its treatment may be made feasible. Others would be required in every large centre of population. In all cases in-patient as well as out-patient accommodation would be necessary and facilities for research work on the spot and for the use of new methods of treatment. In the past differences have arisen as to whether such hospitals should or should not come under the supervision of the Board of Control, but opinion seems to point more and more to an affirmative answer, particularly with the prospect of the establishment of a Ministry of Health to which the Board of Control would presumably be subordinated. The question also arises whether notification of cases admitted to these hospitals is necessary or desirable, and if so, under what conditions, how soon, and by whom. It has also been suggested that patients declining to avail themselves of treatment should be notified by their doctor to the medical officer of health.

So far we have considered the provision necessary for those dependent upon rate-aided institutions. An amending Act should, however, include provisions granting similar facilities under proper safeguard to the well-to-do. For though these classes have had the advantage that they could be admitted as voluntary boarders to licensed houses or registered hospitals, there are many cases for which skilled treatment

is desirable who are able and willing to pay for it, but are unwilling to go as voluntary boarders where insane patients are received. This provision has not been extended to rate-aided institutions, and it is a hardship on those who could not afford to pay for themselves in a licensed house or registered hospital that it has not been open to them to enter the public asylums as voluntary boarders. It might be well to amend the law in this respect too, though it is doubtful whether the need would be so urgent if the proposals outlined above for special hospitals were carried out.

BARS TO THE VICTORIA CROSS.

In the summary of casualties and honours in the military medical services in 1917, which was given in the *JOURNAL* of February 9th, the belief was expressed that a clasp to the V.C. had been given only some four times. Dr. Wilfred L. Myles (Pontllanfraith) writes to suggest that this is incorrect, and that the only two clasps awarded since the institution of the decoration in 1856 have been those gained by Temporary Lieut.-Colonel A. Martin-Leake, R.A.M.C., and the late Temporary Captain N. G. Chavasse, R.A.M.C. Our correspondent bases his opinion on a passage in the introduction to the *History of the Victoria Cross*, by Philip A. Wilkins, published in 1904: "The Warrant authorizes a bar to be attached to the riband for any further act of conspicuous bravery on the part of the owner of the Cross, but no such bar has ever yet been issued, although statements to the contrary have frequently been made." Dr. Myles supposes that the mistake arose from the fact that three of the Crimean winners of the Cross—Admiral Sir W. N. Hewett, R.N., Captain G. F. Day, R.N., and Sergeant-Major John Berryman, 17th Lancers—were mentioned more than once for bravery during that campaign, whence the belief that a bar or clasp had been awarded them. As no official list of winners of the Victoria Cross since its institution is published, we have submitted the question to the War Office, whose reply confirms Dr. Myles in his view. The Assistant Military Secretary informs us that the only recipients of bars to the Cross have been the late Captain Noel Godfrey Chavasse, V.C., M.C., R.A.M.C., and Captain (now Temporary Lieut.-Colonel) Arthur Martin-Leake, V.C., R.A.M.C. The medical profession has every cause to feel proud of this unique distinction which is now placed beyond the region of doubt.

MALARIA CONTROL.

Two experiments on malarial control are related in Bulletin No. 88 of the United States Public Health Service. A town or community unit was taken, and antimosquito measures alone were applied to it, while in a rural unit each family or house received individual consideration, being protected by screening, or having quinine given in immunizing doses, supplemented by the sterilization treatment of carriers upon their detection by blood examination. The plan for these studies was prepared by the late Surgeon R. H. von Emdorf, formerly in charge of malarial investigations. Active field operations were begun in April, 1916, under the immediate supervision of Assistant Surgeon R. C. Derivaux, one of the writers of the present report. Surgeon von Emdorf died suddenly in September, 1916, and the completion of the studies was carried out by Drs. Derivaux, Taylor, and Haas. The results of the first experiment were very encouraging, and the amount of malaria in the township was greatly diminished and kept under good control. The results of the second experiment, as might be expected, were less convincing, especially that part dealing with the prophylactic use of quinine. Two doses of 5 grains each were directed to be taken in the morning and evening of two successive days each week, preferably on Saturday and Sunday,

making a total of 20 grains a week. For sterilization adults were given 10 grains daily, in two doses of 5 grains each in capsule, for thirty consecutive days. Such doses are much too small, and have recently been shown on numerous different occasions to be totally inadequate. The wonderful figures given are manifestly due to the infrequency of the blood examinations. If these had been carried out in greater detail such statements as the following could hardly have been made: "Of the 69 carriers to whom quinine was given for sterilization (in the amounts mentioned above), 62 remained under observation and were available for re-examination; of this latter number, 3 were found to have remained infected, a reduction or 'sterilization rate' of 95.17 per cent." This looks very marvellous, but an explanation is forthcoming when another statement, made on page 44 of the report, is taken into account—namely, "No re-examinations (of the carriers) were made upon completion of treatment, determination of the sterilization being provided for in repetition of the general parasite index." Even granting that this index was compiled from thick blood films, one examination is quite insufficient for estimating whether a patient is cured or not. It can hardly be doubted that if the 62 individuals had been followed more closely, and numerous blood examinations made, many would have been found still to be infected. Further, no risk of reinfections is taken into account. Though these results are open to criticism such experiments are not to be condemned. On the contrary, it is only by conducting well-thought-out schemes like those described that progress in the stamping out of malaria will come about. Destruction of mosquitoes and individual prophylaxis by living in mosquito-proof houses seem to be more useful than quinine administration, though the latter cannot be dispensed with as an adjunct.

THE FUTURE OF THE INTERNATIONAL RED CROSS.

It is to be feared that there is no longer any room to doubt that seven officers and forty-seven other ranks R.A.M.C. and eight women nurses lost their lives when the hospital ship *Glenart Castle* foundered. She was outward bound and had no wounded on board. The Admiralty states that it is "quite clear that she was sunk by an enemy submarine." She appears to be the seventh hospital ship torpedoed by enemy submarines. One of these was the Franco-Russian hospital ship *Portugal*, attacked on March 30th when near Of, in Eastern Anatolia. She sank in one minute with the loss of one hundred lives, including many women. This feat of war may have been accomplished by Austria, but the other six ships, all British, were torpedoed by German naval officers, who well knew what they were doing. The first hospital ship attacked seems to have been the *Asturias* when off Havre on February 1st, 1915. The torpedo missed then, but on the night of March 20th-21st, 1917, she was struck by one better aimed; 31 of the medical services and crew were killed, 39 were injured, and 12, including 2 women, were drowned. The hospital ship *Gloucester Castle* was torpedoed in mid-channel on the night of March 30th-31st, 1917, but all the wounded were saved. The *Donegal* was torpedoed on the evening of April 17th, 1917, and 29 wounded and 12 of the crew were drowned. The *Lanfranc* was torpedoed on the same evening, when 19 British lives were lost and 15 German wounded drowned; 152 wounded Germans were rescued by British patrol ships which the Germans failed to sink. The *Dover Castle* was torpedoed in the Mediterranean on May 26th, 1917, at 6 p.m., and again at 8.30 p.m.; six men were killed by the explosion, but all others on board were saved before the vessel sank. The *Rewa* was torpedoed, like the *Glenart Castle*, in the Bristol Channel, at midnight in the first week of January, 1918; all the wounded were saved but three of the crew were missing. The *Glenart Castle* had had previous experiences of the risks of this war. On

August 15th, 1914, when called the *Galician*, she was held up by a German converted merchant cruiser (*Kaiser Wilhelm der Grosse*) while homeward bound from Capetown. Next day the German cruiser signalled, "On account of your women and children I will not sink the ship." By March 1st, 1917, wretchedness of most unclean thinking had brought the German mind to a much lower ethical state. On that day the ship, which meanwhile had changed its name and become a hospital ship, was badly injured, presumably by a torpedo, in the Channel, but all the wounded she was then carrying from France were saved and the ship herself was got into harbour and repaired. Other British hospital ships sunk were the *Braemar Castle*, *Anglia*, and *Britannic*, but it was never conclusively proved that their loss was due to torpedoes and not to mines. But we may rest the accusation on the seven hospital ships deliberately torpedoed. The accusation lies against the German people, as a whole, but particularly against the German Emperor and Empress, the heads in that country of the organization of the Red Cross, whose symbol they had sworn to respect; and against the German intellectuals who justify the actions of their rulers. The manifesto of some eighty or ninety German professors, issued at the beginning of the war, justifying the atrocities then committed only in Belgium, will not have been forgotten, but it is not so generally known that by a recent comb-out of all the German universities the signatures of some nine hundred professors and the like have been obtained to a similar pronouncement. The officers and men of the R.A.M.C. and the nurses who have lost their lives in these ships gave them to their country and to the great cause for which the Allies are fighting as truly as the men killed at Mons, or Ypres, on the Somme, or at Vimy Ridge, or Messines. The heartfelt sympathy of the profession they have honoured will go out to their relatives. But there is the wide general question, What is to become of the Red Cross system? Germany, which was a party to the conventions, broke all her undertakings at the very beginning of the war, as was shown last week in the quotations from the white paper, and has gone on breaking them ever since, as is shown by the torpedoing of hospital ships to-day. Can she be admitted to any international organization of the Red Cross in the future? What guarantees for good behaviour could she give which any other nation will accept? And what is the position of the Austrian Red Cross? It held an International Red Cross Conference less than a year before the war, and though few Red Cross atrocities have been traced to the Austrian Empire, it is a thick and thin supporter of the German Empire.

THE ONWARD MARCH OF TUBERCULOSIS.

THE world-wide limitation of the supply of foodstuffs and the consequent restrictions of civilian dietary have begun to show varying results as regards public health. Reports from crowded communities go to prove that in many respects there is a diminution of disease of the gouty type, so often attributable to dietetic errors, but a decided increase in tuberculosis. The city of Vienna, always a hotbed of tubercle, has suffered a great extension of the disease and a marked rise in the death-rate, and similar results are only too likely to follow in other large cities with restricted food supply where the disease has already become firmly established. Mindful of this probability, the municipal authorities in Chicago¹ have taken vigorous steps to cope with the danger, and since August last the whole State of Illinois has been subject to drastic regulations, enforceable by fine or imprisonment, whereby all cases of open tuberculosis are kept under close observation, and debarred from transgressing the well-known precautionary measures for the protection of themselves and their immediate surroundings. School children

¹ City of Chicago Municipal Tuberculosis Sanitarium. *Monthly Bulletin*, January, 1918.

are rigorously protected from all known sources of infection, whether in the home or the classrooms, and the sale of milk, groceries or other provisions on premises occupied by a consumptive person is absolutely forbidden until such person is removed or rendered innocuous by arrest of the disease. The time would appear to be ripe for some such compulsory powers to be provided in this country. Not only are the existing measures insufficient for their purpose but they are not even enforced. It would appear that notification has served to detect only a small proportion of the existing cases of tuberculosis, and the majority of them must have been sources of danger for many months. Information and instruction have been widely disseminated, but hardly any attention has been paid to the teaching that they have conveyed. The country has accepted compulsion with respect to food supply in order to assist in checking the advance of the visible enemy on the Continent, and it is to be feared that only similar compulsion will serve to stop the onward march of the invisible, but not less deadly, enemy that threatens us at home.

LUMBAR PUNCTURE FOR OBSTINATE HEADACHE.

It has long been known that severe headache results in many cases from increased intracranial pressure. Instances have been recorded in which relief from such headaches has occurred after the spontaneous discharge of cerebro-spinal fluid from the nose or from the ears, or from both. Hence it is not unnatural to suppose that severe recurrent headache may in some cases be due to sudden increase of the pressure of the cerebro-spinal fluid, whatever the cause of this increase may be, and that lumbar puncture should relieve such headaches. Professor Mingazzini of Rome has recently¹ published an account of forty-seven patients treated on these lines. All these patients had more or less permanent or continuous headaches not relieved by the ordinary methods of medical treatment; six were men, forty-one women. Cases with tuberculosis, syphilis, granular kidney, chronic alcoholism or excessive tobacco smoking, epilepsy, and intracranial tumour, were excluded from this series of patients. In every case the cerebro-spinal fluid withdrawn was found to be normal on examination, free from globulin, and containing only a few lymphocytes. As a rule, the lumbar puncture made the headache worse for a few days, but a definite cure was obtained in twenty-four cases and a considerable improvement in fifteen more. No benefit resulted in the remaining eight. One patient, a woman of 60, who had had frequent headaches since her youth and daily for the preceding six months, was cured by a single lumbar puncture; another patient, a girl of 22, who had had headaches for two years, after typhoid fever, received no benefit from the puncture. It was noted that if the pressure of the cerebro-spinal fluid was normal or low, lumbar puncture failed to relieve the headache; it was successful where the pressure was found to be high. The results seemed independent of the quantity of fluid withdrawn; thus no improvement might follow the removal of 15, 20, or even 30 c.cm., while cure might follow the withdrawal of 10 or even 5 c.cm. Analysis of the histories of the patients seemed to show that the treatment acted best in cases in which the headaches had begun at the age of 10 or 20, and had later become permanent for no appreciable cause. The patients not improved by the puncture were those in whom the headache had been permanent from the outset, or had begun later in life and become permanent after lactation or the onset of some illness, or was associated with a neurosis, such as trigeminal neuralgia or epilepsy. Permanence of the headache for more than a year seemed to make a cure by lumbar puncture unlikely. The pathology of these headaches Professor Mingazzini leaves, as he found it,

obscure. They are thought to depend on increase in the quantity and pressure of the cerebro-spinal fluid, due to some upset in the balance between secretion and absorption. Some connexion between the choroid plexuses, the main secretors of the fluid, and glands with internal secretions, such as the ovaries or testes, has been thought to exist; this would explain, in part, the frequency of monthly headaches in women and the general tendency of headaches to grow less with advancing years.

EPIDEMIC JAUNDICE IN A DANISH ISLAND.

Dr. J. Kamp and Dr. T. B. Wernöe¹ state that in the Danish island of Bornholm a disease prevailed for many years the chief characteristics of which were jaundice, diarrhoea, and extreme prostration. In the period 1900-1915 there were between 200 and 250 cases among a population of only 5,000 to 6,000. In 1908 alone there were 70 cases, and there were 48 in 1912. In other years there might be only about a dozen cases. The village of Nexø was the centre of this disease, and even the sporadic cases observed at a distance from it could invariably be traced back to Nexø. Besides the jaundice, which usually lasted many weeks, there was tenderness over the gall bladder, and the area of liver dullness was increased. The watery, mucous stools were often blood-stained, and the associated colic was, as a rule, confined to the umbilical region. The diarrhoea was intractable and persisted for weeks and even months. The patient's general condition recalled the typhoid state, and complications were numerous, including haematuria, haemorrhage from nose and mouth, bronchopneumonia, myocarditis, and abscess of the liver and brain. The disease would break out again and again in the same house, attacking the same or different persons at irregular intervals. In such houses the domestic animals, notably calves and young pigs, suffered from recurrent attacks of severe enteritis. When, in 1914, steps were taken to isolate the patients in hospital, the number of cases soon diminished, and during the last three years none occurred. Examination of the blood, faeces, and urine was usually negative; only twice was the paratyphoid B bacillus found. It was also found twice in material obtained from sick calves and pigs. On these rather slender grounds the authors attribute the disease in both man and domestic animals to this microbe, which, they suggest, was imported to the district from California by an old workman who had contracted a dysentery-like disease there as a young man. He suffered subsequently from blood-stained diarrhoea every spring and autumn, and had recovered from a liver abscess. He did not seek medical aid until he was 60 years of age and moribund. The examination of the blood, faeces, and urine in this case was negative.

TUBERCULOSIS IN CHILDREN.

A COMMITTEE of the National Association for the Study and Prevention of Tuberculosis in America has published certain standards for the diagnosis of tuberculosis in children. The report has been critically examined by Dr. M. Fishberg of New York, and his remarks² contain points of interest, but many of them apply only to pulmonary disease, whereas the report of the committee deals with tuberculosis as a whole. He objects to the idea of standardization of diagnostic methods on the ground that many of the symptoms so standardized may be caused by other pathological conditions. Pulmonary tuberculosis in children between 5 and 10 years of age is as seldom met with in American clinics as in our own, but a very large proportion of children between those ages show a positive reaction to tests. The tuberculous lesion which is so fatal to infants under 3 is of bronchopneumonic type, and is only too common. Tracheo-bronchial adenopathy is frequently present in the first decade, and may give rise to

¹ *Il Policlinico, Sez. Medica, Rome, xxiv, July, 1917.*

² *New York Medical Journal, November 24th, 1917.*

symptoms, and even physical signs, which are liable to be misinterpreted. Dr. Fishberg considers that the classification of such cases as consumptive and their treatment by segregation from the ordinary round of life is greatly to be deprecated, since the vast majority do perfectly well without any treatment at all.

THE CASE-BOOK OF SHAKESPEARE'S SON-IN-LAW.

DR. R. W. LEFTWICH read an amusing paper before the Shakespeare Association on March 1st on the case-book of Doctor John Hall, Shakespeare's son-in-law, who practised in the early part of the seventeenth century at Stratford-on-Avon. The original MS. of the case-book—a small duodecimo volume—is in the British Museum. The 180 "cures" which it described were arranged in no sort of order; only 21 were dated, and Hall's syntax was so awkward and his Latin so much abbreviated as to make the descriptions in parts unintelligible. One of the cases, for example, was marked "Feb. 3," which looked like a date, but must have meant tertiary fever. Hall's own practice, for which, in Dr. Leftwich's opinion, he had been licensed by the Bishop of Worcester, extended as far from Stratford-on-Avon as Gloucester, Northampton, and Ludlow. Yet he was no very skilful physician, even judged by the standard of his time. He was weak in details of diagnosis, though of details of a less relevant order he was full; his female patients, for instance, were described as fair, pious, and chaste, and many of the cases ended with a pious reflection. His armamentarium was almost exclusively herbal. In mentioning metals and stones as therapeutic agents Shakespeare was in advance of his son-in-law. Hall had a liking also for the disgusting remedies of the Middle Ages. One of his prescriptions was white wine with ten crushed garden worms, but the patient so treated declared himself deeply grateful, and that Hall had been a father to him! He did not often dip into astrology, though he gave occasional directions as to the taking of medicine at the time of new and full moon. It was claimed for him that he was the first to use antiscorbutic remedies—various grasses and watercresses in beer. Dr. Leftwich concluded by observing that it was hard to forgive Hall for his silence respecting Shakespeare. With the opportunities of a Boswell, he left not a biography but a case-book.

THE President of the Local Government Board has appointed Mr. J. B. Lawford, F.R.C.S., consulting ophthalmic surgeon to St. Thomas's Hospital, to be an additional member of the Advisory Committee appointed to advise the Board on matters relating to the care and supervision of the blind.

LIEUTENANT-GENERAL SIR ALFRED KEOGH, G.C.B., on relinquishing the post of Director-General of the Army Medical Service, has been appointed by the King to be a Companion of the Order of the Companions of Honour for services in connexion with the war. The Order, which was instituted last year, consists of one class only. Sir Alfred Keogh is the twenty-first Companion and the first member of the medical profession to receive this honour.

AMONG the fifteen candidates who have been selected by the Council to be recommended for election into the Royal Society are three members of the medical profession: Dr. Charles Bolton, Physician to University College Hospital; Surgeon H. B. Guppy, R.N. (retired); and Dr. Thomas Lewis, cardiac pathologist and assistant physician to University College Hospital. Of the consulting physicians, physicians, and assistant physicians to University College Hospital four are already Fellows of the Royal Society. Six physicians on the staff of one hospital holding this distinction must constitute a record.

Medical Notes in Parliament.

The Medical Treatment of Conscientious Objectors.—In the House of Commons on February 28th, in Supply, a debate was initiated by Mr. Whitehouse, raising amongst other questions the treatment of conscientious objectors. Sir George Cave, in his reply, said that there had been more than 5,000 of these men in prison from time to time. The total number of deaths in prison was two, both due to sudden and severe attacks of pneumonia. In both inquests were held, and in both the jury found a verdict of death from natural causes, adding a rider in each case, wholly acquitting both the prison doctors and the prison authorities of any neglect or want of care. The total number of deaths among the men in the camps, of whom there must have been somewhere near 4,000 altogether, was 8, or 2.5 per 1,000 per annum, and he would be very much surprised to learn that that was not a very satisfactory figure even as regards men of this age. Dealing with a specific case mentioned by Mr. Whitehouse which had been transferred from Dartmoor to a camp and had died there of diabetes, it appeared that sugar was not found in the urine until a day before his death. The case appeared to have been an unusual instance of acute diabetes. A medical record was always sent with a man, and on leaving Dartmoor he was medically examined and a report made showing what kind of work he was fit for. Special inquiry into what was called the strike of conscientious objectors at Dartmoor was made by Major H. Terrell, M.P., who heard evidence and statements from the conscientious objectors as to the man who died of diabetes; the findings of the coroner's jury seemed to have been correct. The number of conscientious objectors who had become insane was 13; in every case there were pre-existing causes, and the insanity was due neither to the conviction nor to the treatment. Of the 13 men mentioned, 12 were at once removed to asylums; the other was handed over to the care of his wife. Arrangements had been made with the War Office by which, if a prison doctor gave a certificate showing that a man was unfit for military service, it was accepted as conclusive. Every such case was reported to him, and he had directed the release of 28 such men. During the debate, Major Terrell gave an independent account of his visit to Dartmoor. The complaints he had met with were that the doctor had not certified men for discharge early enough, and that in certain instances he acted harshly. One specific case made by the secretary of the men's committee was as to a man who was insane, and was put into a padded room; the men were asked to take charge of him, but refused; the patient was then sent home and discharged; it was understood that he was now in an asylum. Another complaint was that a masseur was not provided at Dartmoor for two men who had met with accidents. He said that every complaint was investigated, and if there was any justification the matter was rectified.

R.A.M.C. and the Air Force.—Colonel Gibbs has stated that the transfer or attachment of R.A.M.C. officers could not be carried out until the actual formation of the Air Force. All steps were being taken to complete the arrangements for the medical care of the new force.

Sterilized Tuberculous Meat.—Mr. Clynes stated that he was aware that in most Continental cities carcasses slightly affected with tuberculosis were sterilized and used for human food, and that a certain amount of such meat was being so treated in Scotland. The advisability of extending this method was under consideration.

Tuberculous Discharged Men.—In reply to Major Davies, Sir A. Griffith-Boscawen stated that the Ministry of Pensions had no power to pay the expenses of treatment of discharged disabled men suffering from tuberculosis so far as provision is otherwise made for them. Arrangements had, however, been made to defray the cost of treatment in advanced cases, and in early cases sent for prolonged treatment and training to farm colonies. The insurance authorities had also been assisted to provide additional grants-in-aid to secure preferential treatment generally for discharged men. With regard to a substantial proportion of the men it was incorrect to say that they were not suffering from the disease when they entered the army but had contracted it during the period of military service.

Maisons Tolérées in France.—In reply to Mr. Lees Smith, on March 5th, Mr. Macpherson said that, as far as his information went, the question of placing *maisons tolérées* in France out of bounds did not arise unless British troops had been misconducting themselves under circumstances which in the interest of discipline rendered it necessary to place such institutions out of bounds.

A LINNEAN SOCIETY has recently been established in Sweden, the object of which is to diffuse information as to Carl Linné or Linnaeus (1707-78). In fulfilment of this purpose the society will publish writings of the famous naturalist and his pupils; throw light on the personality of the man from modern points of view; draw up a catalogue of all known memorials of him and his work, and found a complete Linnean library. The president is Dr. Tycho Tullberg, a lineal descendant of Linné.

THE WAR.

SECOND REPORT OF THE COMMITTEE ON PYREXIA OF UNKNOWN ORIGIN AND TRENCH FEVER.

THE DIAGNOSIS OF P.U.O. FROM ENTERIC.

THIS question was, as stated in the first report (BRITISH MEDICAL JOURNAL, January 19th, 1918), one of the objects which the Committee set before itself. That report dealt with 170 consecutive cases in which that diagnosis was purposely not made. The next 200 cases form the material of the present report. The clinical examination has been in the charge of Captain Horsley Drummond; the pathological has been carried out by Captain W. H. Perkins, who was specially detailed for this purpose. Their report was, with a few emendations, adopted by the Committee, which has throughout been in constant touch with the work.

The clinical examination of these cases, in addition to a careful record of symptoms, signs, temperature and pulse, has included also observations on blood pressure, on the atropine escape, and in a few cases on the cytology of the blood.

On the pathological side cultures have been made from the blood in all cases admitted at a sufficiently early period of the disease, and while the patient remained in hospital specimens of stools and urine have been bacteriologically examined twice weekly. The agglutinin titre has been determined at least thrice in every case.

The diagnosis of enteric fever in former days rested upon the clinical symptoms, the recovery of the organism, and the formation of a specific agglutinin in the blood, which was shown by Widal's test. The introduction of prophylactic inoculation has rendered the diagnosis much more difficult.

Certainty can only be attained by the recovery of the organism. But since inoculation against typhoid, and especially since the triple inoculation now in use has been practised, experience has shown that in only about 40 per cent. of cases which (1) clinically appear to be enteric, or (2) give the agglutinin reactions of enteric, or (3) afford evidence of both kinds, can the organism be recovered from the blood or excreta, even though the former be examined early and the latter repeatedly. This clinical

experience has been confirmed by *post-mortem* evidence, for the characteristic lesions have been found, though the organism could not be recovered.

On the other hand, the mere presence of agglutinins is no longer of the same cogency, since they remain as a product of prophylactic inoculation. In the course of an enteric fever, however, there is an increase of the agglutinins and a consequent rise in titre, which reaches its maximum about the third week of the disease. This rise and a subsequent fall of titre to the normal level constitute the "agglutination curve," which has now been invested with great importance in the diagnosis of the enteric fevers.

In the present series of 200 cases the agglutination test as an aid in diagnosis has been utilized in all, the method adopted being that associated with the name of Professor Dreyer.

Specimens of blood from all patients have been examined at intervals of four days, and the agglutinins for typhoid, paratyphoid A and paratyphoid B quantitatively determined. The technique elaborated by Professor Dreyer has been followed in all particulars. Readings have been recorded after immersion of the agglutination tubes for two hours in the water bath at 55° C. and controlled by a further reading at the end of twenty-four hours. The titre of the serum at which standard agglutination occurs has been arrived at by means of Dreyer's interpolation table, and the results of the tests in the cases recorded in Table II are expressed in standard agglutinin units.

It may be stated at once that in none of the 17 cases there recorded has an organism been isolated from blood, faeces, or urine. From the pathological standpoint the diagnosis has been arrived at solely on the results of the agglutination test.

It must be remembered that the practical value of this test as a diagnostic measure has been much questioned. It has been asserted that febrile diseases other than enteric may influence the production of agglutinins for typhoid and the paratyphoid organisms; but in the present series of 200 cases over 90 per cent. fail to show that agglutinin response which is characteristic of enteric infections. The results of the clinical examination of these cases have been recorded in Table I.

The first 8 cases are those which to the clinician most closely suggested an enteric infection—those which, before the results of the agglutination test were available, he viewed with greatest suspicion. The remaining 9 cases

TABLE I.—Summary of Clinical Signs and Symptoms met with in Seventeen Cases of Obscure Fever.

No. of Case.	General Appearance.	Symptoms.			Class. ¹	Fever.	Pulse. ²	Tongue.	Spleen.	Spots.
		Headache.	Pain.	Vomiting.						
1	Well	Chiefly morning	Not marked	1st day	O	10 days	Higher	Fairly clean	Large throughout	Present
2	Well	Chiefly morning	Very slight	1st day	O	9 days	Followed T.	Slightly furred	Large throughout	—
3	Toxic	Not marked	Severe in legs	—	C	23 days	Higher	Furred	—	Present
4	Well	Slight	Slight	—	O	8 days	Followed T.	Furred	Large throughout	Present
5	Toxic	Chiefly morning	Very slight	—	C	15 days	Higher	Furred	Large throughout	—
6	Toxic	Slight	Not marked	—	C	19 days	Followed T.	Dry and red	—	Doubtful
7	Toxic	Marked	Not marked	2nd day	C	13 days, swinging type	Lower	Furred	Enlarged 12th day to evacuation	—
8	Toxic	Marked	None after onset	—	C	14 days	Followed T.	Furred	Slightly enlarged 4th to 13th day	Present
9	Well	Very slight	Not marked	—	C	8 days	Followed T.	Dry and red	Slightly enlarged adm. to 17th day	—
10	Toxic	Very slight	Very slight	—	B	Low, irregular	Higher	Furred	Enlarged 3rd to 20th day	—
11	Anaemic	Only at onset	Slight	1st day	B	Normal on 4th day	Slow	Furred	—	—

N.B.—All the patients referred to in the above table had received a triple (T.A.B.) vaccine.

* In Cases 4, 11, and 12 the serological evidence was considered insufficient to warrant a diagnosis of enteric, but as doubt arose they are quoted in full. Case 12 is important, as it was a case of Class A 1 (see previous report) with a typical relapse on the seventh day.

presented no features which clinically differentiated them from the many other cases of obscure fever which have come under observation, and which the pathologist on the results of the agglutination test regarded as free from enteric infection. Here it may be noted, moreover, that in many of the cases in which the agglutination test failed to reveal any evidence of enteric infection the clinical picture more closely simulated that of enteric fever than it did in the 9 cases above mentioned.

It may, perhaps, be necessary to consider briefly the cardinal signs and symptoms of enteric infection as met with at the present time amongst triply inoculated men before referring in detail to those presented by the 17 cases.

A continued fever of a few days' duration, a slow pulse, an enlarged spleen, and a few spots, headache, the toxic

look, and a furred tongue, with, perhaps, some abdominal distension or tumidity, are all more or less constantly met with. None of the 200 cases under observation have presented any abdominal signs or symptoms, but all of the other phenomena mentioned above have been recorded many times among those cases in which no pathological evidence of enteric infection is forthcoming.

In a recent report of the P.U.O. Committee attention has been drawn to the types of temperature now met with in these cases of obscure fever, and the frequent occurrence of an enlarged spleen and the presence of spots has been recorded.

In Table I a summary of the clinical signs and symptoms met with in connexion with these seventeen cases is presented, and the temperature charts show that there is no uniformity in the course of the pyrexias they depict, every

type of chart recorded in the previous report being represented.

The pulse was noted to be regular in all cases, and tended for the most part to correspond with the rise and fall of the temperature; in three cases it was slow, but in the majority it remained at a proportionately higher level than the temperature.

Enlargement of the spleen (palpable spleen) was found in 12 of the 17 cases. The spleen was described as being on the whole larger than that commonly met with in most cases of trench fever, but in a few undoubted cases of the latter disease a spleen equally large and as persistent has been noted. A chart is appended indicating the onset of the splenic enlargement, and its duration whilst under observation.

Spots were detected in 8 cases, and appeared chiefly on the abdomen and the sides of the chest. They were fleecy in character, and apparently identical with the type of spot which is frequently seen in many cases of obscure fever. These spots differ in several particulars from the spots commonly associated with typhoid infections. The latter are described by Osler as

hyperaemic spots which appear from the seventh to the tenth day, usually at first upon the abdomen. They are slightly raised, flattened papules which can be felt distinctly by the finger, of a rose-red colour, disappearing on pressure, and ranging in diameter from 2 to 4 mm. They come out in successive crops, and after persisting for two or three days they disappear, occasionally leaving a brownish stain.

The spots observed in cases of obscure fever vary in number from three or four to 200 or more. They appear as early as the second day or as late as the third or fourth week of the disease, and are found usually on the abdomen, chest, or back. They are pink in colour, are not raised above the surface nor palpable, and disappear in twenty-four hours or less. They vary in size, but are commonly larger than the typhoid spot. Their outline is less regular, and they disappear on pressure.

All the 17 cases complained of pains in the head, for the most part confined to the frontal region and the back of the eyes. Persistent morning headache was a feature in 4 of the cases—a symptom by no means common in cases of trench fever unless a relapse is about to take place later in the day.

Nine of the patients were drowsy and toxic looking, and in 6 cases the toxæmia persisted sufficiently long to warrant a provisional diagnosis of enteric fever being entertained. Many cases of trench fever when seen early present a distinctly toxic appearance, but this they rapidly tend to lose.

In 15 cases the tongue was furred, and in 2 it was described as being red and "beefy" looking. In no case did the tongue remain furred for long. The marked pains in back and shins, which are common in trench fever, were only persistent and severe in 2 cases. All but one of the cases complained to some extent of backache and shin pains, but on the whole their occurrence was not a prominent feature of these cases.

Assuming for the moment that these 17 cases were, as shown by the agglutination test, cases of enteric fever modified in their severity by triple inoculation, and reviewing the clinical observations made on them, it becomes obvious that none of the signs and symptoms recorded, singly or in combination, are in any way characteristic of the disease, and that therefore a diagnosis of this condition based entirely on clinical observation is impossible. How, then, can an enteric

infection be differentiated from the many closely related obscure fevers?

Much has been written of the value of the atropine test associated with the name of Major Marris; more remains to be written when it has been more widely applied by many different observers. Its results in the few cases in which it has been applied in this investigation may be briefly noted. The test was applied in 11 of the 17 cases and was positive in 6 (54 per cent.). The test made on 58 other pyrexial cases in which the agglutination test proved negative was positive in 12 cases (20 per cent.).

The value of the agglutination test as a diagnostic measure may be once more considered. An experience of several hundred cases of pyrexia of unknown origin justifies the conclusion, based on clinical observation, that the vast majority are not due to an enteric infection. A large proportion of them can be identified with that relapsing type of fever which has been described as "trench fever."

In 1915, when McNee and Renshaw, and Hunt and Rankin investigated very many cases of this disease for evidence of enteric infection, they were dealing entirely with a disease as it appeared in men who had received a typhoid vaccine only. In such cases a single agglutination test is sufficient to determine the presence of paratyphoid infection, as the production of any agglutinins for paratyphoid A or paratyphoid B is sufficient evidence of

infection by these organisms, provided that a standardized agglutinable culture is used in making the test.

At the time of their observations, therefore, the diagnosis of paratyphoid fever was a matter of extreme simplicity and precision, but in the large number of cases they examined they found no evidence of its occurrence. Their conclusions, based on an agglutination test less complex and more definite than that of the present time, accord very much with, and confirm, those that have been arrived at in the present investigation.

There are those who may remain unconvinced by the results

of the agglutination test in the 17 cases attributed to enteric infections, and would maintain that the rise in agglutinins shown in Table II is not sufficient evidence of infection.

It may be pointed out that while these cases of obscure fever were under examination, cases more toxic and more severely ill were entering the isolation division of the hospital as cases of "suspect enteric fever." Such cases were investigated in exactly the same manner as were the 17 cases referred to above.

In some of those cases from which the infecting organism was isolated the result of the agglutination test, though perfectly definite, was no more characteristic than many of the results depicted in Table II, and in some was even less striking.

CONCLUSIONS.

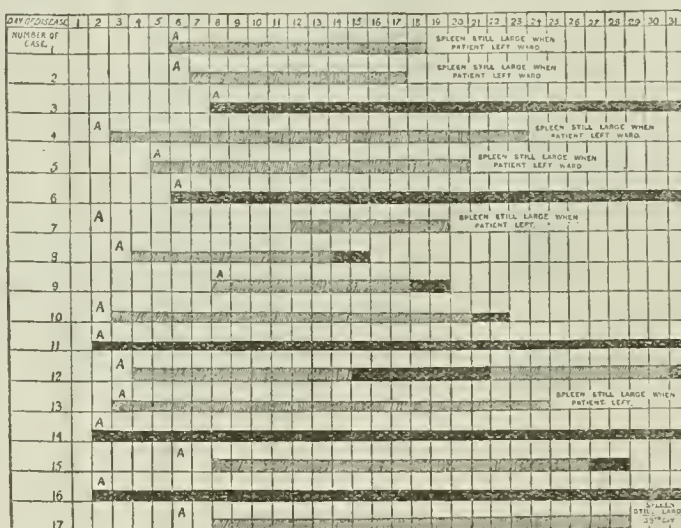

1. Of 200 cases admitted under the diagnosis of P.U.O. or trench fever, 7 or 8 per cent. were proved on serological evidence to be enteric.

2. While in hospital the clinical symptoms of these cases were no more distinctive of enteric than those of many others in which the serological evidence was negative.

3. Bacteriological evidence was never obtained.

PUBLIC HEALTH APPOINTMENTS DURING THE WAR.

We have received from the honorary secretaries of the Society of Medical Officers of Health a copy of the following resolution, passed by the council of the society at its last meeting (January 18th, 1918):

That the Society of Medical Officers of Health deeply regret that local authorities have made many permanent appointments since August, 1914, in the Public Health and School Medical Services. That this society earnestly deprecates such a course being approved by the Local Government Board or the Board of Education, as it is unfair to those men now absent on war service and so penalizes patriotism; further, it is not in the public interest that these responsible posts should be permanently filled at a time when the competition is restricted, and the most able and suitable young men are unable to apply.

A second resolution requested this and certain other journals to refrain from advertising any posts in the Public Health and School Medical Services, except those that are to be filled for the duration of the war, or until six months after the conclusion of peace.

The resolutions are, we are informed, intended to apply to both women and men.

The point raised in the above resolution has not escaped the attention of the British Medical Association. On July 4th, 1917, a letter was addressed to the Local Government Board recalling the terms of the circular issued by the Board to local sanitary authorities in May, 1915, urging them in connexion with appointments of medical officers to endeavour as far as possible, by rearrangement of duties among other officers, to avoid making any fresh appointment during the period of the war, or, failing that, to arrange for the work being carried on for the period of the war by practitioners engaged temporarily. After expressing the appreciation with which the Association and the profession generally had regarded the attitude thus taken up by the Board, the Association inquired whether certain then recently made appointments had been sanctioned as permanent. Two specific appointments believed to be permanent were mentioned, and the Local Government Board, in a reply dated July 16th, stated that these two appointments had been sanctioned permanently by the Board, the one having been made on July 8th, 1915, and the other on January 4th, 1916. The Board, however, added that about the middle of January, 1916, it had limited the sanction of appointments of medical officers of health to the period of the war and had continued that practice since. The matter will be further considered by the Public Health Committee of the British Medical Association at its next meeting.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Wounded.

Captain J. T. Heffernan, R.A.M.C. (temporary).
Captain F. W. Tidmarsh, Canadian A.M.C.
Captain H. C. Trumble, Australian A.M.C.

MEDICAL STUDENT.

Hendry, P. G., Gunner, Royal Garrison Artillery, third son of the Rev. P. G. Hendry, of Paxton, Berwickshire, medical student, Edinburgh University, accidentally killed, February 6th.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SPECIAL Supplement to the *London Gazette*, issued on March 4th, contains a list of rewards for gallantry and distinguished service in the field. The acts of gallantry for which the decorations have been awarded will be announced later in the *London Gazette*. The following medical officers are included in the list:

Bar to the Military Cross.—Temporary Captain G. L. Thornton (M.C. gazetted January 1st, 1918).

Military Cross.—Temporary Captain R. D. Bell, R.A.M.C.

A bar to the D.C.M. has also been awarded to a non-commissioned officer of the A.A.M.C., and the D.C.M. to nine non-commissioned officers and two privates of the A.A.M.C., and to eight non-commissioned officers and two privates of the R.A.M.C.

The following officers of the R.A.M.C. are included in a further list of names recommended for distinguished and

gallant service and devotion to duty in the dispatch from the Field-Marshal Commanding-in-Chief the British Armies in France dated November 7th, 1917: Temporary Captains H. D. Field (died of wounds), and K. T. Limbery (killed).

The names of the following officers are as now stated and not as notified in the list of mentions in dispatches published in the Supplement to the *London Gazette* of December 24th and December 28th, 1917 (BRITISH MEDICAL JOURNAL, January 5th, 1918, p. 32): Captain (Acting Lieut.-Colonel) C. S. Brebner, M.D., R.A.M.C.; Captain E. O. Watson, A.A.D.C.

England and Wales.

THE TREATMENT OF TUBERCULOSIS.

At the meeting of the London Insurance Committee on February 28th it was stated that 459 persons were receiving sanatorium treatment, and 357 awaiting it. Owing to the large number of discharged tuberculous soldiers requiring residential treatment, the Committee was finding considerable difficulty in obtaining accommodation; about 120 ex-soldiers were in the sanatoriums, and 140 on the waiting list. Dr. Noel Bardswell, the Committee's medical adviser for sanatorium benefit, suggested that a number of country houses should be secure and adapted to the requirements of small sanatoriums. The policy had been reluctantly adopted of shortening the average length of treatment in a sanatorium instead of exercising greater rigour in the selection of cases for benefit; the condition of affairs was still far from satisfactory. The Committee resolved that extra nourishment should be given as a part of domiciliary treatment of tuberculosis, only with the approval of the Committee's medical adviser and only to patients who were awaiting admission to an institution, or who had recently been discharged and were returning to employment.

MILK FOR CHILDREN AND MOTHERS.

The Local Government Board has issued a circular letter to county councils and sanitary authorities with reference to the Milk (Mothers and Children) Order, February 8th, 1918, the effect of which was stated in the JOURNAL of February 23rd, p. 242. The letter calls the attention of medical officers to the importance of doing nothing to favour the abandonment of breast feeding. The quantity of milk which may be ordered to be supplied at less than cost price in ordinary cases has been determined by the Food Controller as follows:

(a) For children under 18 months, not more than one and a half pints daily. (b) For children between 18 months and 5 years, not more than one pint daily. (c) For expectant and nursing mothers the quantity specified by the officer referred to in this paragraph. If dried milk or preparations of milk are used the quantity should be such as would, when properly reconstituted, approximate to the quantities of fresh milk given above.

The definition of "necessitous cases" is left to the discretion of the authority, but it is stated that in some districts a scale has been adopted, based on the income of the family, after taking into account the number of children. The Ministry of Food notifies that it has purchased a large quantity of full cream dried milk suitable for infant feeding, and a quantity of half cream dried milk, and is prepared to receive application from medical officers of health, infant welfare centres, and other similar institutions, for a supply at cost price. In arranging dinners for expectant and nursing mothers the local authority must act in consultation with the Local Food Committee in respect of any food which is subject to an order of the Food Controller or of the committee.

Scotland.

EARLY TREATMENT OF MENTAL DISTURBANCES DUE TO WAR STRAIN.

In his report for 1917 on the Royal Edinburgh Mental Hospital, Morningside, Dr. George M. Robertson has a story to tell very similar to that he told last year. There is no evidence that since the outbreak of the war the amount of insanity has increased, and among the working-class population in the district from which patients are drawn by Morningside there has been a decrease, most

marked in regard to men, and mainly due to the absence of so many of the younger on military duty. The strain of the war has been the exciting cause of much insanity among them, but the vast majority are being dealt with by the military authorities. Among women, though there have been many cases of mental breakdown from excitement, overwork, worry, and anxiety, on the whole the strain produced by the war has not resulted in an increased amount of insanity. It is suggested that the higher wages earned and the separation allowances regularly received have relieved domestic worries and uncertainties. Alcoholic excess was assigned as the direct or exciting cause in 15½ per cent. of the male admissions—slightly less than the average for the seven years before the war. As to alcoholic excess as an indirect or predisposing cause among men, it appeared that the legislative restrictions upon the sale of alcohol were mainly to be credited not only with the slight improvement which has taken place, but with the defeat of the operation of the rule that increased wages are associated with an increase in drunkenness. With regard to women, the amount of insanity attributed directly to alcoholic indulgence was under 3 per cent., or about one-third of the average for the seven previous years.

In a section of his report dealing with shell shock and war strain Dr. Robertson pointed out that the most marked nervous disorders were least frequently met in the firing line. Emotional disturbances and consequent states of confusion might occur there, but they were evanescent. If they were followed by an interval of calm, known as the "phase of contemplation" or the "period of meditation," then the more marked disorders might develop. If taken in hand at once close to the firing line they rapidly vanished under the influence of suggestion. If allowed to become established as a habit, the cure became much more difficult, but the same methods were ultimately successful at the base. Dr. Robertson said that in what he termed the incubation stage the mind, owing to a morbid suggestibility following on the emotional disturbance, instinctively but involuntarily fastened on some idea which expressed itself in a nervous disorder—loss of voice, or hearing, or sight, or the power of speech, or difficulty of breathing, or of standing, or walking, or paralysis of many kinds.

In discussing the importance of providing facilities for treating mental disorder in its earliest stages, Dr. Robertson said that public opinion was growing more averse to sending persons suffering from short and recoverable attacks of insanity to asylums, "as thereby not only does a certain stigma, unjust though it be, attach to them, but they also require to be legally certified as lunatics." The problem arose at Morningside in connexion with Craig House, a separate establishment for private patients. There was a consensus of opinion that a simple increase of asylum accommodation, by the erection of one or two more villas within the grounds, was not the most desirable way of meeting an urgent want. Therefore the proposal was made to provide nursing homes, not in the grounds, in which patients suffering from the early stages and the curable forms of mental disorder could be separately treated without the necessity of certifying them. A provision of the Scottish lunacy laws enables patients of the classes described to be kept for six months in nursing homes with a view to their recovery, but certain doubts as to the interpretation of the law caused delay. It has, however, been possible at once to make the experiment for officers suffering from the more serious effects of shell shock and war strain. With the assistance of the military authorities homes for them were established outside the boundaries of Morningside, but under Dr. Robertson's supervision. He goes on to observe that there is no essential difference between the case of the soldier who becomes insane in the defence of his country and that of a woman who suffers from an attack of puerperal mania, and that it is an injustice not to accord to the civilian privileges similar to those which have been provided for the officer. He draws the following conclusion:

The medical treatment of mental disease must be freed from all unnecessary legal shackles and indignities. The question is no longer a theoretical one, but an urgent practical one. In view of what has been done for soldiers, medical men will not accept the assertion that the adoption of similar measures is impossible for their patients. It is intolerable that the lives and happiness of people at the present day should be marred by

a certain interpretation of an Act sixty years old, suitable for conditions of society which are now non-existent, yet determining present-day views and problems of medical treatment which were unthought of when our forefathers passed the Act. The law very properly is not in advance of public opinion, but it is in a most unwholesome condition when it lags so far behind as do some of the procedures in lunacy.

Ireland.

POOR LAW MEDICAL OFFICERS' SALARIES.

THE medical officers of the Enniskillen union, having been refused an increase in their salary on three different occasions by the board of guardians, tendered their resignations, to take effect from February 19th. The guardians, by thirty-seven votes to seven, decided that they would not consider the doctors' applications until they withdrew their "threatening notice." The result is that, owing to the high-handed action of the guardians, the poor of the Enniskillen union have now no doctor whose duty it is to afford them medical relief, and are altogether dependent for their medical treatment on the humanity and charity of the doctors who resigned because the board of guardians did not consider them entitled to the wage of a farm hand. The Irish Committee of the British Medical Association some time ago took legal advice as to the powers of the Local Government Board to fix the salaries of the Poor Law medical officers. In the opinion of the solicitors consulted there is very little doubt that Section 8 of the Medical Charities Act, as amended by the Local Government Board, 1898, gives the Irish Local Government Board power "when they see occasion from time to time to regulate the amount of salaries or allowances payable to such officers respectively." It is believed that the Local Government Board, in the interests of the sick poor, for whose medical treatment it is responsible, cannot much longer defer interference in order to fix the salaries of Poor Law medical officers. In one Irish union a dispensary doctor for his services may receive £100 a year, whilst in another union, for doing possibly less work, another dispensary doctor may be in receipt of £200 per annum. Even the larger salary of £200 is totally inadequate and, at all times, was much below the working expenses of the average Irish dispensary district with an area of twelve miles square.

LOCAL GOVERNMENT BOARD AND EXTERN PATIENTS.

At a recent meeting of the Dungannon guardians the clerk said that the medical officer had certified that, in his opinion, a patient from Coalisland should be sent to the Samaritan Hospital. The case was developing very seriously, and should have immediate special treatment, and perhaps go through a serious operation. In view of the recent decision in the King's Bench (Dublin) that only destitute workhouse inmates could be sent, at the cost of the rates, for treatment at extern hospitals, the clerk wrote to the Local Government Board, which replied that if the guardians decided to send this woman for special treatment, as recommended by the medical officer, and, if a surcharge should subsequently be made, full consideration would be given to any appeal for remission thereof.

Correspondence.

SANATORIUM TREATMENT OF THE TUBERCULOUS SOLDIER.

SIR,—I agree with your correspondent (March 2nd, p. 272) that it is high time that some really practical and effective scheme for the treatment of soldiers and sailors suffering from tuberculosis should be formulated and put into practice. To be effective, any rational scheme must be, as far as possible, immediate in its effect, continuous in action even for several years, economical and convenient; but, above all, it must be designed so as to benefit the great majority of sufferers. Since sanatorium treatment can never benefit 10 per cent. of the sufferers, responsible authorities must look about for some alternative method. The alternative system must rely upon those discoveries of science which have banished typhoid fever from our armies and prevented thousands of deaths from tetanus.

Most of the critics of the value of tuberculin as a diagnostic and curative agent base their views on second-hand opinion. Tuberculin has never had a fair trial. Surely now is the time for a trial. I dare to say, on the strength of very extensive experience, that the diagnosis of early tuberculosis by specific methods when other methods fail and the treatment of tuberculosis in early and even late stages by various forms of tuberculin will revolutionize our present methods of dealing with the problem of tuberculosis. I ask for such a trial on behalf of these afflicted sailors and soldiers. It will be found that not only will thousands gain some respite from the sad fate that surely threatens them, but even tens of thousands will be restored to relative, and many thousands also to apparently absolute, health. The medical authorities at the War Office would do a great national service by appointing a small committee of experts to consider the problem from this aspect.—I am, etc.,

W. CAMAC WILKINSON, M.D., F.R.C.P.,
Pathologist, Bermondsey Military Hospital.

London, W., March 5th.

GENERAL ANALGESIA BY ORAL ADMINISTRATION.

SIR,—Dr. Gwathmey is so careful in his statements and so modest in his claims that as a rule he leaves little to criticize. In his contribution to the *BRITISH MEDICAL JOURNAL* of March 2nd (p. 254), however, he makes one statement which is surely too sweeping, when he says:

A 65 per cent. solution of ether in oil has been used in many thousands of cases of oil ether colonic anaesthesia without any sign of local irritation . . . as has been proven . . . by the fact that no case of dysentery or bloody diarrhoea has been observed.

Dr. Gwathmey may only be referring to cases in his own practice or within his knowledge. He appears to have been fortunate, as I should think there are few hospitals in which this method has been tried that have not had at least one or two cases of post-anaesthetic dysentery and bloody diarrhoea.

I was probably one of the first in this country to give the method a trial, but, whilst fully realizing its value in certain cases, it was the occurrence of these symptoms in one of my earlier cases that led me to reserve its use for very special occasions, with the result that between 1913 and 1917 I did not once avail myself of it.

The oral administration appears to answer very well for painful dressings, but I cannot think it will come into vogue for operations for which patients must be removed to the theatre. What strikes me as truly wonderful is that the analgesia is produced without any preliminary excitement or ill after-effects.

Is it quite certain that this method of analgesia is safer than anaesthesia? We want the results of a few thousand cases for purposes of comparison, say, with open ether.

Finally, I should not feel on perfectly safe ground if I introduced a drachm of chloroform into a patient's stomach. Granted that absorption is regular and slow and elimination constantly going on, well and good; but may there not be individuals who absorb rapidly and fail to eliminate? If so, I can imagine trouble when some 30 or 40 minims were circulating in the blood.—I am, etc.,

London, W., March 5th.

G. A. H. BARTON.

TRANSFUSION OF PLASMA.

SIR,—I have been reading with interest recent articles in the *JOURNAL* on blood transfusion in casualty clearing stations. Apparently one of the chief troubles is the question whether or not the recipient's plasma will haemolyze the corpuscles of the donor.

Surely this difficulty might be avoided by not transfusing the corpuscles at all, but only citrated plasma, which would be easy to keep and easy to give. There is abundant clinical and experimental evidence that it is not the corpuscles that are wanted, but the ideal fluid for keeping blood pressure at its proper level, and the apparent advantage of blood is, no doubt, due to its permanent value in this respect and to its food value. A man apparently dying from haemorrhage is not dying from lack of haemoglobin, else severe cases of anaemia would die long before they do, but from draining away of fluid, resulting in devitalization and low blood pressure.

May I at least recommend a trial of this method, controlled, let us say, by an equal number of whole blood

transfusions and an equal number of gum acacia (not less than 6 per cent.) cases?—I am, etc.,

GORDON R. WARD,
Sevenoaks, March 3rd.
Captain R.A.M.C.(S.R.).

THE TREATMENT OF WOUNDS BY FLAVINE.

SIR,—Major Pearson, in the *BRITISH MEDICAL JOURNAL* of March 2nd (p. 271), in commenting on Colonels Pilcher and Hull's favourable report on 5,000 cases, has summarized his experiences to the effect that "no substantial differences were observed between flavine and the other substances in regard to the control of sepsis." He employed flavine in the form of gauze "wrung out in 1 in 1,000 solution." His results are not surprising in view of the fact that the gauze was wrung out. The "advocates" of flavine have recommended the use of gauze soaked in flavine solution—a very different thing. As regards the point whether flavine should often be intermitted or discontinued in the later stages of wounds, this was suggested in our second report (*BRITISH MEDICAL JOURNAL*, July 21st, 1917), and has been borne out by the work of Drummond and McNee;¹ see also Browning and Ligat,² and Carslaw.³—I am, etc.,

London, W., March 2nd. C. H. BROWNING.

SUPPLY OF ARSENOBENZOL DRUGS TO GENERAL PRACTITIONERS.

SIR,—Syphilis is spread very largely by girls who are not prostitutes, and who often do not know that they have been infected. In practice they do not go to the venereal clinics even when they know or suspect that they are infected; they are partly ashamed to go, and then in the provinces the clinics, based as they are on the larger general hospitals, are often a long way off, and the patient not only has to lose a day's work in order to attend, but subjects herself to the malignant gossip of a small ignorant community if she does.

If they consult anybody but that harmful person the prescribing chemist, it is to a private practitioner they turn, but he cannot obtain a supply of salvarsan or its substitutes from the local authority unless he has himself attended a course of instruction at a venereal clinic, or otherwise demonstrates his familiarity with the administration of the remedies by intravenous injection. But, as Colonel Harrison has shown, these preparations can be given with equal efficacy intramuscularly, a method which requires no special skill. What is wanted, therefore, is that remedies for intramuscular use should be supplied by the local authority free of charge to any practitioner for use in cases that would otherwise come under the aegis of the venereal clinic. Along with the "amateur" we must class those cases of syphilis insontium who could not be driven to any public institution. The two taken together constitute a fertile source of infection not being adequately if at all combated by the regulations as they at present stand.—I am, etc.,

Sheringham, March 4th.

A. KNYVET GORDON.

HEALTH AND ECONOMICS.

SIR,—During the war it has been wrong, if avoidable, to use the telephone, telegraph, or parcels post; all are being run at a loss, and to use them is to increase the country's burden. Thus enterprises which in private hands were, and would now especially have been, great national assets have become great national liabilities. In a word State management has wrought national harm out of national good.

In 1912-13 the State undertook the treatment of the poor and of a caste it included in the poor. In four years tuberculous mortality has risen by 12 per cent. The figures do not wholly present the gravity of the case. By 1915, for a population largely reduced by the subtraction of the forces, the absolute number of tuberculous deaths had largely increased. The M.O.H. for Manchester has pointed out that in his district the fatality among the poor began to increase in 1913; it is scarcely doubtful that the mortality among the well-to-do is on the decline; therefore it follows that the process in the Manchester district is a general one, and even more than a 12 per cent. rise must have taken place among the special protégés of the Commissioners.

¹ *Lancet*, October 27th, 1917.

² *Ibid.*, November 17th.

³ *R.A.M.C. Journ.*, October, 1917.

It is another lesson, which should surely not have been needed, that whatever, outside its proper province, the cruel, stupid hand of State touches, it blisters. Remember that this rise was predicted. No man can, without bias, compare the wage-rate and tuberculosis curves as far back as we can go, having an eye on the history of the times, without asking himself whether it is not the constructive legislation "for the good of the poor" that is to blame for this dreadful result. All are agreed on the importance of environment—that is, of the economic factor. What is the good of prattling about environment when every remedy you suggest is a blow to the value of wages, that factor in environment which given, involves, which denied, negatives, all other factors? But I think that few realize how sensitive an index of economic conditions is the tuberculosis death-rate. Just as extraordinary falls in the rate reflect Peel's first free trade measures, the repeal of the Corn Laws, the repeal of the Navigation Acts—so all the great wars, sometimes even a group of little ones like the Zulu and Afghan, leave their mark in an upward fluctuation some two or three years after.

It is certain that real wages and tuberculosis mortality are in inverse ratio; equally that wages vary inversely with prices or taxation. As under Walpole, so under the Manchester school, with its corollary Gladstonian finance, wages rose steadily beyond all previous records. Under the latter we know that the tuberculous death-rate fell steadily and so rapidly that had the decline continued till to-day at the same rate the mortality would only have been half of what it is. But after 1896 wages began to fall in value. The mortality still declined, but more slowly. In 1913 the Insurance Act began to be operative. Though it has much work yet to do in that way, it has already lowered the value of wages, probably more than anything since the Corn Laws; the tuberculous death-rate began forthwith to rise.

It needed no great foresight to predict this result; it did and does need an obsession to be blind to its possibility. No one would question that a war which left on the country a capitalized burden of £400,000,000 would affect the tuberculous mortality. But the burden of the Act must be as much as that at the very least; and in its effect on the poor you must add, not subtract, the premiums which would have been paid, Act or no Act: for voluntary insurance increases wages.

Is the Association to stand by and see these men die without criticism or inquiry because, forsooth, it is a politician's matter? As if a doctor should suspect a wife of poisoning her husband and refuse to inquire because he has nothing to do with conjugal relations. Besides, our leaders are interfering with politics; when they urge the present formation of a Ministry of Health, they are corroborating the fashionable policy of making the poor poorer, in order to maintain officials who shall inquire into and gloss over the effects of poverty. On men dying of already too many officials, they propose—at this time of all times!—to let loose another horde. Well might Sir William Chance tell them that England was going mad. As representing a science, they have nothing to do with politics; they have all to do with facts. Explain it how you will, *laissez faire* from the public health point of view was a brilliant success, State collectivism is a dismal failure. If the policy of which the National Insurance Act is the supreme expression is really killing off the poor, and the leaders of the Association do not inquire, they have forfeited the right to speak for a profession which has made it its legitimate boast that it has put the public welfare before all other things.—I am, etc.,

Rayleigh, Essex, Feb. 24th.

B. G. M. BASKETT.

FORMS AND REFORMS.

SIR,—Your article, "Forms and Reforms," in a recent number of the JOURNAL was no doubt intended to be a composite picture. It is, however, a description, almost photographic in its accuracy, of the conditions prevailing in a military hospital in which I served for the greater part of last year. If you had added the want of courtesy displayed by those in administrative authority towards civil practitioners who, at the urgent call of the War Office, had offered their services to the country, the picture would have been complete.—I am, etc.,

March 5th.

LATE CIVIL SURGEON.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE Degree Committee of the Special Board for Medicine announce that the work submitted by J. E. M. Mellor, entitled "Research into the habits of flies in relation to the public health," is of merit as a record of original research. The Special Board for Medicine has formulated regulations for the Nita King Research Scholarship on Fevers.

UNIVERSITY OF LONDON.

UNIVERSITY COLLEGE.

THE annual report for the year ended February, 1918, shows that whereas in normal times the total number of students (day and evening) amounted to about 2,200, the number last session was 1,240; but of these 121 were members of the naval and military forces for whom special courses were provided, and 159 attended special vacation courses, so that the actual number of ordinary students was 960, of whom 547 were women. The total number of day students registered is 758. This includes 12 refugee students; deducting these, the total is 746, a decrease of 96 in the year, and of 598 as compared with the corresponding date in 1914. The number of medical students shown is 63 (all men, and including two refugee students), but during the year it was arranged to admit women students to the courses for the second examination for medical degrees and of the Conjoint Board. For many years women students have attended the courses for the first examination for medical degrees, but have been obliged to go elsewhere for the remainder of their medical course. Under the new arrangement they can take at the College the medical course up to the second examination—that is to say, the whole of the course given at the College as distinguished from the medical school. Twenty-one women students are attending the medical courses in the College during the present session. The new revised list of past and present members of the College who are taking an active part in one or other of the services connected with the war, containing 2,500 names, will shortly be issued. Of these no fewer than 195 have fallen. The list of honours received is long, and includes one Victoria Cross and a clasp to the Victoria Cross.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Election of Council.

IN accordance with the new regulations to enable Fellows of the College beyond the United Kingdom to vote at the annual election, the secretary of the College issued on March 8th a circular letter to the Fellows informing them that a meeting of the Fellows will be held at the College on Thursday, July 4th, at 2.30 p.m., for the election of four Fellows into the Council in the vacancies occasioned by the retirement in rotation of Sir W. Watson Cheyne, Bt., K.C.M.G., C.B., M.P., Mr. Bilton Pollard, Sir John Bland-Sutton, and Mr. Walter Spencer. Blank forms of the requisite notice from a candidate of his nomination may be obtained on application to the secretary, and must be received by him, duly filled up, not later than March 18th. A voting paper will be sent by post to each Fellow whose address is registered at the College on Tuesday, April 2nd. We understand that Sir Watson Cheyne will not seek re-election.

The Services.

TERRITORIAL DECORATION.

THE Territorial Decoration has been conferred upon Major H. Legh de Legh, M.D., and Major James L. Loudon, both of the R.A.M.C.(T.F.).

Obituary.

C. R. STRATON, F.R.C.S. EDIN.

WILTON.

WE regret to record the death on February 22nd, after a long illness, of Mr. C. R. Straton, of Wilton, near Salisbury. He was the son of Mr. Charles Straton, W.S., of Edinburgh and New Brunswick, and was born in Edinburgh in 1842. For some time he followed his father's profession, but afterwards determined to adopt medicine and received his medical education at Edinburgh, obtaining the diploma of L.R.C.P. Edin. in 1866; in 1882 he became F.R.C.S. Edin., and in 1889 L.S.Sc. Durh. He gained distinctions all through his studies, both in law and medicine, and was house-surgeon to Lord Lister in Glasgow, and remained his friend. He joined his uncle in practice at Steeple Langford for a time, and then settled in Wilton, where he enjoyed a large practice and the confidence and respect of the public throughout South Wiltshire. He was appointed

medical officer to the Wilton district and workhouse, holding the former appointment for forty-five years. He was medical officer of health for the Wilton Rural and Urban Districts, and certifying factory surgeon, and was a visitor of the Fisherton and Laverstock lunatic asylums. He was an active member of the committee of management of the Salisbury Infirmary and of the Salisbury Nursing Home, and an organizer of the Salisbury Public Medical Service. He took an active part in the work of the district, was three times mayor of Wilton, was a director of the Wilton carpet factory, and shared in every local enterprise or institution from the diocesan synod to charity organization and the local War Savings Committee.

Mr. Straton was long a member of the British Medical Association and took an active share in its work. He was president of the Southern Branch in 1900 and vice-president of the Section of Public Health at the annual meeting at Sheffield in 1908. He was for many years a member of the Council of the British Medical Association, served on the Parliamentary Bills Committee, and afterwards on the Central Ethical and Insurance Acts Committees.

He had many interests outside medicine and public work. He was a Fellow of the Entomological Society and an authority upon oak galls and gall flies; he translated Adler's book on *Alternating Generations* (1894) from the German and added valuable notes upon English varieties. He gave attention to every department of natural history and for nearly half a century was an indefatigable worker in the South Wilts and Blackmore Museum, acting as curator of natural history. He was a member of the Salisbury Field Club, of the Wiltshire Archaeological Society, and of the Salisbury Microscopical Society. He often lectured upon his favourite subjects, chiefly at the Salisbury Museum, but also at Haslemere.

A piece of work which took him seven years to complete, and one by which his name will always be remembered by historians, is the *Survey of the Lands of William, 1st Earl of Pembroke*, published in 1909 by the Roxburgh Society in two fine quarto volumes. It involved a transcription from the original parchment rolls of the sixteenth century, in the crabbed and contracted monastic Latin of the period, and a translation. He prefixed to it an essay on the life and administration of a great manor, which produced on the reader a very strong impression of his learning, breadth of view, and powers of description.

He married in 1875, but his wife died twenty years later. He leaves four sons, of whom three are either now serving or have served during the war as officers in the R.A.M.C. The fourth, a private, is serving in a garrison regiment.

At a meeting of the Wilton Town Council and board of guardians appropriate tributes to Mr. Straton's memory have been paid. The funeral, which took place at Wilton, was attended by a large number of friends and representatives of various bodies, the British Medical Association being represented by Dr. Harman and the Salisbury Division by Dr. Willcox.

WE regret to announce the death of Dr. GRACE R. CADELL on February 19th at Mossbank, Rumbling Bridge. After obtaining the triple qualification Scotland in 1891 she held the post of surgeon to the Edinburgh Hospital for Women and Children, was consulting obstetrician to the Hospice, Edinburgh, and later became registrar at the New Hospital for Women, London. Dr. Cadell took a keen interest in woman's suffrage, and had been a militant suffragist.

DR. A. HAMPTON BREWER, who died on January 28th, at the age of 75, was one of the oldest and most respected of Hackney practitioners. He received his medical education at St. Bartholomew's Hospital, where several generations of his family had studied, and where his uncle, Dr. Henry Jeafferson, was senior physician. After taking the qualifications of M.R.C.S. and L.S.A. in 1864, and L.R.C.P. in 1865, he acted as assistant for two years to a Wokingham practitioner, and then joined Dr. Jones of Dalston, whose daughter he subsequently married. He soon got together a large private practice, and was long associated with the Provident Department of the Metropolitan Hospital, the success of which was largely due to his energy and enthusiasm. Dr. Brewer had much wished

to complete fifty years of practice at Dalston, but about a year before this period was reached his health had failed, and, in deference to medical advice, he retired at the close of 1917, and spent the last months of his life at his country residence in the Isle of Wight. His professional work was his chief interest in life, but he had several hobbies, such as poultry breeding, gardening, and carpentering. In his youth he was a great athlete, and remained to the end fond of sport of all kinds. Once as a student he walked from London to Bristol in four days. Dr. Brewer took little share in politics of any kind, but his opinion on public questions was much sought after and respected. His death is deplored by a wide circle of friends and patients. Five of his six sons joined the army in the present war; two of these took commissions in the R.A.M.C., and the youngest lost his life at Gallipoli.

Medical News.

THE Ministry of National Service has issued revised general directions for the guidance of Commissioners, Deputy Commissioners, and members of medical boards.

THE number of certified midwives who have given notice of their intention to practise within the county of London during 1918 is 554, a decrease of 25 on the number for the previous year.

Lieut.-Colonel Thomas Wallis, M.D., and Colonel J. Arnall Jones, M.D., have been appointed treasurer and almoner respectively of the new priory of the Order of St. John of Jerusalem, established for the principality of Wales and the county of Monmouth.

THE Minnesota State Pharmaceutical Association has issued a paper on war emergency formulas by Mr. F. A. Upsher Smith, chairman of its committee on dispensing. The paper contains suggestions for economy in the use of glycerin, sugar, and alcohol. The secretary, Dr. E. L. Newcomb, to whom we are indebted for a copy, observes that the recommendations as to the substitution of fresh infusions for alcoholic fluid extracts, tinctures, and elixirs, and the prescribing of salts, such as the bromides, in the form of a slightly flavoured mixture in place of an elixir, would very often tend to benefit patient, physician, and pharmacist.

THE Medical Research Committee has appointed a special committee to consider the methods of manufacture, biological testing, and clinical administration of salvarsan and its substitutes used in this country, and the results of these, and to propose to the Medical Research Committee specific investigations aimed at improving those methods and results. The Committee consists of Dr. H. D. Rolleston, C.B., temporary Surgeon-General R.N. (chairman), Professor F. W. Andrewes, M.D., F.R.S., Professor Wm. Bulloch, M.D., F.R.S., Dr. H. H. Dale, F.R.S., Lieut.-Colonel L. W. Harrison, D.S.O., R.A.M.C., and Dr. F. J. H. Coutts, Assistant Medical Officer, Local Government Board (secretary). The Committee is arranging to invite the assistance of others who are in a position to offer evidence or advice towards the solution of particular problems arising within the scope of this inquiry.

THE annual reports of the school medical officer for London since 1914, based upon an annual examination of some 200,000 children, have indicated an all-round improvement in the physical condition of the children during the war; that the number of children found at medical inspections to be under-nourished greatly decreased. The results for 1917 show that the improved conditions were fully maintained. During the third term of 1917 the inspection of all the entrant children, which had been discontinued from the beginning of 1916, was resumed, and the results of this term's examinations were the best that had ever been attained; the percentage of children found in a poorly nourished condition was considerably less than half the percentage so found in 1913.

AT a meeting of the Llandudno Season Extension Committee, when Dr. E. R. Woodhouse was in the chair, the possibility of making the place a winter resort was discussed. Dr. Parry-Edwards, County M.O. Carnarvonshire, said that Llandudno had a high average of bright sunshine—1,600 hours a year; in the month of March, the worst at Llandudno, the maximum temperature for eight years was 48° F., the minimum 38°, and the mean 43°; the average rainfall was not high—32 inches. The death-rate was low—11 per 1,000—as was also the infant mortality, 92 per 1,000. He wound up by suggesting that means should be taken for bringing the Trefriw waters to the town. The Trefriw spring in the Conway Valley is a very strong chalybeate water, in which the iron occurs as proto-sulphate.

Letters, Notes, and Answers.

Authors desiring reprints of their articles published in the *British Medical Journal*, are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *British Medical Association and Journal* are:

1. EDITOR of the *British Medical Journal*, *Atiology*, *Westrand, London*; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate, Westrand, London*; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Mediscera, Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the *British Medical Association* is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

Queries, answers, and communications relating to subjects to which special departments of the *British Medical Journal* are devoted will be found under their respective headings.

LETTERS, NOTES, ETC.

THE following appointments of certifying factory surgeons are vacant: Burghhead (Elgin), Newport (Isle of Wight), Fethard (Tipperary).

DR. C. N. FOLEY (10, Tollington Park, N.4) writes to say that he has held the appointment on and off for eleven years of medical officer to the Falkland Isles Co., Limited, and would be pleased to give any information to intending applicants for this post if they would care to communicate with him.

THE NIGHT SCREAMING OF CONGENITAL SYPHILIS.

In a note (p. 248) reference was made to this subject, which has attracted the attention of many physicians since Eustace Smith first indicated its diagnostic significance. An x-ray photograph demonstrated by Dr. Cameron in a recent clinical lecture (*Guy's Hospital Gazette*, July, 1917) affords an explanation of the cause of the screaming in at least some cases. The skiagram was obtained from an infant six weeks old, one of male twins. There was no other sign of syphilis save a slight tendency to snuffles and a little pallor, which became significant when comparison was made with his twin brother, who showed no signs clinically of congenital syphilis, though, like his brother and mother, he gave a positive reaction to the Wassermann test. The mother brought the child for pain in the legs, and it was possible to palpate a thickening near the right knee-joint. The skiagram showed marked periosteal overgrowth. Dr. Cameron spoke of the case as periostitis and epiphysitis of congenital syphilis, or "syphilitic pseudo-paresis." He called attention to the difficulty of appreciating the precise situation of tenderness in a baby, and observed that the mother has generally better opportunities for observation, so that it is well to pay attention to her opinion, if she is sure that the arms or legs are tender on movement.

WAR PHOTOGRAPHS IN COLOURS.

AN exhibition of official war photographs, organized by the Ministry of Information, was opened at the Grafton Galleries, London, on March 4th. It consists for the most part of greatly enlarged colour photographs of scenes on the Western and Eastern fronts. The pictures are strikingly realistic, and illustrate many phases of life, suffering, and death in the battle area. A considerable number have a strong medical interest. We see wounded men being carried on stretchers across a shell-pitted field; British and German wounded lying side by side on stretchers; German walking wounded pouring into an advanced dressing station after the battle of Menin Road; a stretcher case at an aid-post, with his rifle as a make-shift leg splint; a remarkable silhouette of a wheeled stretcher and bearers; foot inspection by the battalion medical officer in a front line trench; a parade of walking wounded at a field ambulance; and several scenes in hospital. There is also a photograph of a shell bursting close to an advanced dressing station, over which floats unheeded the Red Cross flag. Among the more gruesome pictures are large reproductions of dead Germans and of the carcasses of horses beside a desert track. We could wish that the catalogue of this remarkable exhibition had not been composed in the style of the popular illustrated daily, with its mixture of bombast and facetiousness.

THE STERILIZING OF HYPODERMIC SYRINGES.

DR. P. J. FINEGAN (Carlingford) recommends the following method of sterilizing hypodermic syringes, which he learnt from Dr. Rankin of Belfast: The metal fixture for holding the syringe in its case is placed in the upturned metal case cover with 2 drachms of methylated spirit. The metal hypodermic syringe case, three-quarters full of water, is placed on the fixture with syringe and one needle, and the

methylated spirit lighted. In a few minutes the syringe is sterilized; if warm water is used 1 drachm of methylated spirit will be sufficient.

EMERGENCY RATIONS OF VARIOUS ARMIES.

THE emergency ration adopted by the United States army about twenty years ago consisted of biscuit, bacon, pea-meat, and coffee, and was calculated to yield 4,110 calories; it included also salt, pepper, and tobacco. We learn from the *New York Medical Journal* that a new emergency ration has been devised composed of wheat flour, meat, and dried milk compressed to about the size of a dog biscuit; some pea-nut butter in a paraffined packet is added, and the whole enclosed in a sealed waterproof wrapper; the weight is about 4 oz., and the nutritive value 2,400 calories. The American army also had a "travelling ration" consisting of bread, canned beef, beans, tomatoes, coffee, and sugar, calculated to yield 2,735 calories. The emergency ration of the French army consisted of biscuit, rice, dried vegetables, meat, soup, salt, sugar, and coffee. It was made up in packages for two days, yielding from 2,130 to 2,515 calories, according as to whether the soup was made with bean or pea-flour. The emergency ration of the German army consisted of field biscuit and tinned meat, preserved vegetables, coffee, and salt. It was calculated to yield 2,766 calories, and each soldier carried two. The emergency ration of the British army used to consist of four cakes of chocolate with some dried milk protein. It was wrapped in vegetable parchment paper and packed in a hermetically sealed tin; the ration weighed 6½ ounces net.

THE OLDEST ENGLISH HOSPITAL.

MR. D'ARCY POWER has published in the *Journal of St. Bartholomew's Hospital* a mid-seasonal address he gave last December, which is a kind of historical dream of the hospital, and the best of his in that vein which we remember. If Rahere's foundation was truly a hospital and not an almshouse then it is the oldest English hospital, beating the Angers Hospital founded by Henry II, for which that honour is claimed, by some twenty years or more.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE following subscriptions to the Fund have been received during the week ending March 4th:

	£	s.	d.		£	s.	d.
Messrs. Allen & Hanbury	10	10	0	"Beta"	1	1	0
Mr. G. Rammell Footner	10	0	0	Sir Alfred Pearce Gould	5	0	0
Colonel David Wilkie	1	1	0	Mr. E. Spencer Evans	0	10	0

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

MEDICAL MEN AND TRIBUNALS.

In consequence of the passing of the Military Service Act, 1918, the Local Government Board has issued revised and consolidated Regulations and Instructions to Tribunals, which will come into operation on March 11th, superseding all previous Regulations and Instructions. Regulations 23 and 41, which concern medical men directly, are as follows:

23. In the case of any application concerning a duly qualified medical practitioner, other than an application solely on conscientious grounds, made to a local tribunal, the form of application, together with the documents (if any) in the possession of the tribunal relating to the application, shall be sent forthwith to the Professional Committee for which provision is made by Regulations made under the principal Act. The decision of the tribunal on the application shall be in accordance with the recommendation of the Professional Committee, and a certificate of exemption, if recommended, shall be issued accordingly, provided that—

If application is made on conscientious and also on other grounds, the tribunal shall, after receiving the recommendation of the Professional Committee, hear and determine, if the applicant so desires, the application on conscientious grounds in the same manner as an ordinary application for a certificate of exemption made under these Regulations.

41. In any appeal against a decision made on an application concerning a duly qualified medical practitioner the recommendation of the Professional Committee obtained in accordance with Regulation 23 shall, as regards any grounds other than conscientious grounds, be binding on the Appeal Tribunal.

The provisions in the Regulations as to referring applications by medical practitioners to the Professional Committee apply also to the cases of medical practitioners who are attested.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE *BRITISH MEDICAL JOURNAL*.

All remittances by Post Office Orders must be made payable to the *British Medical Association at the General Post Office, London*. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

Notes ON SURGERY AT SALONICA.

BY
COLONEL SIR T. CRISP ENGLISH, K.C.M.G.,

AND
COLONEL R. E. KELLY, R.A.M.C.,
CONSULTING SURGEONS, BRITISH SALONICA FORCE.

THE campaign of the allied armies in Macedonia has lasted two years, and the present time seems fit for the record of some surgical experiences amongst the British troops in this area.

There are many ways in which this campaign differs considerably from that in France; the extreme cold of winter, the moist heat of summer, the prevalence of malaria and dysentery, difficulties in transport, are all factors which influence the surgical problems.

Malaria, for example, has been most annoying to the surgeon; acute attacks are frequently precipitated by wounds or by any surgical procedure. Moreover, it is found that an acute attack delays or may completely arrest the process of healing; in severe cases the granulating surface

changes in appearance, becoming greyish-brown in colour with a varnish-like brown discharge; under quinine treatment the healthy condition of the wound has usually returned in four or five days. There is the further difficulty that rises of temperature in the case of a wounded man may be due either to malaria or sepsis; the only rational plan is to assume that the raised temperature is due to the latter until the presence of malaria is proved microscopically; even then the temperature may be septic rather than malarial. Chronic malaria has produced little material effect on the healing of wounds, though convalescence is somewhat retarded and the effects of hæmorrhage more felt. The simulation of appendicitis in cases of malaria has been disconcerting; acute pain in the right iliac fossa, onset with vomiting, tenderness, and rigidity may all be present, but a mistake has usually been avoided by the absence of leucocytosis or the discovery of the malaria parasite.

With regard to dysentery, the abdomen has occasionally been opened following a mistaken diagnosis of appendicitis; the caecum and appendix have been purple in colour, very thick and very oedematous, an appearance which reminds one that suture of a dysenteric perforation may be a matter of some difficulty.

The prolonged moist heat of the Macedonian summer also influences the healing of wounds. Its enervating

effects, combined with the prevalence of malaria, have certainly diminished the resistance to infection, and the men wounded in the autumn have not, as a whole, shown the same active recovery as those wounded in the spring.

TRANSPORT.

It need hardly be said that local conditions have caused many difficulties as regards transport of wounded. The tangled mass of hills, scored by innumerable steep-sided douglas, and the scarcity of good roads, necessitated experiments in various forms of transport. It is difficult to say which of these is best, for all have their advantages. The following are in use at the present time:

1. *Travois*.—This consists of a pair of shafts, 15 to 17 ft. long, drawn by a single mule; the patient is slung in a horizontal position. This travois is actually a good deal more comfortable than it looks, and has the advantage that it can be got round a sharp corner. The dis-

advantages are that it may tear or cut telegraph or telephone wires, the ends must be reshod at frequent intervals, and over rough ground it is hard work for one mule.

2. *Mule Litter*.—A single stretcher is slung from horizontal shafts between two mules. This form of transport is expensive both in mules

and men; it is also evident that in very hilly country it is difficult to turn round sharp corners, but it is less tiring than the travois to the mule, and has the further advantage of being easily converted, so that the patient may be carried in the Fowler position.

3. *Cacolet*.—Here a single mule has a double burden. A seat is arranged on either side of the pack-saddle; the distance over which the patient is carried must be short, and obviously the cacolet is suitable only for sitting cases.

Ambulances.

Apart from this, extensive use has been made of the horse ambulance and the motor ambulance; the latter form of transport does all the work between the casualty clearing stations and the base, except so far as railways are available. In good weather the motor ambulances have been able to reach the field

ambulances, and even the advanced dressing stations. The transport over long stretches of country of men wounded in the chest and abdomen was one of the many difficult problems. This applies especially to the abdominal cases, in which speedy transport to an operating station is a matter of urgency. On the whole the travois has worked satisfactorily in these cases, producing a minimum of jolting over rough tracks and roads. In order to attain the Fowler position, two methods are in use—either the canvas of the stretcher is

FIG. 1.—Travois.

FIG. 2.—Mule litter.

lengthened and fixed by iron supports to alter its shape to that of a deck chair, or, simpler still, two triangular wooden wedges are strapped to the stretcher to support the back and thighs.

WOUND TREATMENT.

The general treatment of wounds has followed the evolution seen in other theatres of war. At first the ordinary eusol dressing was most in use. A reaction in favour of the hypertonic saline solution and salt packs then set in; and, finally, Carrel's method of treatment has become the method of choice.

Recent difficulties in evacuation from this area by sea have been all to the advantage of the wounded man, for they have resulted in his receiving continuity of treatment—that is to say, a large number of wounded men have been kept in this country until their wounds have healed, and in many cases treatment has been completed in an orthopaedic dépôt. In this way we have had the opportunity of studying wound treatment in all its phases, and of observing the wounded man from the time of his injury to the final stages of his treatment.

It has always been obvious that a wound should if

standard method in many of the hospitals. Other forms of wound treatment have been in use, but we have not yet seen with them the same consistency of results, the quick sterilization of the wound and its secondary suture, which certainly occurs with Carrel's method. We need not labour the point that good results can only follow the strictest attention to details as laid down by Carrel himself; any half-hearted application of the method or modification has resulted in disappointment. It so happened that the majority of the men wounded during the fighting of last spring were dealt with throughout by this plan of treatment. It was started in the casualty clearing stations, continued on the ambulance trains, and completed at the base. There has been no diffi-

culty in carrying out the treatment during what is commonly called a "rush" after heavy fighting. Arrangements for dealing with large numbers were carefully planned beforehand; the surgeons worked continuously in the theatres, whilst medical officers and sisters, specially trained in the method, carried on the treatment in the wards.

FIG. 3.—Cacolet.

FIG. 4.—Advanced dressing station.

possible be continuously treated by one method, and that if an ideal method could be found it should be made the standard plan of treatment. Carrel's method of treatment appeared to us to approach most closely to the ideal, and during the past eight months it has been used as the

A series of 1,000 consecutive cases, mostly serious, is being published by Major Basil Hughes, D.S.O., R.A.M.C., and show conclusively the excellent results that have been obtained; this series includes 248 cases of fracture of the bones of the extremities and 176 cases of injuries to joints.

A second series of 1,000 consecutive cases is on the point of completion.

As a result of the introduction of Carrel's method, a plan of treatment has evolved which we have recommended as appearing to give the best results. There is nothing new in what is advised; it is simply that the opportunity of co-ordination has occurred. This plan is applicable to those patients who may make a complete recovery in this country within a short time, and also to those who, for one reason or another, stay here for a time before being transported to Malta or England.

1. In the Regimental Aid Posts and the Field Ambulances.

Little is done in the regimental aid posts and field ambulances beyond the general cleaning of the injured area and the application of a dressing; eusol dressings are advised, as they most closely fit in with the subsequent treatment. The finest work that these units can do is the rapid evacuation of the wounded to the clearing station.

2. In the Casualty Clearing Stations.

Carrel's method is commenced in the casualty clearing stations. To repeat: we have recommended this as the standard method of treatment, for it gives all that one wants in early sterilization of the wound with subsequent secondary suture. The method requires surgeons who have learnt it and sisters and orderlies who are trained to it. The initial stage, the operative work on the wound, is of supreme importance; the thoroughness and accuracy with which this is done largely determines the ultimate results.

3. Transport to Base.

On the ambulance train or during other means of transport to the base arrangements are made that the regular sterilization of the wound is not interrupted.

4. At the Base Hospital.

(a) The process of sterilization is continued. The bacteriological condition of the wound is at once investigated; this examination is usually limited to the estimation of the average number of organisms in a field. As soon as the bacteriologist reports the wound ready for suture this is done. Bacteriological control of the progress of the wound is an essential part of the treatment, and the only reliable guide as to its readiness for secondary suture; the clinical appearance of the wound surface has again and again proved deceptive in this respect. The count of the average number of organisms in a field requires no expert knowledge and no elaborate apparatus; it can be done quickly, and is applicable, therefore, to a large number of cases. Recently a number of wounds have been sterilized within the first week; this is mainly due to improvement in technique, and especially to the early performance of

thorough excision—by way of example, two cases of compound fracture of the femur have been sterilized and sutured successfully before the end of the first week.

(b) The orthopaedic side of the question is considered side by side with the actual treatment of the wound. This aspect is sometimes overshadowed by attention being focussed on the healing of the wound; many of the disabilities seen at a later stage are due to neglect of the orthopaedic aspects in the early stages.

FIG. 5.—Compound fracture of femur. Photograph of wound immediately after secondary suture on sixteenth day. Primary union.

5. Orthopaedic Convalescent Dépôt.

The patient is received into this unit as soon as his wounds are soundly healed; he here receives massage, exercises, electricity, and "curative" work, according to the nature of his disability. Further details of this dépôt are given below.

6. Secondary Operations.

Secondary operations are necessary in a certain proportion of cases; these are mainly for the correction of deformities or for the repair of damaged nerves. Under ordinary circumstances the operations are performed after the patient leaves this country; but when the operation will fit the man for duty and when there is delay in his evacuation, the operation is done here.

OTHER METHODS OF WOUND TREATMENT.

Through the courtesy of Dr. C. H. Browning, of the Bland-Sutton Institute of Pathology, samples of proflavine and brilliant green were received and are being used in various forms in a series of cases in one of the general hospitals. The report on this series is not yet completed.

Bismuth-iodoform paste has been employed in a small number of cases, mostly cases with sinuses; a few fresh accidental wounds have also been treated by this paste, but their number is too small to warrant any comparative statement. Our advice has been that this paste should be reserved for those wounds in which sterilization and suture are impossible or have failed.

Primary suture without the use of any special antiseptic has been performed in many cases of wounds of the scalp.

abdomen, articulations, and soft parts; in those cases in which a satisfactory and very early excision of the wound has been possible, primary suture has been a decided success.

WOUNDS OF SPECIAL PARTS.

The following are the main principles that have been adopted for special groups of wounds:

1. Head Injuries.

All gunshot fractures of the skull are operated upon as early as possible and are kept in the unit of operation for at least fourteen days; this unit may be a casualty clearing station or a stationary hospital, according to

FIG. 6.—Group of patients with fractures of humerus treated by Carrel's method.

circumstances. All scalp wounds are excised and explored.

In cases other than those with mere fissures, all loose fragments of bone are removed, and then with freshly sterilized forceps a further half-inch of the surrounding bone is excised; the dura is not opened, if intact; but in cases of penetration the brain for a distance of half an inch is gently explored with the finger and any foreign bodies removed. General opinion is opposed to the extensive use of the horseshoe flap, sliding flaps and primary suture being used in those cases in which the operator feels that he has excised the infected area.

2. Penetrating Wounds of the Chest.

The chief difficulty in these cases has been that in certain areas transport over long distances by road has been necessary. These patients travel very badly, and they have therefore been kept as a rule for at least fourteen days in the casualty clearing stations before commencing their journey by easy stages to the base. On the other hand, when evacuation has been by train, uncomplicated cases are sent down after the third day. Of a series of 105 cases so evacuated, including 72 with definite haemothorax and 23 with pneumothorax, 18 (17 per cent.) subsequently required drainage and 30 simple aspiration.

No operation has been performed for removal of foreign bodies from the lung.

3. Penetrating Abdominal Wounds.

The principle of early operation whenever possible has been in force from the beginning. In certain areas the difficulties in recovering wounded and their rapid evacuation to a clearing station have been considerable. But keen work by the field ambulances has overcome these difficulties, and the majority of the cases reach the clearing station within twelve hours of injury.

Captain E. G. Gauntlett, D.S.O., F.R.C.S., recently reported a series of 28 laparotomies for penetrating wounds with 15 recoveries. In 14 of these cases perforations of the intestine were sutured, and 11 recovered. During the same time at the corresponding base hospital there were admitted 45 cases of penetrating abdominal wounds. Of these 33 had been operated upon in clearing stations and all recovered; 23 involved the small intestine, 5 the large intestine, and 7 the solid viscera. Of the 12 cases operated upon at the base 9 recovered; operation for injury to the small intestine was successful in 7 out of 8 cases.

For wounds of the hepatic and splenic flexures of the large bowel, and wounds of the spleen and diaphragm, we have found that Perthe's incision gives good access; for cases in which a projectile has traversed the upper part of the abdomen from side to side a complete transverse

incision cutting through both recti has allowed perfect exposure; it is sutured with surprising ease, and heals well.

4. Fractures.

Compound fractures are of all injuries the best evidence of the value of Carrel's method. Major Basil Hughes, in his paper already mentioned, brings out two striking points: (1) That in his series of fractured femurs reaching the base, in no case in which Carrel's treatment was started in the casualty clearing station was the limb

lost; (2) that the majority of cases of fractured femur had healed, and were up in walking splints in five to seven weeks after their injuries.

Two illustrations are appended (Figs. 6 and 7) showing patients with fractures of the humerus and femur treated by Carrel's method.

A special department for the treatment of fractured jaws was instituted early this year. All such cases are moved to this department as soon

as they are fit to travel, and are placed under the dual care of a surgeon and a dental surgeon, who have fashioned some beautiful interdental splints.

5. Joints.

It is generally recognized that of joint injuries about half affect the knee-joint; in a total of 176 consecutive cases in one of our base hospitals 85 concerned the knee. Therefore, in considering joint injuries, those of the knee bulk largely both by reason of their frequency and their difficulties.

Opinion as to the best treatment has passed through many phases. Practice in this area has crystallized, and at the present time the following principles are generally accepted:

(a) Rigid fixation in a Thomas splint.

(b) Removal of excess of fluid from the joint; in other words, treatment directed to keeping the tension of the joint at zero; immediate bacteriological examination of the fluid.

(c) Early and complete operation for all cases except those of through-and-through bullet wounds. This, of course, includes a skiagram, the removal of foreign bodies, and the excision, as far as possible, of all contaminated tissues.

(d) The joint cavity is closed whenever possible; the other parts of the wound are also sutured without drainage when an early clean excision has been done; otherwise they are treated by Carrel's method.

In badly infected joints the results have been disappointing in spite of all the recognized forms of treatment, and a large proportion of this group has ended in amputation. We have, however, been surprised to find on occasion that a secondary excision has saved the limb; we recommend, therefore, that an immediate excision be done for cases in which the bones

Fig. 7.—Cases of compound fractures of the femur.

Fig. 8.—Amputation stumps; flaps sutured over Carrel's tubes.

are badly damaged and infection has become established.

6. Burns.

No. 7 paraffin has appeared to us the most efficient form of treatment for burns at the present time. The painlessness of even large dressings and the excellence of the resulting scars are very striking features.

7. Special Infections.

Gas Infection.

There has been a larger amount of gas infection than we had expected from the nature of the country. In the fighting of last autumn it was definitely observed that the number of cases depended directly on the nature of the soil over which fighting took place; there was an immediate jump in the figures as soon as the troops reached villages and cultivated soil. Later the onset of wet weather again increased the proportion of cases of gas infection. In one casualty clearing station statistics were carefully worked out by Captain St. J. D. Buxton, and it was found that gas infection occurred in 3.98 per cent. of all wounds.

Tetanus.

The incidence of tetanus has so far been remarkably

low. As far as we can ascertain there have been only four cases of tetanus amongst the British troops here. Two of these cases died; both had received accidental wounds; in one it was an apparently trivial scratch of the finger and no prophylactic serum was given. One case of anaphylaxis following the injection of anti-tetanic serum has occurred. The patient had had an injection of antitetanic serum in November, 1916; in August, 1917, he received a slight wound of his right leg, and 500 units of serum were given; he vomited after the injection, but soon after was fit to return to his unit. Four hours later he vomited again, became collapsed, and was sent back to the field ambulance. On arrival there he was collapsed and slightly cyanosed; his radial pulse was impalpable, there was considerable oedema of the scrotum and penis, and an urticarial rash on the thighs and chest. With treat-

ment by stimulation, atropine, and adrenalin he recovered in forty-eight hours.

SURGICAL CONVALESCENT DÉPÔT.

A special surgical convalescent dépôt has been in existence during the last four months. Its aim has been to start the important surgical after-treatment in those wounded who for various reasons are unable early to reach the orthopaedic centres at home. Moreover, the simplest form of orthopaedic work carried out at the commencement of convalescence means a great saving of time, and is of inestimable value to the moral and physical well-being of the patient. The principles followed are those which have been laid down by Colonel Sir Robert Jones,

C.B., the Director of Military Orthopaedics.

Each patient on admission has prescribed for him a particular and graduated form of exercise and massage suitable for his disability. These exercises are carried out in a gymnasium, where, under the direct supervision of a medical officer and by means of simple hand-made machines, the disabled muscles and joints are improved.

But, in addition to these methods, great stress is laid on

manual exercises performed in a workshop—the "curative" workshops, as they are called. In them the patient improves his muscles and joints unconsciously; his mind is fixed on the work done rather than on his disability. In the joiners' shop the exercises of sawing, planing, and hammering improve the power of the arm, whilst in using a treadle lathe the exercise of pedalling improves all the muscles and joints of the lower limb.

In another part of the camp

simple sun-dried bricks are made. The acts of digging and mixing the clay, and the bending over the moulds constitute excellent exercises for the arm, back, and thigh muscles. Gardening furnishes similar results.

Finally, under the direction of a metal worker and a saddler, we have started a splint factory. Simple splints in wood and iron are made to measure, and we can now turn out the Thomas's walking calliper splints and a simple

FIG. 9.—Tent for massage.

FIG. 10.—Brick-making.

form of artificial leg. This is fashioned with the upper joint like a Thomas's knee splint and with the lower end simply in the form of a wooden peg.

The few photographs give an idea of the camp and the class of work done there. The success of this camp has been due to the energy and enthusiasm of its commanding officer, Lient. Colonel F. Apthorpe Webb R.A.M.C.(T).

SERBIAN PATIENTS.

Certain of the British hospitals serving in Macedonia have been attached to the Serbian army, and thus we have had an opportunity of studying the surgical aspects of Serbian patients.

Dealing first with non-military diseases, it may be noted that appendicitis is comparatively rare amongst the Serbs; on working out the proportion of cases requiring operation per 1,000 admissions to hospital we find that there have been approximately four times as many cases amongst British troops as amongst Serbs. It is stated that Russians suffer much more frequently from appendicitis than Serbs.

Herniae are common in the Serbs, and a large proportion of inguinal herniae are of the direct type; in one of our hospitals over 30 per cent. of inguinal herniae were direct. Serbian surgeons themselves think that the increased liability to herniae is due to the relative fullness of the abdomen in Serbian children, due to the bulky carbohydrate diet, which weakens the floor of the inguinal canal, and also to the fact that at an early age they carry heavy weights over very hilly country. Surgical tuberculosis has been small in amount, except as regards the epididymis, where it has been observed fairly frequently.

As regards wounds, the Serbs have proved excellent surgical patients: Major K. W. Monsarrat reports that recovery from shock has been rapid, major operations have been well stood, and septic wounds have healed extremely well—for example, in a series of thirty-one amputations through the mid-thigh or at the hip, no case was lost from shock, and only in a few instances was saline infusion necessary. Anaesthetics were taken excellently and pulmonary complications are rare.

Approximately 7 per cent. of shell wounds developed gas infection, and tetanus occurred approximately in one case per 1,000 wounded, with a mortality of 45 per cent.

INTERNATIONAL SURGERY.

The presence of the allied armies in Salonica naturally suggested an interchange of views on matters surgical.

An International Surgical Society was therefore formed under the presidency of M. le Médecin Inspecteur Ruotte, the Director of the French Medical Service in Salonica. Meetings are held once a month, cases being shown and short communications read. In addition, visits have been made to the hospitals of our allies and much of interest

and value has been learnt—for instance, these visits have encouraged the establishment of surgical dressing-rooms in our general hospitals corresponding to the "salles de pansements" found in almost all the hospitals of the other armies. These dressing-rooms deal with all the minor dressings and a large number of walking cases; they economize time and personnel and allow attention in the wards to be concentrated on the treatment of the serious cases.

Surgery at Salonica has been made easy by the ever-ready help and encouragement of those who have directed the medical service there; to them our most grateful thanks are due. For the photographs which accompany this paper we would express our gratitude to Lient-Colonel E. J. Williams, D.S.O., C.A.M.C., and to the Survey Department, Royal Engineers.

THE Medical Research Committee has issued a report upon 2,360 enteritis "convalescents" received at Liverpool from various expeditionary forces (Special Report Series, No. 7, V). The investigations were both bacteriological and protozoological, and formed part of the combined studies arranged by the Committee in 1915 at the chief centres in the country at which military patients and convalescents were being received with the diagnosis of dysentery or "enteric" from the Mediterranean and other areas. In the first part of the report Professor Glynn and his colleagues describe the technical methods used, with special reference to agglutination tests. A very high estimate was formed of the value of the typhoid and paratyphoid emulsions of the Oxford Standards Laboratory, and the technique suggested by Dreyer for their use is considered to be the "best method for routine work in the army," giving also the additional

advantage of convenient standardization. The Oxford dysentery emulsions were not found so eminently satisfactory, but it is thought that recent improvements in them will give better results. The second part deals with specific bacteriological observations, the results of which are correlated as closely as possible with those of other workers elsewhere. The third part gives the main results of protozoological examinations, under the direction of Professor J. W. W. Stephens, made in parallel series with those of the bacteriologists working in the same material.

INFECTED WOUNDS OF THE KNEE-JOINT.

BY

K. W. MONSARRAT, MAJOR R.A.M.C.(T.F.),

SALONICA ARMY.

THE total number of cases which are reviewed here is 38. All were either Serbs, Russians, or Bulgars, admitted to hospital during the period August, 1916, to August, 1917. In all cases the condition was an infected wound involving the joint. Several were in the charge of my colleague, Captain L. D. Woods, R.A.M.C., surgical specialist in the hospital, to whom I wish to make my acknowledgements.

Of the total, 13 were admitted either four days or later after being wounded, 25 within the first four days.

The Influence on Results of Early Surgical Treatment.

Of the 25 cases treated within four days of the receipt of the wound—

18 recovered without amputation.
4 recovered after amputation.
3 died.

This shows a recovery of 72 per cent. without amputation. Of the 13 admitted on the fifth day or later—

4 recovered without amputation.
3 recovered after amputation.
6 died.

This shows a recovery of 30 per cent. without amputation.

The following table gives these figures, but distinguishes further between the cases with bone lesion or retained foreign body, and those of infected joint wound without these complications.

A. With Bone Lesion or Retained Foreign Body.

Early admissions (within four days):

Recovered	14
Amputation	2
Death	1

Late admissions:

Recovered	4
Amputation	2
Death	5

B. Without Bone Lesion or Retained Foreign Body.

Early admissions:

Recovered	4
Amputation	2
Death	2*

Late admissions:

Amputation	1
Death	1†

* One case multiple wounds, death following amputation at shoulder.

† Gas gangrene of whole limb, the wound being of knee-joint.

Another point of importance showing the influence of early treatment is the recovery of function in the joint.

Of the 22 cases surviving without amputation 13 left hospital with recovery of function in the joint—that is to say, with a greater or less range of voluntary movement. I am unable to say how many of these eventually recovered with a "useful" joint, but the majority were at any rate promising. The point is of chief value in showing that the joint changes did not in these cases go on to complete destruction.

Of these 13 cases—

3 were admitted the day following the wound.
4 were admitted on the second day following the wound.
5 were admitted on the third day following the wound.
1 was admitted on the seventh day following the wound.

That it was by no means always the least complicated case which made a good functional recovery is shown by the following two histories:

Case 25.

No. 4483. Admitted December 1st, 1916. Wounded November 27th. The projectile passed through the knee-joint and fractured the femur. The joint was infected.

Operation.—Wounds excised, fragments of femur removed. Transverse incision above patella into joint. Joint washed out with saline. No drainage, no sutures.

December 7th, 1916. Wounds clean.
January 25th, 1917. Wounds healed; good movement in joint.
March 5th. Discharged to duty. Pain less and almost normal range of movement.

Case 35.

No. 7152. Wounded May 15th, 1917. Admitted May 18th, 1917. Entrance wound above outer upper quadrant of patella; wound traverses femur, comminuting the junction of shaft and

condyles; exit wound below adductor tubercle. Temperature on admission 100.4°.

Operation.—Wounds excised, loose fragments of femur removed. Joint full of pus and blood. Transverse incision above patella into joint. No drainage material used into joint; tube passed through special incision down to trigone of femur at site of fracture. No sutures.

May 24th. Pyrexia. General condition good. Wounds healthy.

May 28th. Inflammatory swelling of joint structures subsided.

July 12th. Good movement in knee-joint. Lower end of upper fragment of femur is displaced somewhat backwards.

These groups of figures indicate the urgency of operative treatment in infected knee-joint wounds, and the fair results which may be expected in cases so treated.

I am unable to give the bacteriology of the majority of the infections. I am aware that some surgeons attach much importance to this as a guide to treatment; for my own part I do not, for two reasons: firstly, that I have seen knee-joints left unopened because they were reported as staphylococcal infections, but went completely to the bad and ended in amputation; secondly, because there is no danger in opening a knee-joint if certain things be done and others left undone. Bacteriology and the cytology of the effusion are of importance in prognosis, but that they provide a reliable guide to treatment is contrary to my experience.

Operative Treatment of Early Infections.

Punctured penetrating wounds of the joint with effusion are not included in this communication. All that is required in such cases is fixation. This should be both absolute and prolonged. In early infections—that is to say, in cases in which the infection is not so established as to have disorganized the joint—the details of operative treatment are as follows:

(a) Excision of the wound, or wound, including the capsular and synovial membrane wounds.

(b) Evacuation of effusion.

(c) Removal of foreign bodies and of detached bone fragments.

(d) Transverse incision into the joint a fingerbreadth above the patella 4 in. in length.

(e) Either (and usually) no sutures or catgut suture of the excised wound passing through synovial membrane only. No drainage material passed into the joint.

(f) Fixation on splint, with fixed extension and elevation of the limb to an angle of 45 degrees at the hip-joint.

It is usually necessary to maintain the patency of the transverse incision into the joint by passing a pair of dressing forceps at the daily dressing for three or four days. The results shown in the cases of which details are given here appear to me to demonstrate the value of this method of operative treatment in cases in which infection is not advanced.

When the joint wound is complicated by fracture the question of a *primary* resection of the joint may be entertained if the stability of the joint is otherwise doubtful. This operation has probably a very limited utility; it is only likely to be successful in early cases in which the infection is not acute. It was not carried out in any of the cases reported here except Case 16, in which a resection was done elsewhere before admission.

Indications for Amputation.

When cases submitted to arthrotomy continue to exhibit signs of active infection on the days following operation a secondary amputation should be done; no lesser procedure is likely to be successful. Delay in amputating in such cases beyond the third day after arthrotomy is likely to be dangerous.

Case 34.

No. 7090. Admitted May 16th, 1917. Wounded May 14th. Grenade wound. Entrance to inner side of ligamentum patellae; joint distended. No exit.

Operation.—Foreign body removed from head of tibia; wounds excised; transverse incision above the patella. No drainage.

May 19th. Joint condition unsatisfactory. Three Carrel's tubes inserted, two down into lateral joint pockets, one down to wound in head of tibia.

May 24th. General and local condition worse; temperature last night 101°, pulse 120; this morning temperature 101.6°, pulse 116.

May 25th. Death.

Amputation was delayed too long in this case; during the last two days it was judged inadvisable owing to the general condition.

A secondary formal resection has been advocated in some of these cases of established infection as an alternative to amputation. It is certainly advisable to confine it to cases in which there is definite reason to believe that the infection is of a subacute type. The objections are:

- (a) The danger of uncontrollable septic osteitis.
- (b) The probable instability of the resulting "joint."

No evidence has yet been produced to show that if resection is done in these cases of established infection and the bone surfaces are separated a stable limb is likely to result.

Amputation is advisable if infection of the joint is complicated by a serious bone injury, if, for example, the condyles are shattered or a fracture extends from joint into shaft and infection is well established. Amputation is further indicated if the joint wound is complicated by injury to the femoral or popliteal artery or by section of internal or external popliteal nerves.

In the treatment of patients transferred from other units and admitted in the subacute stage, in which the joint is more or less infiltrated with septic granulation tissue and there are various operation wounds more or less providing drainage, in my opinion the choice of procedure lies between:

(a) Leaving them alone carefully splinted and only operating if some secondary collection in the thigh or leg presents itself.

(b) Amputation. This should be chosen when signs of general infection and septic intoxication persist; when secondary collections or tracks are present in the popliteal space; when it is obvious from the extent of the bone destruction that a weight-carrying limb cannot be anticipated. A large proportion of the cases with posterior collections and tracks end in secondary haemorrhage. Bone loss, which will leave crippling deformity and joint disorganization, which has resulted in falling back of the tibia from the femoral condyles, will always lead to a decision to amputate.

The cases fall into two groups—that belonging to the autumn and winter of 1916 and that belonging to the months of May, June, and July, 1917. In the earlier group the method of arthrotomy advocated above was not employed as routine; in most of them drainage tubes were placed in the joint, and in other respects the operative procedure differed from that adopted in the later group. The results obtained in the nine cases belonging to the later group were much superior to those obtained in the earlier, and this fact in my opinion is due to—

1. Operation at the earliest possible time.
2. Early removal of foreign bodies and loose bone fragments.
3. Careful wound excision.
4. Omission of drainage tubes and sutures.
5. Provision of drainage by transverse incision above the patella combined with elevation of the limb.
6. Complete fixation, with fixed extension.

Case 1.—C. 5. Admitted August 22nd, 1916. Shell wound of left knee. Removal of shell fragment; wound excision; arthrotomy. Recovery.

Case 2.—F. 8. Admitted August 23rd, 1916. Shell wound of right knee. Removal of foreign body; wound excision; arthrotomy. Recovery.

Case 3.—B. 7. Admitted August 24th, 1916. Bullet wound of left knee. Removal of bullet; wound excision; arthrotomy. Recovery.

Case 4.—B. 5, Bulgar. Admitted August 16th, 1916. Shell wound of right knee; fracture of femoral condyles; septic osteitis established. Arthrotomy; incisions. Death August 27th.

Case 5.—534. Admitted August 21st, 1916. Gunshot wound of left knee. Subacute infection. No operation on admission. Arthrotomy August 29th. Transferred convalescent October 30th.

Case 6.—1218. Admitted August 27th, 1916. Gunshot wound of left knee; fractured femur. Amputation through thigh September 1st. Death from septicaemia October 23rd.

Case 7.—2032. Admitted September 14th, 1916; wounded September 12th. Gunshot wound of right knee. Shell fragment in femur, with fracture of external condyle into joint; infected. Foreign body removed; arthrotomy; no drainage; no sutures. February 19th, 1917: Function of joint good; only slight restriction of extension. Transferred February 26th.

Case 8.—2007. Admitted September 14th, 1916. Wounded September 12th. Gunshot wound of left knee; infected. Removal of foreign body; arthrotomy. November 29th: Transferred; healed; fair movement in joint.

Case 9.—2048. Admitted September 14th, 1916. Removal of foreign body; arthrotomy. Further incisions for secondary collections September 24th and 29th. Transferred November 22nd. Convalescent; ankylosis.

Case 10.—1434. Admitted August 27th, 1916. Gunshot wound of right knee. Compound fracture of femur; infected. Wound excision, arthrotomy the same day. Incisions for secondary collections September 29th and November 6th. Amputation through the mid-thigh November 24th. Transferred February 12th, 1917.

Case 11.—1180. Admitted August 27th, 1916. Gunshot wound of left knee. Arthrotomy August 29th. Progress unsatisfactory. Death from septicaemia September 25th.

Case 12.—2250. Admitted September 20th, 1916; wounded September 17th. Infected wound of right knee; fractured patella. Wounds excised on day of admission. No drainage. Gradual subsidence. Transferred January 24th, 1917. Healed; ankylosis.

Case 13.—2253. Admitted September 20th, 1916. Gunshot wound of right knee; fractured femur. Wound excision; arthrotomy. Further incision October 23rd. Amputation November 13th. Transferred February 12th, 1917.

Case 14.—2566. Admitted September 30th, 1916; wounded September 29th. Gunshot wound of left knee; infected. Internal condyle comminuted; fractured patella. Bomb fragment passed through joint. Arthrotomy; wounds excised. January 27th, 1917. About twenty degrees of movement in joint; marked genu varum. Wounds healed. February 15th, supracondylar osteotomy to correct deformity.

Case 15.—2654. Admitted October 2nd, 1916. Gunshot wound of right knee; infected. Operated on October 6th. Removal of foreign body; arthrotomy. Subsequent operations, October 13th, 18th, and 20th. Death October 23rd from septicaemia.

Case 16.—3077. Admitted October 14th, 1916; wounded October 4th. Gunshot wound of left knee, infected, with fracture of lower end of femur. Before admission had "atypical resection" of joint; condyles removed. Admitted four days after this operation. Profound infection. Secondary haemorrhage from popliteal artery December 20th; amputation through upper third of thigh same day. Transferred March 2nd, 1917.

Case 17.—3532. Admitted October 26th, 1916. Gunshot wound of right knee; infected; subacute infection. Arthrotomy. Gradual subsidence. Recovery.

Case 18.—3566. Admitted October 30th, 1916. Gunshot wound of left knee. Removal of foreign body November 1st, and wound excision; arthrotomy. Recovery. Transferred November 20th.

Case 19.—3946. Admitted November 13th, 1916. Gunshot wound of right knee; infected. Knee-joint opened and drained. Continued infection. Amputation through mid-thigh December 19th. Transferred February 12th, 1917.

Case 20.—3950. Admitted November 13th, 1916. Gunshot wound of right knee, arm, and hand. Removal of foreign body and drainage November 18th. Incisions for drainage of secondary collections December 26th. Death from septicaemia pneumonia January 9th, 1917.

Case 21.—4341, Bulgar. Admitted November 25th, 1916. Gunshot wound of right knee; fractured patella; frostbite both feet. Operation November 26th. Removal of patella, lateral and posterior incisions into knee-joint. Amputation through mid-thigh December 4th. Death December 15th.

Case 22.—4324. Admitted November 23rd, 1916. Gunshot wound of right knee by shell fragment. Entrance outer side of popliteal space; exit over inner tuberosity of tibia; tibial tuberosity smashed. No foreign body present; subacute infection. No operation on admission. January 13th, 1917, slipped and injured knee; effusion, pain, pyrexia. January 17th, continued pyrexia, 102.4°. Knee opened above patella, washed out, and closed; sero-purulent fluid. January 25th, same operation repeated. Transferred convalescent March 5th.

Case 23.—4345. Admitted November 25th, 1916. Gunshot wound of right knee and left upper arm. Amputation at shoulder-joint. November 26th, arthrotomy, right knee. Death two days later from shock.

Case 24.—4347, Bulgar. Admitted November 25th, 1916. Admitted moribund; gas gangrene spreading from gunshot wound of left knee. Death the following day.

Case 25.—See text above.

Case 26.—4590. Admitted December 5th, 1916; wounded December 3rd. Gunshot wound of right knee; infected. December 6th, wounds excised; foreign body removed; joint washed out with saline; no drainage. March 5th, 1917, fair movement in knee-joint; wounds healed. Transferred.

Case 27.—4691. Admitted December 9th, 1916. Gunshot wound of right knee; infected. Entrance wound above patella; exit on outer lateral aspect. December 11th, joint opened by transverse incision above patella. December 16th, two lateral incisions added. December 29th, collection under

quadriceps opened. January 20th, 1917, amputation through mid-thigh. Transferred April 4th.

Case 23.—4778. Admitted December 13th, 1916. Gunshot wound of left knee; infected. Fractured patella. Wounds excised on admission. December 20th, lateral incision into joint; washed out with saline; no drainage. January 26th, 1917, wounds healthy, granulating. February 7th, collection in calf tracked down from popliteal space under outer head of gastrocnemius; opened by three transverse incisions. April 7th, healed; slight voluntary movement. Transferred.

Case 29.—168 (O). Admitted November 20th, 1916. Gunshot wound of right knee; infected. Amputation through mid-thigh the following day. Recovery.

Case 30.—6919. Admitted May 10th, 1917; wounded the same day. Gunshot wound of left knee. Joint distended; wounds lacerated, through-and-through; entrance outer side ligamentum patellae; exit behind semimembranosus tendon. May 11th, wounds excised; arthrotomy; turbid fluid. Transverse incision above patella. May 24th, apyrexia; local condition satisfactory. June 8th, healed; still on splint. July 1st, discharged; fair and increasing movement in joint.

Case 31.—7072. Admitted May 14th, 1917; wounded May 11th. Through-and-through wound from outside; infected. Operation on day of admission. Wounds excised; loose fragments of head of tibia removed; transverse incision above patella; no drainage tubes, no sutures. May 18th, local and general condition satisfactory. May 24th, apyrexia; wounds clean. June 9th, wounds healing; joint quite healthy. August 6th, good range of voluntary movement in joint.

Case 32.—7080. Admitted May 14th, 1917; wounded the previous day. Single wound to outer side of patella; joint distended. Operation May 15th. Wound excised; foreign body removed; arthrotomy. Joint full of turbid blood; bacteriological report, staphylococcal infection. May 24th, general and local condition good; wounds healing. June 8th, normal progress. July 22nd, fair voluntary movement in joint.

Case 33.—6953. Admitted May 12th, 1917; wounded May 10th. Bullet wound from distance of 10 metres. Fractured tibia and fibula; septic. Arthrotomy; removal of bone fragments; three Carrel's tubes. May 16th, septic condition persists. May 24th, some improvement, local and general. June 4th, Amputation through mid-thigh. Recovery.

Case 34.—See text above.

Case 35.—See text above.

Case 36.—7403. Admitted May 26th, 1917; wounded May 23rd. Grenade wounds both thighs. Three wounds on outer side of right thigh, one involving knee-joint. Operation May 27th. Wounds excised; knee wound excised to joint; fragments of fractured patella removed; no foreign body found. Transverse incision above patella; no drainage, no sutures. June 8th, knee-joint satisfactory; some discharge from wound on outer side of ligamentum patellae. No oedema of joint structures. August 10th, wounds healed; slight voluntary movement in knee-joint.

Case 37.—7617. Admitted June 7th, 1917; wounded June 5th. Grenade wound of left knee. Entrance on inner side, fracturing anterior aspect of femoral articular surface. There is also simple fracture of middle of shaft of femur, without direct relation to gunshot wound. Transfer notes say: "Arthritis purulenta, phlegmon incipiens; arthrotomia facta." Tube and gauze in the joint on admission. June 8th, tube and gauze removed; transverse incision above patella; joint "very septic." No drains of any sort inserted. The limb fixed on a Wallace-Maybury splint and elevated. June 25th, irregular pyrexia until 20th, since then apyrexia; wounds healthy. August 10th, patient goes about on crutches. Wounds healed; slight movement in knee-joint. About a quarter of an inch shortening of limb.

Case 38.—9030. Admitted July 22nd, 1917; wounded July 20th. Single contused and septic gunshot wound on outer side of right knee; skiagram shows foreign body (portion of shell) above patella and in front of femur. Patella fractured. Temperature 101°. July 23rd, operation. Wound excised, including wound of capsule and synovial membrane. Loose fragments of patella removed. Transverse incision above the patella; foreign body removed; joint full of turbid blood. Suture of excised wound in synovial membrane with catgut. No other sutures. August 4th, temperature fell to normal two days after operation and has remained so. Wounds now healing; no oedema of joint structures.

THE (American) National Association for the Prevention of Tuberculosis, in co-operation with the surgeon-general of the army, the Y.M.C.A., and other agencies, has drawn up a plan for a military anti-tuberculosis campaign. The name of every man discharged from the army on account of tuberculosis will be sent to the various State organizations and health boards so that the case may be followed up. The association is also co-operating with the surgeon-general to help the Government in providing the necessary sanatoriums. The educational part of the programme includes the supply of a number of stock lectures with lantern slides, and a number of special tuberculosis exhibits with moving picture films will be sent to the camps.

THE PREVENTION OF THE SPREAD OF EPIDEMIC DISEASE AT SCHOOLS.

BY

H. MORLEY FLETCHER, M.D., F.R.C.P.,

MAJOR R.A.M.C.(T.),

PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

EPIDEMIC diseases at schools, especially measles, are a constant source of anxiety to all masters and doctors. In the early part of last year epidemic disease assumed grave proportions, and was of unusually severe type at many of the schools, even causing serious loss of life.

Much care and thought has been spent on combating these outbreaks, but, in my opinion, too little attention has been paid in recent years to the study of their prevention. In any epidemic it is those who have been exposed to the infection who should be dealt with, and any measure which can limit an outbreak in a school by checking the development of the disease in such "contacts" and probable "contacts" deserves the closest consideration.

In 1915 Lieut.-Colonel M. Gordon was appointed to organize a special department to deal with the investigation and treatment of cerebro-spinal meningitis. One of the most serious problems presented was the treatment of carriers, investigations having shown that a considerable number of soldiers, though not suffering from the disease at the time, had the meningococcus, often in large numbers, in the naso-pharynx. Many instances occurred in which such apparently healthy individuals conveyed the disease to others presumably possessed of less powers of resistance. To disinfect or to render harmless these carriers Colonel Gordon and his staff, after much experimental work, introduced a steam spraying apparatus designed by Major Hine, the disinfecting agent used being chloramine-T.¹ The method was fully described in his paper in the BRITISH MEDICAL JOURNAL, November 18th, 1916; since then the apparatus has been greatly improved and enlarged. Chloramine-T was superseded by a zinc sulphate solution, as this was found to be at least as efficacious and better tolerated by most individuals. In addition to the inhalation of the medicated steam spray, Colonel Gordon introduced a system of nasal douching and of gargling with potassium permanganate solution in normal saline, which was both simple and effective. The solution is poured into the palm of the hand and snuffed up one nostril, the other being closed with the finger, and the process repeated with the other nostril. The fluid which has passed down the naso-pharynx is spat out. The patient is then instructed to gargle thoroughly with a fresh quantity of the fluid.

Although originally devised for the treatment of carriers of the meningococcus, it was obvious that the spraying method might be useful in the prevention of other infectious fevers, and, so far as I know, its first application was on a transport ship in which measles had broken out and a severe epidemic appeared to be inevitable. The results of the treatment were most striking—no further cases occurred.

It occurred to me that it would be important to apply the same methods to the prevention of epidemics of various infectious fevers in schools and elsewhere. The first opportunity which I had of trying the efficacy of the nasal douching was at the 1st London General Hospital. In a large and overcrowded ward of forty-six beds a soldier was admitted on December 5th, 1917, with fever and bronchitis. Three days later he developed typical measles. All the patients on that floor (about 100) were put in quarantine, and orders were given that all patients and nurses on that floor were to nasal douche and gargle twice daily (a 1 in 4,000 solution of potassium permanganate in normal saline was used). On the fourteenth day one fresh case occurred in a V.A.D. nurse, who, as it turned out, had been the only person on the floor who had not carried out the orders. No subsequent cases arose. Dr. Mouncey Atkinson, the resident medical officer, who very ably superintended the carrying out of these measures, has reported to me that in every case which has occurred in the hospital since then these precautions have proved efficacious. No contacts have developed the disease with the exception mentioned above.

Apparatus for steam spraying is being installed at various naval and military centres and at Osborne and

Dartmouth Naval Colleges. One has been fitted up at St. Bartholomew's Hospital under Professor Andrewes's supervision, and has already proved useful in the prevention of the spread of epidemic disease amongst the resident staff and nurses.

With the approval of the Medical Research Committee and with the kind assistance of Major Hine, I have been able to fit up at one of the public schools an experimental boiler for steam spraying; with this a 1½ per cent. zinc sulphate solution is employed. At the same time a simple routine of nasal douching and gargling is being carried out with 1 in 4,000 potassium permanganate. A nasal glass tube or irrigator is used instead of the snuffing method mentioned above. With the co-operation of the head master and the assistance of the school doctor and of the matron we are making observations which are already highly gratifying. Although it is too early to draw definite conclusions as to the value of these measures, I may say that already cases of measles, chicken-pox, and rubella have occurred during this term, and in no instance has any secondary case developed. I hope to be able to publish the results of our work at an early date.

My object in drawing attention to these methods of preventive treatment is that a great amount of public and private money is wasted by the frequent outbreaks of epidemic disease in schools, in addition to the loss of time to the boys through the dislocation of their work. In institutions where it is found to be impracticable at present to install a steam spraying apparatus I would urge the trial of nasal douching and gargling, which there is reason to believe will prove of great utility.

I wish to acknowledge my indebtedness for help given by the Medical Research Committee, and Lieut.-Colonel Gordon and Major Hine.

MEDICAL, SURGICAL, OBSTETRICAL.

QUININE IN THE TREATMENT OF ANAL FISSURE.

In the present circumstances it seems more than ever desirable to record, for the use of other practitioners, any slight advance in treatment which will save time and trouble to patient and doctor.

A typical case of anal fissure came under my care and refused operative treatment. There were tuberculous glands in the neck, a pile, and a fissure a quarter of an inch deep extending upwards from the base of the pile for more than an inch and a half. After trying the usual palliative remedies without result, and remembering the granulating power of quinine, I packed the fissure with quinine hydrochloride (about five grains) after swabbing with cocaine solution. This treatment was repeated on each of three days. In twenty-four hours the surface showed well-marked granulations, and the patient's symptoms were much relieved. She slept all night after having had pain, severe enough to prevent continuous sleep, for ten days.

After the third day that part of the fissure within reach was looking healthy, but the patient complained of pain higher up. I therefore prescribed enule cocaine gr. ½, to be followed in a quarter of an hour by enule quinine sulphate gr. 5. These were used on four days, and by that time the fissure was quite healed and all pain and symptoms had disappeared; there has been no recurrence.

The extension of this method of treatment to bullet wound and other sinuses suggests itself.

Oxford.

HELEN G. LEYTON, M.D.

A CASE OF MAGGOTS IN THE NOSE.

In October, 1916, while acting as nose, throat, and ear specialist to a general hospital in India, the following case came under my care:

A. B., aged 55, complained of a headache, ascribed to a debauch on the previous evening. The next day the headache continued; he complained of pain in the nose and left ear and had an attack of epistaxis, more copious from the left than the right nostril. During the day he had several other attacks and

the headache became much more severe. When admitted to hospital both sides of the nose were full of recent blood clot, which, it was apparent, did not originate from any bleeding vessel in Kiesselbach's area on either side. There was no history of previous nasal trouble. The left lobe of the liver was somewhat enlarged. The patient was kept quiet in bed and given calcium lactate, and the next morning found about thirty maggots on his pillow which had evidently fallen or been sneezed out of his nose during the night. The nostrils were thoroughly painted inside with liquid vaseline several times a day, which has the effect of occluding the respiratory organs of the insects. During that day and the next more larvae came away, and the bleeding entirely stopped. In all, some fifty to sixty larvae were counted, and the pathologist to the hospital was able to hatch flies from them in artificial media. The patient slowly recovered his strength, and three weeks later the headache had disappeared, and he was walking about.

The nose presented an extraordinary appearance. The greater part of the bony septum was destroyed, as also the turbinate bones on either side. It was extremely difficult, even with the most scrupulous care, to keep the nostrils free from foul-smelling crusts; well-marked atrophic rhinitis was present and persisted. There were, however, neither signs nor symptoms of sinus complications, and the patient was discharged from hospital for light duty at the end of six weeks.

The difficulty of diagnosis and the success of thorough early treatment appear to me to be the outstanding features of this case. It is probable that the insect obtained access to the nostrils and deposited its ova during a period when the man was lying outside in the open air intoxicated. Though most cases of this nature seem to occur in patients who suffer from some pre-existing pathological condition of the nose such as syphilis or some form of atrophic rhinitis, there was no previous history of either condition in this instance. Judging from a certain number of recorded fatal cases in which there appears to have been an invasion of the cranial cavity through the cribriform plate of the ethmoid, followed by intracranial sequelae, or from those which have ended fatally in septicaemia, this patient seems to have had rather a fortunate escape than otherwise, in spite of the havoc wrought in his nose by the maggots.

DAVID RANKEN, M.S.Lond., B.S.Durh.,
F.R.C.S.Eng., Captain R.A.M.C.

Reports of Societies.

SELECTION OF CANDIDATES FOR THE AIR SERVICE.

At a meeting of the Medical Society of London on March 11th, the President, Sir STCLAIR THOMSON, being in the chair, Surgeon H. GRAEME ANDERSON, R.N., attached R.N.A.S., read a paper on the selection of candidates for the air service. He suggested that for eliminating the unfit a special flying school should be instituted where border-line pupils could be instructed in flying under patient and sympathetic instructors, and with a medical officer specially interested in aviation carefully recording the results. In selecting candidates for the air service a sound constitution free from organic disease was looked for, and a fairly strong physique, in order to withstand altitude effects, such as cold, fatigue, and diminished oxygen. Normal hearing and good muscle and equilibrium sense were essential, and good eyesight was of the greatest importance. Next to vision the question of temperament was most important. The ideal aviator must have good judgement, be courageous, and not upset by fear, although conscious of the perils of his work. He must be cool in emergencies, able to make careful and quick decisions, and act accordingly. He must be ever alert, as mental sluggishness in flying spelt disaster. An aptitude for flying was found most commonly amongst those used to playing games and leading an outdoor life. Racing motorists had not made the best pilots. Candidates should be made to undergo a surgical examination, a medical examination, and a special sense examination, preferably carried out by experts in each line, and the final selection made on the total results by a medical selection committee.

Surgical Examination.

The age should be between 18 and 30 years, 24 years being about the best, though much depended upon the physiological age. Height did not matter much, but the candidate should not be under 5 ft. 2 in. As to weight, the lighter the candidate the better, but this did not

count so much as formerly. Colour, physique, attitude, and tone of muscles should be noted, especially the abdominal muscles. A previous history of wounds and injuries had to be considered carefully, especially of injury to the head followed by prolonged unconsciousness, and fairly recent in origin. Any evidence of epilepsy, vertigo, migraine, persistent headaches, lack of concentration, and easily induced fatigue, should disqualify. Loss of cranial vault need not disqualify. Limb injuries might disqualify, depending upon the amount of disablement and deformity. Men with gunshot wounds of the thorax need not be rejected unless they failed to pass the altitude tests as devised by Major Flack. The significance of disabilities of the extremities depended upon the extent to which these interfered with the power to work the controls or use the machine gun. Most movements in controlling an aeroplane were performed below the level of the shoulder. It was more important that the candidate should have both arms intact than both legs. If an amputation were below the knee an artificial leg and foot would act quite well on the rudder bar. If the amputation were above the knee the artificial leg was dispensed with, and the normal foot was strapped to the rudder bar, the latter being pressed forward or drawn back in the aeroplane's control by the sound leg. Old infantile paralysis cases should be rejected owing to the danger of trophic lesions being produced by the cold altitudes. Candidates suffering from venereal diseases should be rejected temporarily.

The Medical Examination.

This included inquiry into previous occupation, habits, and mode of life, previous health, and family history. Inquiry into the candidate's habits should especially refer to tobacco and alcohol. Excess in smoking led to palpitation, shortness of breath, and in some cases double vision, and these dangers should be explained to candidates. Amongst pupils at a flying school alcohol should be strictly forbidden, and they should be warned of its danger to flying. There seemed to be little doubt that the action of alcohol was accentuated in the air. Recent temporary illnesses such as influenza and tonsillitis might hinder a candidate from passing the tests, and there should be a further examination later on. A history of recent or imperfectly treated syphilis should be a cause for rejection, as also should be a history of malaria with recent attacks. The cold experienced in flying undoubtedly precipitated malarial attacks. If such candidates were allowed to fly at all it should be in warm climates. A history of epilepsy or *petit mal* should disqualify. Candidates with a history of neurasthenia, nervous breakdown, or mental depression rarely did well in aviation. Those with a history of shell-shock soon developed some form of aero-neurosis. Such histories should be estimated from the standpoint of date, duration, original severity, and the lapse of time with freedom from symptoms. A candidate need not be rejected on account of seasickness or train-sickness, except for balloon work. Cases of real air-sickness due to the rolling and pitching of the aeroplane in bumpy or gusty weather were comparatively rare.

The family history, especially with regard to diseases of the nervous system, might shed some light on the type of soil with which one had to deal, especially in relation to the strain of war flying. If albumin or sugar were present in the urine the candidate should be rejected. In the digestive system note should be taken of the tone of the abdominal muscles. If poor and there was some dilatation of the stomach—danger signals that splanchnic flooding and fainting in the air might occur—candidates should be sent back for physical training, and, if passed for flying, should be advised to wear an abdominal belt.

In the circulatory system any organic disease of the heart should cause rejection. Equally important was any evidence of instability of the vasomotor system. Raynaud's disease should disqualify. Candidates showing coldness of the extremities, with signs of defective peripheral circulation and a history of easily induced chilblains, should not be allowed to fly at great heights, but rather be graded for low flying duties. He would place such candidates in the special flying school; many of the cases might be due to recent temporary illness, and many could be improved by physical training. He did not attach much importance to the pulse-rate.

With regard to the respiratory system, any evidence of active tuberculosis, emphysema, bronchitis or pleurisy disqualified for air work. In war time an aviator might have to fly at any height up to about 21,000 feet; at this altitude the available oxygen was reduced by one half, and consequently the respiratory rate was increased. Many aviators felt quite undisturbed; some had respiratory distress, fatigue, headache, faintness and blurring of vision, and epistaxis, and had to descend; whilst some actually fainted in the air. The problem why some were affected and some were not at great altitudes had been investigated by Major Flack, R.A.M.C. In his breath-holding test the candidate, seated, was told to expire once as fully as possible, and then to inspire fully, and hold his breath as long as possible. Most good pilots were able to hold their breath for 60 seconds or more—45 seconds was the minimum for the test. During the breath-holding there was a depletion of the alveolar oxygen, and the candidate was submitted to a gradually rarefying atmosphere, as in ascending to a high altitude. This test had been confirmed by other tests, and it had been proved that pilots who suffered at altitudes could not hold the breath as long as those who were unaffected.

In the nervous system any organic disease of brain or spinal cord disqualified a candidate. Mentality and temperament should be studied carefully, and knee-jerks recorded. An exaggerated knee-jerk might indicate an unstable nervous system. Candidates were tested for tremor by being made to stand with eyes shut, tongue out, arms extended, and fingers slightly flexed and spread apart. Inquiry should be made into the usual amount of sleep obtained, and whether disturbed or not. Any signs of restlessness should be noted, as they might point to an unstable nervous system.

Special Sense Examination.

The aviator should have unaided normal vision in both eyes, and in each eye separately. Candidates should be examined for concealed hypermetropia, which had been found in some cases to be the cause of making bad landings. A candidate reading $\frac{5}{6}$ with each eye with a +2 D lens should be rejected. Candidates with heterophoria, or concealed squint, should be tested by the red and green light test, and watched by the aerodrome doctor. Pilots and observers should have perfect colour vision, which was of importance in picking out the colour or marking of hostile machines, in recognizing signal lights, and judging the nature of landing grounds. Testing for night blindness was only of importance in grading pilots for night bombing.

In the examination of throat, nose and ear the previous history should be noted with regard to pyorrhoea, recurring sore throat, earache, deafness, or discharge from the ears. Teeth and gums should be examined, since pupils must commence flying dentally clean. Most aviators kept the mouth slightly open, and any minor degree of oral sepsis flared up owing to the cold or rush of air experienced in flying. Septic tonsils should be enucleated. The nose should be examined to estimate the amount of clear airway. Many pilots with septal deviation and enlarged turbinates returned suffering from headaches induced in the air. Candidates with adenoids, nasal polypus, or infected sinuses should be rejected until treatment had been carried out. Hearing should be normal, and each ear should be tested by forced whisper at a distance of 20 feet. Candidates with chronic suppurative disease of the middle ear, perforation of the tympanic membrane, or cicatrices, should be rejected.

With regard to equilibration and muscle sense, aviators coming out of dark clouds or fog had often found themselves flying one wing down, and it had been recorded that some had flown upside down without knowing it. For this reason, and as the result of an experiment carried out on himself, Mr. Graeme Anderson believed that most of the impressions which control balance in flying came through the eyes; nevertheless he thought that every candidate's equilibration, muscle sense, and vestibular reactions should be tested.

It was important that the aviator should possess normal reaction times with regard to vision, hearing, and touch—all parts of the reflex arcs involved must be intact. These reaction times were tested by means of the d'Arsonval chronometer. The normal visual reaction

time was 19/100 of a second, but in unsuitable candidates might be slowed down from 28/100 to 48/100 of a second. The auditory reaction time usually was 14/100 of a second, but might be delayed from 17/100 to 33/100. The normal tactile reaction time was 14/100 of a second, but might be slowed from 20/100 to 39/100. All the reaction times were found delayed if the candidate was physically or temperamentally unfit, as in disease, worry, cold, fatigue, or after excesses.

In testing emotional reactions—the influence of the emotions on the respiratory rhythm—the vasomotor control and tremor was recorded graphically by the method elaborated by Dr. Lepper. The aviator had round his chest a pneumograph, in his left hand a trembler, and round two fingers of his right hand a pneumatic *doigtier*. All these were connected by rubber tubes to stylets writing on a blackened cylinder; thus were recorded the respiratory rhythm, any tremor present, and the vasomotor control. Behind the candidate a revolver shot was fired or a magnesium flare set off, and on the smoked paper a record was made of any variations. In the best type of pilot with good nerves the effects recorded were of short duration, whilst in unsuitable ones the respiratory rhythm remained increased for some time, there was marked tremor and peripheral vasomotor constriction.

DISCUSSION.

Fleet Surgeon R. C. MUNDAY, Medical Administrator of the Air Force, said that the ideal we had to aim at was on the one hand to exclude from aviation all those who, from medical causes, would swell the non-effective lists, the casualty returns, the number of fatal accidents, and the number of crashed machines; while, on the other hand, at this crisis in the national fortunes, we must ever strive to attain such perfection of method in examination that we prevent no man from serving the King and country in the air who was fit to do so. To attain this we must see that every member of the examining staff was keen and efficient, and supplied with all the apparatus required, the room in which he worked reasonably quiet, spacious, well lighted, sufficiently warm, and properly ventilated. There must be a sufficient number of examiners to prevent overwork and brain fatigue towards the end of the day from clouding their judgement and relaxing their keenness and alertness, and to afford ample time for the careful compilation of records of each case, so that our standards might be checked by statistics as to the after-history of each candidate. Time must also be available for intercommunication, consultation, and conference between examiners. They should gain practical experience of the medical aspects of aviation by periodic and sufficiently extended residence in medical charge of aerodromes. Most of the above conditions were now fulfilled at the Commissions Board at Hampstead, or were in course of attainment. There was no finality in the work of seeking the best method of testing candidates for aviation; we must keep abreast of the rapid progress made in the art of flying and the continual improvement in the design of machines, and do all we could to base our selection of pilots on a sound foundation established on practical experience of the after-history of the candidates selected, combined with results of research on the medical aspects of aviation conducted by British and foreign workers. It was absolutely necessary in order to avoid waste of good material that standards of fitness, and especially of vision, should be graded in accordance with the various flying duties. Reasonable latitude of standard might be allowed to all grades of flying men except those who pilot, or observe from, or act as gunners in, fighting machines. There must be no doubt about the accuracy of colour vision in all cases. The question of heterophoria was of vital importance. Trustworthy tests for the acuity of night vision were being worked out in collaboration with Professor Spearman of University College. With regard to venereal disease, he considered that no candidate should be passed within two years of the last manifestation of active syphilis, and much would then depend on the nature and extent of the treatment he had received and on his Wassermann reaction. He was strongly in favour of no alcohol being consumed at any aerodrome until the flying was over for the day, and then in limited quantities. Even moderate doses of alcohol might have fatal effects if flying was performed while the drug was still acting or reacting on the cardio-vascular and nervous

systems. We should not be too sweeping in our rejection of candidates who had suffered from malaria. The degree of severity of attacks, the condition of the viscera, the nature of the treatment received, and the habits of the candidate must be taken into account. He suggested that the speed of the machine was a factor to be considered in deciding whether an aviator was for the most part dependent on impressions conveyed through the eyes for his sense of balance, or on muscle sense and vestibular reaction. The attitude of the aviator in his machine was of great importance during a steep spiral. If he maintained the usual attitude, the centrifugal action must seriously affect the cerebral blood pressure, whereas if he leant back as far as possible, centrifugal action on the brain was almost nil.

Surgeon-General Sir W. H. NORMAN, Medical Director-General R.N., laid stress on the importance of vision and good colour vision.

Lieut.-General T. H. GOODWIN, Director-General A.M.S., said that in America, where careful tests were being carried out, examiners had told him that they had noticed that good pilots were usually bad sailors.

Mr. ERNEST CLARKE insisted on the importance of perfect vision. Every man should have his vision tested under a cycloplegic. Simply testing with a + glass was not sufficient. The condition of the eye had a large amount to do with accidents; stereoscopic vision was very important, especially in landing. Night flying was a very severe strain, and required absolutely perfect vision.

Captain H. D. BRIGGS, R.N., said that simple methods of examination were necessary. The candidate should be looked at from the human point of view. With regard to vision, glasses were a disability and a danger, and he suggested that a candidate who could see well without them should not be turned down for a visual defect. He always repressed alcohol among aviators. Those with doubtful vision should fly alone, as they had no right to involve others in a risk which they took themselves. Good hearing was important, so that defects could be detected.

Sir WATSON CHEYNE, Bt., M.P., emphasized the need for specially trained medical officers.

Major H. SMURTHWAITE said that men flying at an altitude of 20,000 feet had told him that they invariably took a deep breath every 1,000 feet, and he thought that the sensations experienced by them were connected with the question of blood pressure. He had examined men before going up and after coming down with regard to hearing, bone conduction, etc., and he thought that the loss in bone conduction was probably due to the effect of a change in blood pressure on the semicircular canals. We should try to obviate the change in atmospheric pressure in some way.

Sir JAMES GALLOWAY, Chief Commissioner of Medical Services, Ministry of National Service, asked for something in the nature of a code of instructions as to the medical examinations to be carried out in these cases as the best way of getting standardized and therefore useful work; especially would he ask for some standardized method for the examination of colour vision.

Mr. L. VERNON CARGILL agreed as to the importance of heterophoria as a cause of accidents. Colour vision should be tested by the Edridge-Green lamp. Stereoscopic vision and a perfect visual field in each eye were very necessary.

Major H. C. P. LANGDON, President of the Commission Board, R.F.C., said that no likely officer should be rejected. There was great difficulty in finding out during the medical examination whether a man had the flying temperament. About 10 per cent. broke down during instruction, and these were unsuitable temperamentally.

Major MARTIN FLACK said that there were three important points in the examination of candidates—sympathy, temperament, fatigue. Sympathy was necessary in every medical officer who had to deal with aviators. He had to realize that he was in charge of a human machine, and must see that each separate part was in order. He had been attempting to devise simple tests by which the reaction of the normal human machine could be discovered. Speaking of temperament, he said that about 40 per cent. of picked pilots gave a history of concussion of varying degrees. The flying temperament predisposed to concussion, but here we were dealing with the man who could recover from concussion, and was

therefore a suitable flying man. With regard to fatigue, pilots should be examined at the end of training to determine how they had stood the stress. The time to grade was after the period of training.

Dr. F. J. POYNTON, Surgeon-General H. D. ROLLESTON, R.N., and Captain T. S. RIPPON (School of Instruction, R.F.C., Hendon), also spoke, and Surgeon GRAEME ANDERSON briefly replied.

FEEDING AND DISEASE.

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on March 8th, Captain M. GREENWOOD, of the Lister Institute, and Miss CECILY M. THOMPSON reported the results of an epidemiological study of the food problem. In an introductory account of the present state of physiological knowledge it was pointed out that, although certain matters—such, for instance, as the precise significance of the specific dynamic energy of foodstuffs—were still obscure, “the real difficulty of the subject is not so much uncertainty respecting the justice of the physiologists’ conclusions as the quantitative application of principles themselves clearly established.” In the second section of the paper the problem of muscular efficiency was discussed, and it was shown that existing knowledge is insufficient for the formulation of general rules, that each class of work must be specially considered with particular reference to the external conditions under which it is carried out. In the third section of the paper the statistics of consumption were reviewed, and it was shown that in them the relation between energy used and surface was not so close as might be expected on general grounds; the authors concluded that the necessary uncertainty attaching to such data explained the lack of close concordance. They then gave a minute analysis of some data due to Amar with reference to muscular work, which they showed were fully concordant with physiological expectation. Standard tables giving the probable energy need for workers of different weights and doing different amounts of work had been calculated. A table containing Lefèvre’s results on the heat loss of a clothed man exposed to different temperatures and air velocities was also exhibited; the importance of this aspect of the matter and the value of Hill’s investigations upon rates of cooling in connexion with rationing were emphasized. In the concluding section of the paper the effects of food shortage were discussed, and it was pointed out that a majority of the recorded famine sicknesses were not pure hunger effects, shortage of fuel and antecedent or coincident epidemic disease being chiefly responsible. The siege of Paris in 1870, that of Kut-el-Amara in 1915, and the historical outbreak of disease at the Millbank penitentiary, mentioned recently (p. 239), although not pure famine effects, approximated more nearly to such a condition than any others recorded. From a study of the sequence of events in these cases in relation with the energy value of the diets consumed, it appeared that in each case the onset of sickness was gradual, and that its form depended upon local epidemiological considerations. The authors held that there was no one disease which stood in a peculiarly close relation to inanition; that there was a general and gradual lowering of resistance to all forms of infection.

In the discussion which followed the reading of the paper Dr. LEONARD HILL, F.R.S., enlarged upon the importance of paying attention to the effects upon metabolism of external conditions, and detailed the results of experiments made by himself and Major Martin Flack upon the effect of exposure to wind upon the respiratory metabolism. Professor A. D. WALLER, F.R.S., said that his own observations were concordant with the views expressed by the authors of the paper. He had made a special study of prison dietaries, and the great differences in health and power to work which resulted from variations of even two or three hundred calories in the average energy value of the diet were most impressive. In the course of his reply, Captain GREENWOOD remarked that any student of the food problem must be struck by the need for co-operation between the physiologist and the administrator. Few events had more clearly demonstrated the truth of the contention, so long and so vainly urged, that national efficiency depended upon the utilization of scientific knowledge.

Reviews.

GLAUCOMA.

WHEN a new book is presented for study, and a book which is intended to survey the whole range of pathology and treatment of some disease, it is of interest to turn back to the writings of our professional forbears to see what they knew of and what views they held on the particular problem under consideration. Nearly ninety years ago Mackenzie wrote his *Practical Treatise on the Diseases of the Eye*, fixing for us the best thought of his time and recording the best of his own observations. Glaucoma was then a mystery to the minds of most; it had only just escaped confusion with cataract, and, as the lens was proved innocent of the cause of the blindness, it was sought to fix the strange appearance of suffusion or opacity upon the vitreous. Yet Mackenzie made note of the characteristic “preternatural firmness of the eye to touch, evidently arising from over-distension of the tissues”; and still more definitely, “the pressure of the accumulated fluid within the eye is probably the cause of the total blindness which results at last.” He went so far as to write: “Puncturing the sclerotica and choroid might prove serviceable by relieving the pressure of the accumulated fluid on the retina.”

Taken out of their original setting, such passages as these appear to indicate a very real knowledge of the condition of glaucoma, and they do indeed indicate no little comprehension of it; but when we read, on the same page as the advocacy of scleral puncture for the relief of tension, the recommendation of the day-by-day use of belladonna for the dilatation of the pupil of the glaucomatous eye, we realize that these observations of Mackenzie were only the promise of a new day, which was to be slow to come. For it was twenty years later that the discovery of the ophthalmoscope enabled Weber to see the pressure effect in the cupping of the optic disc.

Colonel ELLIOT’S new book on *Glaucoma*¹ is a worthy and illuminating statement of the knowledge we have attained to in this day. It is described on the title page as a “text-book for students of ophthalmology,” but it may very well reach a yet wider audience, for the lessons of the problem of glaucoma are of no limited application, because of the special phenomenon conditioned by the encapsuled organ of vision; these same problems are found throughout the body, wherever filtration, secretion, and blood pressure determine the vitality of an organ. Further, glaucoma is not a disease of the eye alone, for as Lagrange, the French ophthalmic surgeon, has said, glaucoma is a sick eye in a sick body.

Colonel Elliot’s book treats of the whole field of the disease systematically. After an introduction dealing with nomenclature, the anatomy of the parts concerned is described, and a brief historical survey given. There succeeds a chapter on the intraocular pressure and tension of the eye, in which the physiology of the secretion and filtration of the aqueous, and the causes of its flow, are considered. To the student this chapter will be the key to the appreciation of glaucoma, for in so far as he can grasp the physiological problem presented to him will he be able to understand the complexity of the disease and the difficulties attending its successful treatment. The author has done his work well—each theory enunciated is stated plainly, and the bearing of its truth or partial truth well shown. The subject matter of the chapter on the etiology of glaucoma is a fine illustration of the manner in which, step by step, the tortuous path of discovery has been traced by worker after worker, each following the clue furnished by the other, while at other times whole vistas of knowledge have been unfolded by a discovery, small in itself, but momentous in its bearing. In this field the labours of British workers have been particularly fruitful, and the names of Priestley Smith, Thomson Henderson, and Arthur Thomson stand out. The author has paid generous tribute to their work, and in particular to that of Priestley Smith, “whose careful, painstaking and accurate life-work has

¹ *Glaucoma. A Textbook for the Student of Ophthalmology.* By Robert Henry Elliot, M.D., F.R.C.S., Lieut.-Colonel I.M.S. (ret.). London: H. K. Lewis and Co., Ltd. 1913. (Demy 8vo, pp. xvi + 545; 153 figures. 21s. net.)

made to science a contribution of nearly everything worthy of credence that is to-day comprised in our knowledge of glaucoma. . . . There is no branch of the subject that has not been illumined by his researches. The work that he did in his early years has never yet been seriously challenged, and commands to-day, as it rightly should, the practically unqualified acceptance of all those who are best fitted to give an opinion on the subject."

The chapters on the clinical aspects of glaucoma form as instructive a clinical essay as could be desired, and not least helpful to the student will be the several illustrations and diagrams in the text. In the chapters on treatment ground is traversed which will be familiar to readers of current medical literature. The author is of opinion that the "expectant treatment" of glaucoma is a broken reed; and he "is convinced that, if taken in the mass, the best results will be found in the clinique of the surgeon who operates the moment that he is satisfied in his own mind that glaucoma is present." He wholeheartedly echoes the words of de Wecker: "If meiotics have never cured a case of glaucoma, they have prevented many glaucomatous patients from being cured."

The last hundred and fifty pages of the work are devoted to the discussion of surgical treatment—iridectomy and sclerotomy. The bases of these operations, and the advantage of this or that procedure according to the type of the disease are considered. The success of iridectomy in acute glaucoma made its failure in chronic glaucoma the greater perplexity to the disciples of von Graefe. It was not until de Wecker appreciated and insisted upon the important part played by the filtering cicatrix left after iridectomy that both success and failure were explained, and a long series of endeavours initiated to secure such a cicatrix in all cases of glaucoma without creating an additional danger to the eye. To Lagrange falls the honour of having first secured this end: by a modification of the original iridectomy technique, as simple as it was effective—the removal of one lip of the wound in the coat of the eyeball with the scissors. On this basis a dozen or two of variant operations have been devised and practised by ophthalmic surgeons. All of these methods are noticed by Elliot, their merits and demerits discussed, and, in particular, the removal of a piece of the sclero-corneal margin by the cut of a trephine, as advocated by himself and now widely practised.

This book on glaucoma has been well done. Colonel Elliot is to be congratulated on the product of his labours. The publishers also are to be congratulated on the manner of its presentation at a time when book production is no easy business.

GARRISON'S "HISTORY OF MEDICINE."

DR. FEILDING H. GARRISON'S *Introduction to the History of Medicine*² has met with well deserved success; the first edition in 1913, which was reviewed at length in these columns some time after (1914, i, 1241), was reprinted in the following year, and a new edition was called for last year. It has been most thoroughly and minutely revised and contains 142 more pages than before. Admiration for the enormous labour involved and the fascinating style in which both the broad outlines and the details of medical history are portrayed is the impression left on the reader's mind. In a modest preface Dr. Garrison refers with a light touch to the criticisms evoked by the appearance of his book, and gently meets Neuburger's complaint that he "sees things through English spectacles" with the assurance that he has written impartially, and that it would be difficult to find anything unfair to German medicine or to the modern German organization of science. Although it may be true, as Dr. Charles Singer in a letter to the author says, that the history of medicine is a history of ideas and that biography is only of value in so far as it bears on ideas, the ordinary reader will get the greatest pleasure from the human interest excited by the very large number of short biographies, which do much to show the gradual advance of medical science. These biographies are admirably illustrated by portraits, and the student anxious for further information will find a ready guide to the original sources in the numerous references. It is

indeed no exaggeration to compare Dr. Garrison's introduction to medical history with the *Index Catalogue* of the Surgeon-General's Library in which he works, as regards its value as a source of references. But it would be the greatest mistake to convey the impression that the matter of the narrative is less complete in its way than its bibliography, and it is difficult without what might appear to be exaggeration to do justice to the excellence of Dr. Garrison's book.

NOTES ON BOOKS.

OF the making of books on the sexual instruction of the young there seems to be no end, and it is possible that too much public attention is being directed to the subject. With this reservation we may, nevertheless, welcome two recent works by medical women who are especially competent to advise parents on this difficult and delicate matter. DR. MARY SCHARLIEB maintains throughout her book, *How to Enlighten Our Children*,³ an admirable compromise between idealism and common sense, and it is written in a style which is simple and direct without being namby-pamby. DR. BEATRICE WEBB'S pamphlet, *The Teaching of Children as to the Reproduction of Life*,⁴ deals much more briefly with the same subject, and from much the same point of view, but is, perhaps, more suitable for parents in a lower educational stratum. Medical men may be glad to know of these two works, which between them seem to cover quite adequately the needs of all social classes and should obviate the necessity for any further publications upon this topic for some time to come.

The second edition of Dr. BALLANTYNE'S well-known *Encyclopaedia Medica*⁵ has reached its fifth volume (Felix Mas—Heart). The editor has secured a distinguished body of collaborators in this as in the previous volumes of the *Encyclopaedia*, and the articles it contains reach the customary high level of excellence. It is needless to add that the work is one that should be found in every medical library, and also on the shelves of many a general practitioner of medicine.

In *A History of Departed Things*⁶ Mrs. HENRY HEAD tells the story of a woman's inner life by means of a series of letters to which the heroine's sister plays the part of the ancient Greek chorus. The scene opens with a sketch, all too short, of academic life in Oxford about the early eighties—at least so internal evidence, the reference to the recently opened high school for girls, would suggest. To whet the reader's appetite is a sign of the writer's success, and in this instance the desire for more can at once be gratified by turning to Mrs. Humphry Ward's "Recollections" in the March number of the *Cornhill Magazine*. The heroine, one of a family somewhat remarkable in all being born with brown eyes, never grew old, was devoted to books, and perhaps rightly regarded Mallock's *New Republic* as the wittiest book ever written. Through the early pages there runs a presentiment of tragedy fully borne out by subsequent events. The heroine's character is a human document cleverly worked out, and the male characters—three doctors, two of whom are successively the heroine's husbands—are attractively drawn.

The first number of *British Artists at the Front*,⁷ issued by *Country Life* as a sequel to *The Western Front*, contains a series of drawings by Mr. Nevinson, who, though he has paid homage occasionally to some modern eccentricities, is too sound an artist to be dominated by them. The drawings here reproduced of what the flying man sees are perhaps the most novel, but some of the figures and landscapes are very striking, especially, perhaps, those of a mule team and of reliefs at dawn, and a characteristic sketch of the road from Arras to Bapaume.

Garrison, A.B., M.D., Principal Assistant Librarian, Surgeon-General's Office, Washington, D.C. Philadelphia and London: W. B. Saunders Company. 1917. (Pp. 905. 28s.)

British Medical Journal.

SATURDAY, MARCH 16TH, 1918.

A MINISTRY OF SCIENCE.

THE task of preventing the pollution of the atmosphere by coal smoke is likely to be greatly helped in the future by the labours of the Fuel Research Board of the Department of Scientific and Industrial Research. One of the main questions to which it is devoting its attention is whether the 35 to 40 million tons of raw coal used every year for domestic heating could be wholly or partially replaced by smokeless fuel, solid and gaseous, prepared by the carbonization of the raw coal now used. To answer this and cognate questions will involve elaborate experimental inquiries, including an investigation into the carbonization of coal at low temperatures; for this and other purposes the Board is establishing a large fuel research station on a site adjoining the works of the South Metropolitan Gas Company. The Fuel Research Board, of which Sir George Beilby, F.R.S., is director, is one of the many sections of the Department of Scientific and Industrial Research established in July, 1915, which, though technically a committee of the Privy Council, is practically an independent body. It is directed by an advisory council of scientific experts, who administer the Imperial Trust for the Encouragement of Scientific and Industrial Research, which has been provided by the Government with a fund of one million sterling. The documents relating to its foundation expressly recognize that the independence and initiative of the British manufacturer have contributed largely to his success in the past, that he ought to be helped in undertaking and developing scientific research as a means of enlarging his output and improving its quality, but that the help must increase his independence and initiative, and must avoid chaining him to the routine of Government administration. It must also enlist his active support, and the department proposes to expend the fund at its disposal on a co-operative basis in the form of liberal contributions towards the income raised by voluntary associations of manufacturers established for the purpose of research.

Constitutional precedent for the establishment of a quasi-independent department under the wing of the Privy Council could be found, and the antenatal history of the Local Government Board may afford an example; but the only directly comparable body now in existence would seem to be the Medical Research Committee, which, however, is under the wing not of the Privy Council, but of the Insurance Commissioners. It consists of ten members, of whom eight, including the secretary, are men of science; two laymen act as chairman and treasurer respectively. The Advisory Council of the Department of Scientific and Industrial Research consists of seven distinguished men of science; its chairman and secretary are educational experts. The department has already approved and assisted a large number of scientific investigations of industrial importance beyond those undertaken by the Fuel Research Board, and in addition to the capital sum already mentioned it is able to command a substantial annual vote from Parliament. The Advisory Council has a number of assessors, among whom are Professor Wyndham R. Dunstan, Director of the Imperial

Institute and formerly lecturer on chemistry at St. Thomas's Hospital (representing the Colonial Office), Sir Arthur Whitelegge, K.C.B., M.D., of the Home Office, and Sir Walter Fletcher, M.D., F.R.S., secretary of the Medical Research Committee. During the second year of its existence, which ended on July 31st, 1917, it took over from the Royal Society the property of the National Physical Laboratory, together with the responsibility for its maintenance and development. When noticing its last annual report, we observed that the wider aspects of the work of the new department concern the medical profession, and that in so far as it stands for the organization and endowment of research as a whole its aims and methods deserve our close attention. Though primarily established to encourage the application of scientific research to industrial methods, it seems possible that the department may become the rallying point of other scientific branches subsidized by the Government and may eventually develop into an independent Ministry of Science.

THE COLLAPSE TREATMENT OF CONSUMPTION.

MANY years ago the late Dr. Cayley published a case in which he had been able to check a severe hæmorrhage from the lung by the induction of artificial pneumothorax. The diseased lung on the affected side became collapsed, and the immediate danger of death by bleeding was averted. The proceeding, although obviously successful, was at the time regarded as heroic, and no further cases appear to have been recorded. In 1882, however, Dr. Forlanini of Pavia brought forward the suggestion that in certain cases of advanced unilateral tuberculosis of the lung it might be possible to arrest the spread of the disease by the artificial production of collapse of the affected organ. Six years later he made known his first results, which led to favourable conclusions. In 1898 Dr. Murphy advocated a similar line of treatment, and in 1906 the method was being used extensively, especially in the German clinics.

Since 1906 a very large number of cases have been treated, and an interesting report on the whole subject has been made¹ by Dr. W. N. Beggs, of Denver, Colorado, and Dr. C. L. Miner, of Asheville, North Carolina, who have both had extensive practical experience. On all main points it agrees with that of former workers in the same field, and it may be noted that, as regards immediate relief to present symptoms, the induction of collapse of the diseased lung is undoubtedly successful, and especially so in cases of persistent hæmorrhage. Cough and sputum, pyrexia, sweating, and other evidences of systemic poisoning rapidly disappear, and for a time, at any rate, the disease appears to be checked. These happy results, however, do not occur in all cases; hence the greatest care is needed in the selection of cases in order to avoid the many risks that attend the method. The most favourable case is that of unilateral disease, limited to the upper lobe, in which there is reason to believe that no pleuritic adhesions are present to prevent collapse of the lung when the pleural cavity is filled with nitrogen. So successful have some of these cases proved, that the suggestion has been made to induce pneumothorax in the early stages. The procedure, however, is not free from danger, even in skilled hands, and the published results of natural arrest of incipient disease are so good that this idea has not been pressed, except by a few enthusiasts.

¹ *American Review of Tuberculosis*, November, 1917.

In the great majority of cases it is extremely difficult, even with the aid of the skiascope, to ascertain with any approach to certainty the presence or absence of adhesions. In very many instances the treatment has failed because the adnient lung has not been in a condition to collapse, and it may well be inferred that such failure has entailed a good deal of suffering to the patient and disappointment to his medical adviser. Hence there should always be a clear understanding as to the actual risks that have to be faced. If the disease is advancing rapidly and is as yet limited to one side, there would seem to be very reasonable hope of benefit, both immediate and future, and records prove that the disease may be arrested and full working capacity restored after a prolonged period of treatment. In such instances the collapsed lung ultimately expands again, but such expansion is of necessity slow. In the less definite cases the degree of success or failure must depend upon the capability of the lung to shrink and upon the integrity of its fellow. The cessation of active disease on one side has sometimes been followed by increased activity on the other, and this possibility must always be borne in mind. The paper to which we have referred contains numerous instances of untoward happenings, not due to neglect, but arising from causes due to imperfect diagnosis of the actual conditions present.

The conclusions to be drawn are that in a limited class of case a genuine arrest of the disease may be brought about by putting the whole lung out of action for a period, and that in less favourable instances a great deal of present relief may be afforded, even though life be not greatly prolonged. But there are many considerations to be weighed before so serious a procedure can be adopted in doubtful cases. Manipulative skill and scrupulous care in applying it are essential, and hence the treatment can only be satisfactorily carried out by experts. Even in the most experienced hands, and with all possible care to prevent mishaps, the course of recovery is often checked by such occurrences as hydropneumothorax or pyopneumothorax, or by the development in the compressed lung of abscesses which burst into the pleural cavity, and by other unavoidable accidents. The collapse treatment is likely to be more widely adopted as years go on, as brilliant successes are from time to time recorded, but present experience would seem to limit its use to cases with unilateral and strictly localized lesions.

MEDICAL STUDENTS AND MILITARY SERVICE.

THE Minister of National Service has issued detailed directions with regard to the "protection from military service of medical students" now in civil life (National Service Instruction No. 35 of 1918). These may be looked upon as the obverse of Army Council Instruction No. 153 of 1918, which governs the release of medical students from the ranks.¹ (1) A medical student who on March 5th, 1918, was a full-time student at a recognized medical school, and had at that date passed his professional examination in chemistry, physics and biology (or botany and zoology) for a medical degree or licence is not (subject to paragraphs 5, 6, 7, and 8, below) to be called up, whatever his medical category or grade, so long as he remains a full-time medical student. (2) A medical student who on March 5th, 1918, was a full-time student at a recognized medical school, and furnishes to the A.D.R. of his area a certificate from the dean, or corresponding official, of his medical school that he should be able to

pass his first professional examination as above on or before July 31st next, is not to be called up before July 31st next, whatever his medical category or grade. If he passes that examination by July 31st next his case will thenceforward be treated as if covered by paragraph 1. If he does not pass by that date he will forthwith be called to the colours if otherwise available and required for service, unless he comes within the terms of paragraph 3. (3) A medical student (other than one whose case is covered, or is to be treated as if covered, by paragraph 1) who is or becomes a full-time student at a recognized medical school, and who is in Category B 2, B 3, C 2, or C 3, or is placed in Grade 3, is not (subject to paragraphs 4, 5, 6, 7, and 8) to be called up, so long as he remains a full-time student, without reference to the Director of National Service for the region. (4) A student protected under paragraph 3 who does not within twelve months of commencing his professional studies at a recognized medical school pass his first professional examination as above, will forthwith be called up if otherwise available and required for service. (5) A student protected under this Instruction who fails to pass his professional examination in anatomy and physiology within thirty-six months of commencing his professional studies at a recognized medical school will similarly be called to the colours. (6) For protection under this Instruction a student must be enrolled in an O.T.C. and fulfil after enrolment the conditions of efficiency laid down for medical cadets. (7) Protected students delaying qualification unnecessarily, or otherwise not satisfactorily pursuing their studies, are to be referred to the Director of National Service. (8) Protection will be withdrawn from a student who has been requested in writing by the Ministry of National Service to offer himself as a surgeon probationer, R.N., and has not within twenty-one days applied for enrolment as such. The remaining paragraphs of the Instruction—which supersedes all previous instructions relating to the protection of medical students now in civil life—deal with formalities to be observed in the matter of certificates and of applications to tribunals in respect of medical students not hitherto called up but now no longer protected.

PARALYSIS OF VASCULAR ORIGIN.

INTERMITTENT claudication or intermitting limping, seen in association with some forms of arterial disease, especially the thrombo-angeitis obliterans of Buerger and Parkes Weber, is characterized by pain, paraesthesia, and difficulty in walking after attempting to do so for some time. Here a definite causal relation between the vascular changes and the symptoms is recognized, but when paralytic, trophic, vasomotor, thermic, and secretory disorders follow wounds of the extremities, the responsible factor has generally been regarded as nervous in origin. Recently, however, the frequency of arterial wounds has directed attention to the part played by vascular disturbances in the production of the nervous manifestations, and in a recent paper in these pages (1918, i, 199-203) Captain Harold Burrows described ten cases of "angiotoxic paralysis" with sensory changes, which fell into two groups, the first of ischaemic paralysis with obliteration of the pulse in the limb distal to the injury, and the second of reflex paralysis with arterial injury not completely blocking the vessel. Dealing with the same classes of cases in an article on arterial obliteration and circulatory disturbances in the limbs in the wounded, Desplats and Buquet¹ put forward the ingenious interpretation that some paralytic and anaesthetic, accompanied by trophic lesions and the reaction of degeneration, are entirely due to permanent or temporary ischaemia of the terminations of the nerve trunks resulting from the vascular lesions. Formerly these nervous disturbances associated with arterial injuries were ascribed to concomitant division, contusion, or other gross

¹ BRITISH MEDICAL JOURNAL, February 23rd, 1913, p. 237.

¹ R. Desplats et A. Buquet, *Rev. de méd.*, Paris, 1915, **xxv**, 573-613, parus en Février, 1913.

damage to the neighbouring nerve trunks, and no doubt in the majority of such cases primary lesions of the nerves and artery coexist, but in a certain number of instances the primary cause is exclusively arterial obstruction. These paralyses of vascular origin are much more obvious in the upper than in the lower extremities, and the explanation is that the collateral circulation in the lower limbs is relatively so imperfect that gangrene is prone to occur and mask the paralytic and sensory changes. The clinical features pointing to a vascular origin of the nervous manifestations are paralysis of a terminal form, involving the muscles of the hand and spreading upwards, with the reaction of degeneration and atrophy, anaesthesia most intense at the ends of the fingers, and spindle-like and bulbous deformity of the digits. Both experimental and clinical ligation of the axillary artery, especially in its dangerous zone between the origins of the subscapular and profunda branches, may produce these paralytic, sensory, trophic, and vasomotor disturbances, which it is concluded are due to degeneration of the nerves at their terminations. Transient or incomplete ischaemia may cause somewhat similar results, and reason is shown for regarding the nervous disturbances following somewhat prolonged application of a tourniquet or Esmarch's bandage, crutch paralysis, and Volkmann's ischaemic paralysis as manifestations in a minor degree of the ischaemia caused by complete obliteration of the axillary artery.

CHRONIC INDUSTRIAL EXPOSURE TO HIGH TEMPERATURES.

A common and serious problem of industrial hygiene is the combination of a high atmospheric temperature and unusual humidity which has arisen since steam was substituted for water power. Watkins,¹ writing from experience in the United States, mentions among the industries in which the employees are exposed to exceedingly high temperatures, and in some instances to extraordinary conditions of humidity, sugar refineries, paper and flax mills, laundries, tanneries, large kitchens, stove-holes and fire rooms of ships, glass factories, steel blasts, and chemical works. Acute symptoms may occur in the form of heat exhaustion or heat-stroke. The commonest effect of chronic exposure to heat is lowered physical efficiency and diminished resistance to fatigue and disease; arthritic and muscular rheumatism, arterio-sclerosis, and chronic skin diseases occur; and from radiant heat reddening of the skin with changes up to the second degree of burns, and temporary loss of vision, may result. These dangers to health can be greatly mitigated or practically eliminated if due consideration is given to the subject and the necessary steps taken for the protection of the workers. A certain amount of adaptation occurs in some instances, but this may be due to instinctive alterations of clothing, exertion, and diet. As far as possible the source of the heat should be placed away from the workers, and should be covered by a water jacket, asbestos, or other substance having similar properties. Free natural ventilation, exhaust fans and screens, goggles, asbestos aprons and leggings to protect the workers from radiant heat, are advocated. Loss of heat from the workers' bodies is promoted by the wearing of thin, light, absorbing clothing such as cotton, from which evaporation of the perspiration can readily occur. Watkins considers that in general the air of workrooms should not exceed 70° F. by the wet bulb; at 72° F. much body surface must be exposed and a perceptible air current passed over the body if work is to be done without unduly raising the worker's temperature; if the wet bulb registers 85° F., the body temperature rises and work is impossible. The relative humidity is thus the essential index of the conditions in the workrooms. The air should be kept in motion by fans, and it is important that an

ample supply of water should be drunk in small quantities at frequent intervals to make up for the loss by evaporation. As physical exertion raises the temperature, short spells of labour should be instituted. The heat-producing values of protein, carbohydrates, and fat are as 20:10:7, and, in order to reduce the heat production, meats and fats should be restricted, and starches, fruits, and green vegetables increased.

DIET AND MALIGNANT DISEASE.

For ages man has cherished the illusive hope that malignant new growths are—or, if they are not, will presently prove to be—curable by diet. A growing cancer must feed on something; what, then, could be more reasonable than to argue that a suitable limitation of the patient's dietary would arrest the tumour's growth, or even lead to its disappearance? The question is one that lends itself to experimental investigation, and it has recently been attacked once more by Mr. J. C. Drummond,¹ using as his material rats (*Mus norvegicus*) infected experimentally with rat sarcoma. The method of investigation employed was to determine the influence of dietary inadequacy in checking the growth of these tumours in young rats. The dietary inadequacies tried were five—namely, a low protein content, the use of a protein possessing a relatively low nutritive value, a diet lacking certain indispensable amino-acids, and diets lacking certain accessory growth-promoting factors characterized respectively as "fat-soluble A" and "water-soluble B." of the vitamine class. The author's conclusions are interesting, though they cannot be called hopeful. He finds that if the host is thus partially starved the tumour will continue to grow so long as it possesses a satisfactory blood supply, although the rat, its host, may not grow. There is evidence that this proliferation will proceed at the expense of the host's tissues until these are no longer able to make good the dietary defect. When this stage is reached the tumour will grow more slowly, and this occurs comparatively early when the diet is deficient in either tryptophan or water-soluble accessory factor B. There is no evidence that the cells of tumours possess powers of synthetical action which the normal cell of similar type does not possess. Finally, it does not appear possible to inhibit the growth of the rat sarcoma by such dietary restrictions as these without seriously impairing the nutrition of the rat. There is little hope, therefore, of bringing about an alleviation of the analogous disease in man by the imposition of dietary restrictions such as those described above.

ELECTRIFIED BABIES.

SIR JAMES CRICHTON-BROWNE has told a story in the *Times* which, as it has a moral, may usefully be noted here. Four years ago a statement was circulated to the effect that of two groups of school children of the same age and in similar circumstances, that which worked in an electrified atmosphere was found at the end of six months to have grown faster, to be in better and more vigorous health, and to be more successful in examination tests than a control group. Inquiries addressed to Professor Arrhenius, director of the Physico-Chemical Department in the Nobel Institute, brought a reply which put a very different complexion on the story. It proved to be true that he had experimented with about one hundred children, of whom fifty were subjected to electrification in a room where the potential in the upper part was about 1500 volts higher than at the floor. The result was strongly in favour of the electrified children, as indicated by their increase in weight and health. It turned out, however, that the children were infants under one year, in an orphan asylum, so that the story about their being better at examinations was a pure invention, and, moreover, it was discovered that the

¹ J. R. Watkins. Public Health Reports, issued weekly by the United States Public Health Service. 1917. xxxii, 2111-2121.

¹ Biochemical Journal, Cambridge, 1917, xi, 325.

zealous nurse to whom the arrangements for the experiment had been entrusted had, under a mistaken notion, put into the group for electrification all the strong vigorous babies and into the other group all the weak and ailing. The electrified infants had, therefore, a good start and did no more than maintain their advantage. Later experiments on a larger scale and with a more equitable division of material showed no influence of the electrification one way or the other. What hypothesis the distinguished Swedish professor had in mind when he made the experiment we do not know, but possibly he may have been influenced by the effect of the application of high tension electricity by very thin overhead wires to growing crops. According to Sir Oliver Lodge, this has now passed beyond the laboratory stage and has been giving practical results for some years. Professor Arrhenius may also have been thinking of the advantage said to be obtained by the electrification of seed before sowing. According to Dr. Charles Mercier, farmers in Dorsetshire who gave it a trial on small plots one season, tried it on a few acres the next, and on more acres the third, and are now sowing the whole of their arable with electrified seeds.

BIO-BIBLIOGRAPHY.

THE *Veterinary Review* for February, besides a large number of abstracts which from their bearing on comparative pathology are of general interest, contains two articles written around reviews of great books. One, unsigned, on the birth of modern surgery, deals with Sir Rickman Godlee's *Life of Lord Lister*, and points out that it disproves Stopford Brooke's dictum that a good biography cannot be written by a relative. The other, by Sir William Osler, a former teacher in a veterinary college, based on General Mennessier de la Lance's *Essai de Bibliographie hippique*, shows the difference between a bibliography, which, though not naturally dry, is too often made so by faulty treatment, and a bio-bibliography or the story of the book as part of the life of the author. The word itself appears to be new, although Murray gives "bio-bibliographical," defining it as "dealing with the life and writings of an author." Whether the word be new or not we are, if we mistake not, indebted for the important distinction indicated to Sir William Osler, who speaks with the authority of the President of the Bibliographical Society. As fascinating examples of bio-bibliographies he instances the late W. Prideaux Courtnay's recent bibliography of Samuel Johnson as a better exposition of the working ways of the great lexicographer than Boswell's biography. This hippic bibliography tells the complete story of the French veterinary profession and shows the high position attained through Government support of some of its members, such as Bouley and Chauveau. Among the authors mentioned is Eugene Sue, so famous as a novelist that his medical life is generally forgotten.

TUBERCULOSIS IN THE PACIFIC ISLANDS.

A REMARKABLE illustration of the well-known tendency for tuberculosis to flourish on virgin soils reaches us from a group of islands in the Pacific, of which Tonga is the capital and the seat of government. The disease has become widespread among the people, and is rapidly destroying the young men and women. The mode of life has hitherto been particularly conducive to the development and distribution of the bacillus. The chief medical officer of the Tongan Government, Dr. H. M. Cowen, has taken active steps to combat the evils to which local manners and customs are giving rise, and with the support of the King, George Tabou II, and the Premier, Tu'ivikano, has issued a pamphlet in English with a translation into the Tongan language, in which he has set forth in the simplest possible terms the main facts with regard to tuberculosis, and the means whereby it may be communicated from one person to another. Overcrowded

dwellings with little or no attempt at ventilation, the use in common of cooking and eating utensils, the strange custom of passing half-chewed food from mouth to mouth, especially to children, and numerous other hygienic errors, are in turn pointed out and the risks attendant upon them explained.

THE PAPER SHORTAGE.

THE statement in our issue of March 2nd, on the diminution of pages in the *BRITISH MEDICAL JOURNAL*, was made in consequence of an intimation that the Paper Commission¹ intended to issue an order reducing the licences for the importation of paper and paper-making material in the year beginning March 1st, 1918, to two-thirds of the tonnage imported in the year ending February 28th, 1918. The order as issued in fact reduced the licences to one-half of the tonnage imported in the previous year. This drastic reduction takes effect on a supply which had already been reduced by one-third owing to previous orders by the same authority. The effect will be to render it difficult, if not impossible, to maintain the reduced number of pages in recent weekly issues of the *JOURNAL*. It is clear that under such conditions the preservation of a due balance between the different departments of the *JOURNAL* can only be accomplished by rigid selection and compression of all material published. We appeal to every one preparing any communication intended for publication to apply his critical faculty to his own writing in order to attain the utmost conciseness. As it will not be possible in all cases to continue the practice of sending out proofs of letters or other communications of a like nature, the Editor must reserve the right to shorten current communications which, though they cannot be printed in full, contain matter the publication of which would be of advantage to the profession.

A MOVEMENT has been started by the local women's and men's clubs in Guelph, Ontario, where he was born, to establish a Canadian memorial to Lieut.-Colonel John McCrae, C.A.M.C., who, shortly before his death from pneumonia on January 28th, had been appointed a consulting physician to the British Expeditionary Force in France. Not only was he a man of many interests in medicine but a poet of no mean order. Such a man deserves a memorial to remind future generations of his achievements, which, for want of time, fell far short of promise, and of the nobility of his character.

Medical Notes in Parliament.

Royal Army Medical Corps: The Report on Services in France.—Major David Davies asked Mr. Macpherson, on March 6th, the number of temporary medical officers holding administrative medical appointments in the Army; what percentage of administrative appointments in the Royal Army Medical Corps were held by the regular officers; and whether any steps were to be taken to provide tuition in staff duties to temporary medical officers of proved capacity and experience with a view to their holding such posts. Mr. Macpherson replied he was not clear as to what was meant by "administrative medical appointments." There were large numbers of medical officers holding posts of an administrative nature in the United Kingdom and in various theatres of war, such as heads of hospitals, registrars, sanitarians, deputy directors of medical services, inspectors, controllers of expenditure, etc. To ascertain the particulars sought would involve prolonged inquiry, and it could not be undertaken. There was no occasion for taking the steps suggested in the last part of the question. Major Davies asked whether, in

¹ The Paper Commission has ceased to exist. It has been replaced by a Controller of Paper, who, according to the President of the Board of Trade, by whom he was appointed, has no experience of the subject.

view of the fact that the report of the Committee of Inquiry on the army medical service in France had been conveyed to the Ministry of National Service, Mr. Macpherson could state the reasons for withholding the report from members of the House of Commons; and whether he would reconsider the decision in the matter. Mr. Macpherson: The Council have not yet considered the report, and I cannot undertake to publish it until this stage has been reached. The recommendations are now being investigated by the British military authorities in France.

Disabled Soldiers' Treatment in Wales.—Mr. Hodge informed Major Davies, on March 6th, that after consultation with the Joint (Disablement) Committees for North and South Wales a joint consultative committee had been formed of representatives of both Joint Committees. The first meeting was held on February 23rd, and it was hoped that the combined action thus initiated would have useful results.

Air Medical Service.—In reply to a question on March 6th, Major Baird (Parliamentary Secretary to the Air Ministry) declined to publish the report of the committee appointed last autumn to advise as to the formation of a flying services medical department, on the ground that it consisted largely of administrative recommendations contingent on the adoption of its main proposals. These, as was reported a fortnight ago, were rejected, and a compromise, which Sir Watson Cheyne, M.P., the chairman of the autumn committee, accepted with reluctance, has now been put into force. The medical administrative committees for the medical service of the air force is, as already announced, a mixed body. It consists of the medical Director-General of the navy, the Director-General A.M.S., a physician (Dr. H. D. Rolleston), a neurologist (Dr. Henry Head), a surgeon (Mr. Raymond Johnson), a physiologist (Dr. Leonard Hill), and the secretary of the Medical Research Committee (Sir Walter Fletcher). The Medical Administrator of the air force (Fleet Surgeon R. C. Munday, R.N.), and the Assistant Medical Administrator (Major C. B. Heald, R.A.M.C.) are also members of the committee.

Operations on Poor Persons in Ireland.—Mr. Arthur Samuels (Solicitor-General for Ireland), in a written answer to Mr. Kennedy, said he had read the judgement in *Kenelly* and others v. *Cyril E. Brown*, whereby boards of guardians are debarred from sending poor persons for operations, etc., to extern institutions or city hospitals. He was not aware that any steps were being taken to appeal from the judgement, but representations as to the need for amending the law had been made and would be duly considered.

Motor Dental Outfits.—Mr. Macpherson informed Mr. Pennefather, on March 11th, that the motor dental surgery presented by the Silver Thimble Fund was taken over by the War Office on March 8th, and it would be dispatched without delay to France.

TREATMENT OF VENEREAL DISEASES.

At a meeting of the National Council for Combating Venereal Diseases, on March 12th, at the house of the Royal Society of Medicine, Sir THOMAS BARLOW, who presided, said that the Local Government Board scheme had now been on trial for a year, and he felt sure that after another year treatment centres would have been established in nearly all towns. The minds of many people had been rightly exercised by the statements with regard to tolerated houses in France, but the Council in its policy was not concerned primarily with the moral aspect. It had, however, passed a resolution that it saw no reason to depart from the position of the Royal Commission that any return to tolerated prostitution would be a deplorably retrograde movement, and would not lead to a diminution of disease.

Lady BARRETT, C.B.E., M.D., said that experience at venereal clinics during the last year had shown the need for further beds for infected pregnant women and for women after repeated miscarriages and stillbirths. Gonorrhoea was more difficult to cure than syphilis, especially during pregnancy, and beds were required not only for the child's sake but even more for the mother's. Few, if any, lying-in hospitals had special wards for such cases, and it was not desirable to introduce them into the general wards. Nor was it fair to the women to send them to the work-house or the Lock Hospital with its unpleasant associations. They were either respectable married women, whose infection often dated from the leave of their husbands from the front, or were young girls. The London County Council might provide special beds in association with

existing clinics. In syphilis, should the treatment not be in time to prevent miscarriage or stillbirth, the material would be valuable for examination and research, and therefore it would be useful to have the beds in close association with the clinics; further, as the clinics were mostly at the large teaching hospitals, it was desirable that the beds should be part of the maternity department of those hospitals.

Mrs. BURGE, wife of the Bishop of Southwark, speaking of the case of infected children, said that in-patient treatment at the Lock Hospital was unsatisfactory, owing to the type of case treated there. Out-patient attendances were unsatisfactory because the parents were usually unable to carry out the treatment and take all the necessary precautions. She suggested the establishment of small hospital homes or hostels in the country or the suburbs, but recognized that the difficulties of such an undertaking would be too great for a voluntary association.

Dr. A. F. TREGOLD said that in all the grades of mental deficiency there was one underlying defect, which might be called defective wisdom, and superadded to this were weakness of will, amenability to suggestion, and often erotic tendencies. The defective girl was not able to realize the dangers of illicit sexual intercourse, or to resist temptation, or to profit from a first experience. Many mentally defective persons, owing to war conditions, were now in employment, often away from home, and, in his own experience of the mentally defective girls admitted into rescue homes during the last two years, the majority had venereal disease which had lasted for weeks, and in some cases for months, and during that time the girls had engaged in promiscuous sexual intercourse. No treatment could avail unless such cases were compulsorily detained. The presence of venereal disease in a feeble-minded person should be regarded as making detention imperative. The difficulty arose from the defective supervision of feeble-minded persons. The CHAIRMAN said that the Executive Committee of the Council had agreed to communicate with all magistrates, pointing out that in the case of mentally defective girls brought before them they might, in granting certificates of mental deficiency, consider the presence of venereal disease in the girl as coming under the term "neglect" in the Act.

Dr. W. G. SAVAGE (M.O.H. Somersetshire) complained that the Local Government Board scheme was framed only with a view to urban conditions. In rural districts, owing to the long distances between the villages and clinics, travelling expenses in a large proportion of cases must be regularly paid, but this would not meet the loss of time. He suggested that the clinical medical officer, who should be a whole-time man, should go to the villages, and make a temporary clinic of the consulting room of the local practitioner, with whom he could talk the cases over. With regard to beds there was not much to be hoped for from the local hospitals; but if the break up of the Poor Law was imminent some of the old Poor Law buildings, cleansed from pauper taint, might be made available.

Mr. E. B. TURNER said that he was glad that Lady Barrett had placed in the forefront the ravages of gonorrhoea. He thought that every woman who was pregnant should be encouraged either to put herself under the care of her own doctor, or to go to a prenatal clinic so that she could be carefully treated, and such precautions might be taken that her confinement would not be the septic tragedy it otherwise might become.

Sir FRANCIS CHAMPNEYS pointed out that the majority of poor mothers were attended in confinement by midwives, who could not be left out of such a scheme.

Dr. C. J. MACALISTER described the system at Liverpool by which the midwives sought out such cases before confinement and referred them to the hospitals.

As to the question of infected children, Sir THOMAS BARLOW said that if the general and children's hospitals did their duty the establishment of a number of small separate hospitals would be unnecessary.

THE fourth Cuban Medical Congress in Havana was attended by more than 1,400 members. It was opened on December 16th last by the Secretary of Public Health, and was formally closed on December 22nd by the President of the Republic. Among the subjects for discussion in the general sessions were blood pressure in Cuba, Cuban vital statistics, and the composition of the blood.

THE WAR.

CASUALTIES AND REWARDS: 1915-17.

ATTENTION has very naturally been aroused by the terms in which Mr. Macpherson replied, during the discussion on the Army Estimates on February 25th, to a point made by Mr. Roch as to the recognition accorded to officers of the R.A.M.C. other than those on the Regular list. The statement he was meeting was that, while one of every two of the Regular medical officers had been decorated, only one in fifty of the 14,000 civilian doctors had been decorated. Mr. Macpherson's reply was to the effect that it was natural that more decorations had been given to officers R.A.M.C. than to civilian doctors because the first went out at the very beginning of the war and were established servants at the time. But he also said that most of the civilian doctors were kept at home doing part-time work, carrying on their own practice and also doing civil work in hospitals, so that they had not the same opportunity for decoration given to the R.A.M.C., who were established officers and had been bearing the brunt of work at the front and in the trenches.

We are quite sure that Mr. Macpherson did not mean to do injustice to any one, but owing, perhaps, to some confusion—possibly as to the significance of the phrase "civilian practitioners"—his words did a great deal less than justice to medical officers of the Special Reserve, Territorial Force, and those holding Temporary Commissions. An article on the Military Medical Services has been published in our columns each year since the beginning of the war, and the following condensed tables, founded on the figures there given, will serve to show how things stand. The figures have been collected from year to year with great care, and though there may be some errors, they must be so few as not materially to affect the conclusions to be drawn. In the columns referring to Territorials no attempt has been made to distinguish between those holding ordinary commissions in the R.A.M.C. (Territorial) from those holding commissions *à la suite* General Hospitals, who are, we believe, the only Territorial medical officers whose services are part-time. Lists of the officers so employed are not available, but it is known that many of those who hold commissions *à la suite* have been seconded from time to time for service with the forces abroad. The number of regular officers, including retired officers, employed in June, 1915, was 1,256, and of Territorial officers 2,621. Probably these numbers have not been materially altered since. The number of Special Reserve officers at the same date was 709, but the number is now no doubt much larger owing to the inclusion of men who have become qualified since that date. The number of temporary officers at that time was 2,697. It is in this category that the increase has been specially large, but we are unable to state actual figures as the *Army List* is not now available. In the circumstances, it is not possible to compare the relative losses each branch of the Royal Army Medical Corps (and Army Medical Service) has suffered or the honours it has received. It is, however, quite clear that the officers of the Special Reserve, Territorial Force, and those holding Temporary Commissions have paid a heavy toll in deaths in action or from wounds, and these figures may be taken as an index of the number of wounded. The tables do not include medical officers of the Overseas contingents or India, nor medical men who were serving as combatant officers.

B. = British. F. = Foreign.

With regard to civilian practitioners who are giving part-time services to auxiliary hospitals or other institutions we are not in a position to give any statistics; no list of them is available. They do not, we believe, receive commissions, but, so far as we are aware, very few have received any recognition of their services.

TETANUS IN HOME MILITARY HOSPITALS.

THE sixth analysis of cases of tetanus treated in home military hospitals, covering the period March to June, 1917, does not call for extended notice, since the figures under review were included in the analysis of a thousand cases of tetanus submitted by Surgeon-General Sir David Bruce in his presidential address to the Society of Tropical Medicine and Hygiene last autumn, which was summarized in the *JOURNAL* of February 23rd, 1918. The most noteworthy fact in the present analysis of 100 cases is that the death-rate was 29 per cent., as against 19 in the previous analysis, which was by far the lowest of the whole series. Sir David Bruce assumes from this rise in mortality that little more can be expected from the use of prophylactic and therapeutic antitetanic serum, and that it now remains with the surgeons to do the rest. "Surely," he says, "it is not beyond the ingenuity of man to devise some form of surgical treatment which will prevent the development of gas gangrene or tetanus in wounds." Eighty of the cases belonged to the generalized type of tetanus; of these 29 died, while the 20 localized cases all recovered. Thirteen cases of tetanus occurred after operative interference with the wound, and nine of them died—a death-rate of 72.7. It is noteworthy that in none of these was a prophylactic inoculation of antitetanic serum given before the operation, although the Tetanus Committee have advised that when operations are performed at the site of wounds, even if they are healed, a prophylactic injection of serum should invariably be given. Upon this Sir David Bruce makes the significant remark that at the present time and with our present knowledge it is a question as to whether a surgeon who neglected this prophylactic injection would not render himself liable to an action for malpractice. Lastly, he notes that, notwithstanding the Tetanus Committee's advice in favour of the intrathecal route and of the evidence from animal experiment, the intramuscular route is steadily becoming more popular. This, he thinks, is scarcely to be wondered at, since in the latest edition of a well-known and widely read textbook on medicine the intramuscular route is strongly recommended; its ease and freedom from danger are doubtless in its favour.

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Lost at Sea.

THE hospital ship *Glenart Castle* was torpedoed and sunk in the Bristol Channel, with great loss of life, at 4 a.m. on February 26th. She was outward bound, and had no patients on board, but carried a ship's complement of 120, 5 R.A.M.C. officers, 8 nurses, 2 chaplains, and 47 R.A.M.C. rank and file, out of whom only 25 of the crew and 4 of the R.A.M.C. rank and file were saved, 153 lives being lost. No officers were among the survivors. The following officers of the R.A.M.C. were lost: Lieut.-Colonel J. C. Furness, Captains A. E. Kelsey, L. Moysey, and G. W. Young, and Lieutenant J. A. Stainsby.

LIEUT.-COLONEL J. C. FURNESS, R.A.M.C.(S.R.).

Lieut.-Colonel James Collins Furness, R.A.M.C., was educated at Glasgow and at Charing Cross Hospital, and took the diploma of L.S.A. in 1901 and that of L.M.S.S.A. in 1907. Going into practice at Kids Grove, North Staffordshire, he was medical officer and public vaccinator to the Kids Grove and Goldenhill district of the Wolstanton and Burslem Union, surgeon to the police and to the St. John Ambulance Brigade, and county director of the Staffordshire Branch of the British Red Cross Society. He served with the 25th Field Hospital in the South African war, receiving the medal, and held the honorary rank of lieutenant in the army from March 1st, 1903. He attained the rank of major in the R.A.M.C. Special Reserve on June 18th, 1914, and had since been promoted to lieutenant-colonel.

CAPTAIN A. E. KELSEY, R.A.M.C.

Captain Arthur Edward Kelsey, R.A.M.C., was educated at Guy's Hospital and at Cambridge, where he graduated M.B. and B.C. in 1889. Entering the navy soon after, he attained the rank of fleet surgeon on November 11th, 1907, but had retired before the war, and settled at Reigate. He took a temporary commission as captain in the R.A.M.C. in July, 1917.

CAPTAIN L. MOYSEY, R.A.M.C.

Captain Lewis Moysey, R.A.M.C., was educated at St. George's Hospital and at Cambridge, where he graduated B.A., M.B., and B.C. in 1895, afterwards studying in Vienna. After acting as house-surgeon to the Paddington Green Children's Hospital, he went into practice at Radford, Nottingham. He joined the Notts and Derby Mounted Brigade Field Ambulance as lieutenant on October 22nd, 1914, and was promoted to captain after a year's service.

CAPTAIN G. W. YOUNG, R.A.M.C.

Captain Gerald William Young, R.A.M.C., was educated at Edinburgh, where he graduated M.B. and Ch.B. in 1903 and M.D. in 1907. He was serving as chief medical officer of the Antofagasta (Chile) and Bolivia Railway Company till he came home to join the R.A.M.C.

LIEUTENANT J. A. STAINSBY, R.A.M.C.

Lieutenant John Addison Stainsby, R.A.M.C., was educated at the London Hospital, and took the diplomas of M.R.C.S., L.R.C.P., and L.S.A. in 1894, after which he went into practice at Ecclesfield, Sheffield. He took a temporary commission in the R.A.M.C. in September, 1917.

HONOURS.

A SPECIAL Supplement to the *London Gazette*, issued on March 7th, contains the statements of the acts of "conspicuous gallantry and devotion to duty" for which the decorations announced in the *London Gazette* of October 18th, 1917, and published in the *BRITISH MEDICAL JOURNAL* of October 27th, 1917, p. 566, were conferred. The following medical officers are included in the list:

Bar to Military Cross.**Temporary Captain Oswald John Day, M.C., R.A.M.C.**

He organized stretcher-bearers, led them through enemy barrages, and effected the recovery of many wounded from close to the enemy's lines. (Military Cross gazetted June 18th, 1917.)

Temporary Captain Archibald Fullerton, M.C., R.A.M.C.

He dressed and evacuated thirty cases of another division and over fifty of his own battalion under most adverse conditions. His medical orderly was killed, leaving him single-handed, and one shell killed and wounded twelve of his stretcher-bearers. (Military Cross gazetted January 1st, 1917.)

Temporary Captain Noel John Hay Gavin, M.C., R.A.M.C.

He worked unceasingly for many hours at night dressing the wounded. When the medical officer sent to assist him was killed and the aid post was wrecked by shell fire, he continued his work of tending the wounded in the trenches and the open until relieved, although slightly wounded. He carried out his duties regardless of personal danger. (Military Cross gazetted June 4th, 1917.)

Temporary Captain Arthur John Rushton O'Brien, M.C., African Medical Service.

He repeatedly dressed the wounded under heavy artillery and machine-gun fire in the open, bringing out about 150 wounded with stretcher parties, until he himself was dangerously wounded whilst performing his duties close to the firing line. (M.C. gazetted February 13th, 1917.)

Temporary Captain David James Shirres Stephen, M.C., R.A.M.C.

He made a most daring reconnaissance in search of an aid post. Under very heavy fire he made arrangements for the removal of the

wounded and bringing up medical supplies. On another occasion he took over the evacuation of the wounded and reorganized the system of evacuation, displaying cool judgement and contempt of danger in searching for the wounded. He set a fine example to his men. (M.C. gazetted July 24th, 1915.)

Military Cross.**Captain John Alston, R.A.M.C.(S.R.).**

When in charge of stretcher-bearers he worked unceasingly for fifty-four hours, during the whole of which time he was under heavy shell fire, evacuating the wounded and clearing the field with great rapidity and skill. He declined to be relieved until he had seen the work through, setting a splendid example of cheerfulness and courage to all who were working with him.

Captain Robert Ringrove Gelston Atkins, M.B., R.A.M.C.(S.R.).

For seventy-two hours he worked continuously with his stretcher squads under very heavy artillery fire. He worked throughout a whole night between the various regimental aid posts and the advanced dressing station, organizing the evacuation of a large number of stretcher cases. He set a splendid example to all under him.

Temporary Captain Phillippe Bernard Belanger, R.A.M.C.

He moved about in the open, often having to jump from shell hole to shell hole, tending the wounded, regardless of the continuous machine-gun and shell fire. He was entirely responsible for the bringing in of many wounded men, and thereby saving their lives. He did not desist until he had the whole battalion sector cleared of wounded, and throughout he set a magnificent example to the stretcher-bearers who followed him.

Captain Thomas Herbert Bell, C.A.M.C.

During an attack he directed the work of the stretcher-bearers for forty-eight hours without rest. His energetic work and splendid courage under heavy shell fire were an example to all ranks, and were undoubtedly the means of saving many lives.

Captain William Somerset Birch, R.A.M.C.(S.R.).

For seventy-two hours he worked with the stretcher-bearers of his field ambulance, and collected the wounded under continuous fire. By his cheerfulness and disregard of danger he set a splendid example to all his bearers.

Temporary Captain Archibald Grainger Bisset, R.A.M.C.

During heavy shelling of his battalion, when it was impossible to establish a dressing station, he went up and down the line himself attending to the men as they fell. Whenever a shell burst in the vicinity he at once hastened to the spot and did not leave the shelled area after his battalion had moved off until every case had been evacuated. He has shown the greatest gallantry and coolness at all times, notably on one occasion when, although badly gassed and unable to stand, he continued to attend to the wounded until he collapsed.

Captain Arthur Bloom, R.A.M.C.

Several casualties were caused by shell fire at a battery position. He at once went 300 yards through a heavy barrage to the position, being blown up by an exploding shell on the way. He immediately attended to two wounded men, and then, while the battery was still being shelled, went round the position and attended to other wounded men. He displayed great courage, and his prompt action was of very great value.

Temporary Captain Oswald Vincent Burrows, R.A.M.C.

For forty hours he worked unceasingly succouring the wounded, about 300 of whom passed through his hands during that period.

Temporary Captain Charles Kingsley Carroll, R.A.M.C.

He carried on his work during an attack in one of the most exposed situations regardless of his own safety. His energy and devotion to duty saved many lives.

Captain John Philip Selby Cathcart, C.A.M.C.

During an attack he displayed masterly ability and the greatest devotion in attending to the wounded, and on one occasion, when stretchers were urgently required in the front line, personally carried out four from his dressing station—a distance of 1,000 yards—under the heaviest shell fire. This very gallant act enabled several wounded men to be rescued. His work has at all times been characterized by fearless zeal and untiring energy.

Temporary Captain John Percival Charles, R.A.M.C.

He worked untiringly evacuating the wounded during the attack, continually dressing the wounded in shell holes under very heavy fire until he was wounded. He set a magnificent example of fearlessness and devotion to duty.

Temporary Captain Andrew Tocher Cunningham, R.A.M.C.

During a raid on the enemy's lines he worked continually throughout an intense bombardment, attending to the wounded at the aid post until they had all been attended to and evacuated. He showed great courage and devotion to duty.

Temporary Captain Lionel Montrose Dawson, R.A.M.C.

While acting as officer in charge of bearers, he searched and cleared the line during the advance and during a counter attack. He kept the regimental aid posts clear under trying circumstances, frequently going through a hostile barrage. He remained at his post for twenty-four hours without rest under very heavy fire.

Temporary Captain Harold John de Brent, R.A.M.C.

He went about in a most fearless manner under heavy shell and machine-gun fire, collecting the wounded, dressing them in the open and cheering them up. He remained in the most advanced position, almost surrounded by the enemy, until he had succeeded in attending to and clearing all the wounded. He took on the work of two other medical officers who were wounded and remained at his post for a further five days. His conduct was magnificent throughout.

Temporary Captain Carl Keating Graeme Dick, R.A.M.C.

He rescued three men from a dug-out which had been blown in and brought them to his aid post. His aid post was under shell fire, but he went on working, and when his aid post was full he continued work outside utterly regardless of his own safety. It was largely owing to his gallant conduct that so many wounded were safely evacuated.

Temporary Captain James Dickson, R.A.M.C.

When at his aid post a shell exploded in the doorway, killing and wounding fourteen persons in the room where he was. Although very badly shaken he continued his work until relieved twenty-four hours later.

Captain Franklin Fletcher Dunham, C.A.M.C.

He remained at his dressing station for four days, steadily performing his duties although exposed all the time to shell fire and gas attacks. Although severely gassed on the second day, he continued to carry on until he collapsed, having set a splendid example of self-sacrifice and devotion to duty.

Lieutenant Louis du Vergé, R.A.M.C.

During an action he constantly dressed the wounded in the open under heavy shell fire, and showed complete disregard for his own safety.

Temporary Captain Henry Hawes Elliot, R.A.M.C.

During several days' operations he was out under very heavy fire finding wounded men, attending to them, and helping them back to the aid post, and, though wounded, continued at duty. When his aid post received several direct hits, he succeeded in evacuating all the wounded to a safer position. He set a fine example to his stretcher-bearers.

Temporary Captain Henry Vincent Forster, R.A.M.C.

When a counter-attack seemed imminent, he rallied every available bearer under heavy fire, and evacuated all the wounded through a heavy barrage. He set a magnificent example to all during several days' operations.

Temporary Captain Cosmo William Fowler, R.A.M.C.

He worked throughout the day during an attack, showing complete disregard of danger. On two occasions he went out in front of the line and brought in wounded who would otherwise have fallen into the hands of the enemy.

Temporary Captain James Harcourt Cecil Gatchell, R.A.M.C.

He worked with great zeal for many hours in the open under heavy shell fire. He frequently dressed wounded men on the spot who they were hit, and when he was wounded he refused to leave his post until ordered to do so by his commanding officer. His contempt of danger and devotion to duty were an example to all ranks.

Temporary Lieutenant John Alan Campbell Greene, R.A.M.C.

When an advanced dressing station was shelled with 8-inch shells, he at once went to the spot and began to dig out men who were buried. Though the shelling continued he did not desist until satisfied that the men were dead. He then assisted in clearing the entrance to the dressing station and attended to the wounded within. He showed an entire disregard of personal safety in his efforts to save life.

Captain David Alexander Ross Haddon, R.A.M.C. (T.F.).

The dressing station was very heavily shelled, and he immediately ran to the centre of it, where he attended to all the wounded, and assisted in the evacuation of stretcher cases. He carried out operations in a hut which was continually under shell fire. He set a magnificent example to all.

Captain John Livingston Hamilton, R.A.M.C.

For conspicuous gallantry and devotion to duty when in command of a stretcher-bearer subdivision during a raid on the enemy's lines. During an intense bombardment and when he himself was twice wounded, he continued to dress the wounded throughout the night until they had all been evacuated. He set a magnificent example throughout the action.

Temporary Captain David Cochrane Hanson, R.A.M.C.

Regardless of all danger he attended to the wounded in the open under the heaviest shell fire, and, though knocked over several times by the explosion of shells, he continued to direct the work, and succeeded in getting the wounded out of the barrage zone. His gallant conduct was undoubtedly the means of saving many lives.

Temporary Captain Arthur Raudell Jackson, R.A.M.C.

He was ceaseless in his efforts to get in casualties, repeatedly going forward through enemy barrages to the advanced posts. He worked in the open throughout the day, and set a splendid example to his stretcher-bearers.

Captain Charles Llewellyn Lander, R.A.M.C.

He worked at an advanced dressing station on the line of the enemy barrage, and afterwards passed through the barrage to another dressing station, where he worked for a day and a half under continuous shell fire. He showed great courage and disregard of danger.

Captain Harold Dnnmore Lane, R.A.M.C.

During a daylight raid on the enemy's trenches he established his aid post in the front-line trench, and worked there for many hours under heavy artillery fire. He attended to the seriously wounded cases in the open, and was instrumental in bringing in all the wounded from No Man's Land and getting them successfully away.

Captain Peter MacCallum, R.A.M.C. (S.R.).

He was in charge of the evacuation of the wounded from an advanced position, and worked in the open under very heavy fire for four successive days and nights, organizing stretcher squads and directing the removal of the wounded. He was the means of finding several severely wounded men lying in shell holes and bringing them to safety under heavy fire. His splendid example and utter disregard of danger were largely responsible for the success of the evacuation.

Captain Albert Edward Peel McConnell, R.A.M.C.

When in charge of the evacuation of the wounded, though heavily shelled, he kept his line perfectly clear. He superintended the evacuation personally, working for forty-five hours without ceasing under the most difficult and dangerous conditions, and by his example encouraged the men under him in every possible way. Later, he took two stretcher squads to the relief of batteries which were being heavily shelled.

Captain Emmet Andrew McCusker, C.A.M.C.

Under continuous and heavy shell fire, during which his dressing station was several times hit, he not only carried out his duties as medical officer with coolness and energy, but on several occasions carried in wounded from the front when stretcher-bearers were not available. He also rescued, under a heavy shelling, a number of wounded men who were buried in a cellar. He set a splendid example to all.

Temporary Captain Donald John MacDougall, R.A.M.C.

During the seventy hours the battalion was in the line he displayed great courage and fearlessness, dealing with a large number of wounded without assistance when all his orderlies had become casualties and his stores had been destroyed by shell fire.

Temporary Captain Douglas Charles Murray Page, R.A.M.C.

For conspicuous gallantry and devotion to duty in going through a heavy barrage in search of two wounded officers, about five hundred yards across the open. He dressed their wounds in the open by the light of the gun flashes. Hearing that the M.O. of the relieving unit had been wounded, he obtained permission to remain with the incoming unit.

Captain Arthur Allan Parker, C.A.M.C.

He directed the clearing of the wounded from his regimental aid posts, being without rest for thirty-six hours, during all of which time he was exposed to more or less heavy shelling. He set a splendid example to his men.

Captain William Barry Postlethwaite, R.A.M.C. (S.R.).

He set a splendid example of untiring energy and contempt of danger to his stretcher-bearers throughout the operations, repeatedly leaving his aid post under heavy fire to attend to the wounded. He organized bearer parties, and went forward with them into No Man's Land and brought in a large number of wounded.

Captain James Wilfrid George Hewat Riddell, R.A.M.C.

While the battalion was assembling for the attack he attended to a large number of wounded on the spot. He was shelled out of his aid post, but during the whole of the day of the attack he attended to the wounded under heavy fire, and at night, when all the cases at the aid post had been attended to, he went out and dressed cases in No Man's Land and guided stretcher parties to the wounded lying out in front.

Captain Stanley Graham Ross, C.A.M.C.

During an attack he directed the evacuation of the wounded for forty-eight hours continuously, and repeatedly aided the wounded under very heavy shell fire. The example which he set to all ranks, and his unbounded energy, was no doubt the means of saving many lives.

Temporary Captain William Russell, R.A.M.C.

When his regimental aid post was blown in and most of the personnel and wounded killed, he went up to it through a heavy barrage and succeeded in evacuating all the survivors. On six occasions during the day he guided parties of bearers and brought back wounded, always in the open under heavy fire.

Captain James Bethune Scott, R.A.M.C. (S.R.).

A camp was heavily shelled and many casualties were caused. He showed great gallantry in going to the assistance of the wounded on three separate occasions in spite of heavy fire. By his coolness he not only saved many lives, but gave great confidence and encouragement to the men around him.

Captain William Henry Scott, C.A.M.C.

During a heavy hostile gas-shell bombardment his dressing station, which was in a cellar, became full of "mustard gas." He and his whole staff were gassed, but with the greatest courage and devotion he remained in the cellar after all his assistants had been evacuated, and attended to three wounded men who could not be left. No praise is too great for the gallant manner in which he discharged his duties under these dangerous conditions.

Temporary Captain Edward Seguir Sowerby, R.A.M.C.

He guided parties of bearers, bringing back wounded in the open over most difficult ground and under heavy fire. On one occasion he led a party through a heavy barrage and succeeded in collecting many wounded from close to the enemy's line.

Temporary Captain William Turner, R.A.M.C.

He had on two occasions to change his regimental post, on account of its being destroyed by shell fire, but continued to dress the wounded of three battalions throughout the day in the open under heavy fire.

Lieutenant Samuel Vidot, R.A.M.C. (S.R.).

He carried on his work continually under heavy shell fire throughout the operations, and stayed behind after the battalion was relieved to attend to the wounded. He had previously entered a dug-out which was full of fumes and rescued a wounded officer.

Temporary Captain John Alexander Vlasto, R.A.M.C.

He attended to over one hundred cases of wounded under extremely heavy shell and rifle fire. During a gas and smoke cloud he worked ceaselessly in the firing line, attending to men gassed and wounded. His courage and total disregard for his personal safety were a splendid example to all around him, and were the means of saving many lives.

Captain James Walter Woodley, C.A.M.C.

On being informed that there were some wounded lying unattended in an advanced and exposed position he at once went to the spot through a heavy barrage and attended to them. After dressing all the wounded he returned to his post and arranged for stretcher-bearers to take them to the dressing station. He went about continuously during the operations, attending to the wounded under most intense fire with complete disregard of danger.

MENTIONED IN DISPATCHES.

The following medical officers are among those mentioned by Major-General A. R. Hoskins, late Commanding-in-Chief, East Africa Force, in a dispatch dated May 30th, 1917:

Royal Navy: Surgeon (acting Staff Surgeon) C. G. Sprague, R.N.

Staff: Major R. T. Brown, D.S.O., R.A.M.C.

Medical Services: Lieut.-Colonel S. E. Frall, I.M.S. Majors (temporary Lieut.-Colonel) A. MacMunn, R.A.M.C.; C. G. Seymour, I.M.S. Majors: A. Cameron, C. E. Southon, G. G. Hirst, and W. S. McGillivray, I.M.S.; H. B. Owen and J. H. Reford, Uganda Medical Service; D. M. Tomory and P. St. J. Wilkinson, S.A.M.C. Temporary Majors: R. T. Meadows, D.S.O., R.A.M.C.; W. Owen-Fritchard, E.A.M.S.; A. D. J. D. Williams, E.A.M.S. Captains (acting Majors): J. Evans,

S.A.M.C.; W. A. MacLennan, R.A.M.C.(S.R.). Captains: R. S. Armour, G. B. Fleming, J. D. Kidd, W. Mitchell, and B. Varvill, R.A.M.C.; J. J. D. La Zonche, R.A.M.C.(S.R.); G. T. Burke, M. L. C. Irving, W. M. Lupton, and M. J. Roche, I.M.S.; E. G. Smith, S.A.M.C. Temporary Captains: I. B. V. L. Dale and C. J. Wilson, E.A.M.S.; A. J. R. O'Brien and T. R. Sandeman, W.A.M.S.; A. M. Webber, R.A.M.C. Lieutenant G. Covell, I.M.S.

In a dispatch dated May 15th, 1917, from Brigadier General E. Northey, commanding Nyasaland Rhodesian Force, the names of Temporary Lieut.-Colonel H. H. Y. Pearsey, Director of Medical Services, and Temporary Captain A. G. Eldred are mentioned.

Lieut.-General Sir J. Van Deventer, Commanding-in-Chief, East Africa Force, in a dispatch dated October 11th, 1917, mentions the following for meritorious service in the field:

Staff: Colonel (temp. Surgeon-General) G. D. Hunter, C.B., C.M.G., D.S.O., A.M.S.; Lieut.-Colonel (temp. Colonel) G. W. Tate, D.S.O., R.A.M.C.; Lieut.-Colonel C. J. O'Gorman, D.S.O., R.A.M.C.; Captain R. S. Kennedy, M.C., I.M.S.

Royal Army Medical Corps: Major H. Hemsted; Captains R. P. Cornmack, P. E. Lander, E. S. Wallis (S.R.); Temporary Captains D. McIntyre, A. McP. Warner; Temporary Quartermaster and honorary Lieutenant E. J. Harris.

East African Medical Service: Captains A. R. Cook (Uganda Medical Service), J. O. Shircore.

South African Medical Corps: Lieut.-Colonel T. Smythe; Major (acting Lieut.-Colonel) W. Gilbert; Captains (temporary Majors) F. S. Jones, W. D. Miller; Captains A. P. M. Anderson, A. McW. Green; Temporary Captain A. F. H. Rabagliati.

Temporary Major (acting Lieut.-Colonel) T. M. R. Leonard, W.A.M.S., Nigerian Contingent; Surgeon-Captain J. A. Chisholm, Northern Rhodesia Medical Service.

Indian Medical Service: Captain R. M. Easton and E. H. V. Hodge; Temporary Lieutenant S. A. Paymaster. Eight assistant and subassistant surgeons of the I.S.M.D. are also mentioned.

FOREIGN DECORATIONS.

The King of the Belgians has conferred the Croix de Guerre upon the following officers of the A.M.S. and R.A.M.C. in recognition of services rendered during the course of the campaign: Lieut.-General Sir Arthur T. Sloggett, K.C.B., K.C.M.G., K.C.V.O., Surgeon-General R. Porter, C.B., Brevet-Colonel S. L. Cummins, C.M.G., Lieut.-Colonel (temporary Colonel) J. D. Alexander, D.S.O., Lieut.-Colonel A. Chopping, C.M.G., Major H. Stedman, Captain T. F. Corkill, temporary Captains Myer Coplaus, D.S.O., and J. H. H. Pearson.

Lieutenant-Colonel (temporary Colonel) Henry N. Dunn, D.S.O., R.A.M.C., has been appointed C.M.G. for services rendered in connexion with military operations in the field.

The D.S.O. has been conferred upon Major (acting Lieut.-Colonel) Henry Fulton, R.A.M.C., for distinguished service in the field.

Major E. S. Forde, R.A.M.C., has been promoted to brevet lieutenant-colonel for valuable services rendered in connexion with the war.

Surgeon Probationers W. P. Warner and I. M. Thompson, R.N.V.R., have been mentioned in dispatches for services in destroyer and torpedo-boat flotillas, and the former is awarded the D.S.C.

England and Wales.

A SCHEME FOR A STATE MEDICAL SERVICE.

A MEETING was held on February 28th of medical practitioners resident in the area of the Brighton Division, with Dr. Hobhouse in the chair. After a proposition to the effect that any extension of State medical service is undesirable had been lost by a small majority, approval was given to a scheme submitted by a special committee appointed in June, 1917, to consider and report on the future of the medical profession under a proposed Ministry of Health. It was resolved to submit this committee's report to the Council of the British Medical Association, together with a copy of the resolution approving the scheme contained therein. The proposal, in the broadest outline, is for the establishment of a National Health Office, combining the health functions of the Local Government Board and of the Insurance Commission, a chain of administration being established downwards from the central office, consisting of a staff of medical men on the preventive and clinical sides responsible to the Minister of National Health, with an executive medical staff in each area. The object of the scheme is to establish a whole-time salaried State medical service acceptable to the medical profession, with provision for hospital treatment, for a service of consultants and specialists, and for central laboratories. The

financial basis of the service would be an extension of the existing insurance for medical benefit to all classes of the community. The scheme aims at the protection of existing personal interests, the preservation of freedom of choice for doctor and patient, the right to private practice of executive medical officers, and such conditions of service and pay as will attract to the medical profession the best type of person.

DIAGNOSIS AND TREATMENT OF VENEREAL DISEASES.

Dr. E. W. Hope has recently published a memorandum on the scheme now in operation in the city of Liverpool. It will be revised and readjusted at the end of an experimental period of twelve months. A similar scheme has been established for Lancashire, and the County Medical Officer, Dr. J. J. Butterworth, has recently issued information with regard to it. In both documents the addresses of the various centres or clinics and the hours of attendance are set out. The Venereal Disease Act, 1917, came into operation in Liverpool on March 1st. The perennial difficulty in persuading patients to continue treatment until they are cured has not yet been surmounted. During the quarter ending September 30th at one of the large hospitals in the city it is recorded that fully 50 per cent. of the patients suffering from syphilis and over 30 per cent. of those suffering from gonorrhoea failed to complete the course of treatment. The same trouble arises among the prisoners infected with venereal diseases and under short sentences of detention. It would seem, therefore, eminently desirable that some form of compulsion should be adopted, and the medical officer of health sets out the Venereal Diseases Act, 1916, passed by the Legislature of Victoria, Australia, that would overcome irregularity of attendance. The Local Government Board is urged to adopt some restrictive measures with respect to prisoners whose treatment is not completed at the expiration of sentence. It is suggested that such persons should, on the orders of the visiting justices, be taken into a suitable hospital and detained there for treatment until cure is completed.

CENTRAL CONTROL BOARD (LIQUOR TRAFFIC).

Dr. Henry Barnes, O.B.E. (Carlisle), writes: In continuation of my previous communications regarding the work of the Central Control Board (Liquor Traffic) in Carlisle I send some notes on the annual report of the general manager of the Board in the Carlisle and district directly controlled area during the year 1917.

The total area comprises about 320 square miles, with a population of about 115,000, and contained 339 licensed premises at the beginning of July, 1916. The work of suppressing redundant licences has been continued. When the Board commenced its operations in 1916 there were in the city of Carlisle 119 licences. These were at once reduced to 94, and last year 24 more licences were suppressed. As far as possible all houses have been closed which from their position or structure were undesirable. In the country district surrounding the city there was a corresponding reduction of redundant licences.

Early in the year a Spiritless Saturday Order was instituted and has had a most beneficial effect. On the seven Saturdays preceding the issue of the Order there were 45 apprehensions for drunkenness. On the same number of Saturdays succeeding the same date there were 7 apprehensions, all on St. Patrick's Day (reflecting the nationality of a large number of navvies then living in the city.) Previous to the issue of the Order Saturday had the greatest number of "drunks" of any day in the week, but now it has the fewest, and this is the more remarkable as it is our market day, on which large numbers of residents from the surrounding districts come to the city for their weekly shopping. Some inconvenience has resulted, but on the whole a balance of advantage is claimed. Another restriction authorized by the Board relates to the "off" sales of spirits. Previously all fully licensed houses could sell spirits for consumption "off" the premises. The Board selected eighteen houses in different parts of the city to have the exclusive right of "off" sales. This number has since been reduced to fifteen.

A very pernicious practice has been stamped out. Among certain classes it was customary to order spirits and beer at the same time. The spirits were consumed neat and washed down with beer. This was a widespread custom and led to much drunkenness. A definite instruction was given to the Board's managers that no

order was to be received from any customer for beer and spirits to be served together.

Much criticism on the Board's work has been made, alleging that the decrease in the convictions for drunkenness has not been due to any of the Board's regulations, but has been caused by the departure of the constructional workers. This theory is in contradiction to the facts. Sir Edward Pearson, the constructional manager of H.M. factory at Gretna, says that the number of workmen employed in construction work was practically the same at the end of 1916 as at the end of June in that year, when the Board first began its work. The following table, showing the number of convictions in each quarter for the past three years, shows what an enormous reduction has taken place:

	First Quarter.	Second Quarter.	Third Quarter.	Fourth Quarter.	Total.
1915	38	34	35	170	277
1916'	213	351	199	190	953
1917	164	65	48	43	320
Decrease 1917 on 1916	49	285	151	127	633

There are four chief factors for this reduction, of which the three last are entirely due to the action of the Board in taking control of the liquor traffic in Carlisle.

1. The gradual disappearance during the first half of 1917 of the navvies and their replacement in part by artisans and operatives at the Gretna factory.

2. The closing of redundant houses.

3. The institution of spiritless Saturdays.

4. The strict supervision exercised by the Board's managers.

Notwithstanding the withdrawal from Carlisle of constructional workers, the Chief Constable estimates that there is still an additional population of 13,000 residing in and around Carlisle. The improvement in the condition of the streets, especially at night, deserves notice, and impresses itself upon residents and visitors alike. Although the streets are unduly crowded, a drunken person is exceptional.

The policy of the Board in their constructive work has been to cater for the refreshment of all sections of the community. Seven "food taverns" have been completed. The Gretna Tavern proved a success from the first, and has continued to be most popular. The takings for food alone average about 60 per cent. All the other taverns are doing well, and at one of them, in an industrial part of the city, some sixty or seventy persons take their daily dinner. At several of them arrangements have been made for the "off" sales of food, and the average number of purchases each day exceeds 800. A sustained effort has been made to push the sale of food in the ordinary public-house. About a score of houses were selected for the attempt and were kept open on weekdays from 10 a.m. to 3 p.m., with an interval of half an hour at 2.30 p.m. for ventilation and cleaning, and on Sundays from 12 to 2 and 4 to 6 (lately changed to 7 to 9). Owing to food shortage, the attempt under war conditions to resuscitate the functions of a victualling house of the past has been rather a failure. The average worker prefers to take his meals at home and his intoxicants in the public-house, where he can meet his friends.

In June last Lord D'Abernon stated that so far as results are available, the profit and loss account shows a balance of about 15 per cent. on the capital charges, after meeting all the trade charges, but as the total capital expenditure has not been ascertained, a definite statement cannot yet be made. Provided, however, that the total does not exceed the amount anticipated, there is reason to believe that, after making all proper deductions, the rate of profit earned will prove to be on the scale foreshadowed by Lord D'Abernon.

To those interested in this question I would recommend two books, in one of which the question of State purchase is fully considered—namely, *The Control of the Drink Trade*, by Henry Carter, a member of the Control Board (Longmans, 7s. 6d.), and the other, the small volume on *Alcohol: its Action on the Human Organism*, issued by a committee appointed by the Board. As was pointed out in the JOURNAL on February 23rd (p. 238), it gives a concise statement of the present state of knowledge on the action of alcohol on the human body.

VITAL STATISTICS OF 1916.

The report of the Registrar-General for England and Wales for 1916 contains the final corrected figures. The marriage-rate was 14.9 per 1,000, being 4.5 below the phenomenally high rate in the preceding year, and 0.5 below the average for the ten years 1905-14, which were unaffected by war conditions. The provisional figures for the first two quarters of 1917 indicate a further fall. The birth-rate was 20.9 per 1,000, being the lowest on record, although the provisional figure for 1917 shows a still further decline to 17.7. The rate for 1916 was 4.6 below the average for the ten years 1905-14, and 1.0 below the rate in 1915. Speaking of the statistics down to the end of 1916, it is said that on the whole the reduction of natality in this country which had accompanied the war, amounting to about 12 per cent. in 1916 as compared with 1914, was less than might have been expected, and compared very favourably with the experience of other belligerent countries. The civilian death-rate in 1916 was 14.4, which is the same as the provisional figure for 1917. It is 1.3 below the rate in 1915, and 0.1 below the average rate for the ten years 1905-14; although the rate in 1916 was higher than in some of the years immediately preceding the war, reasons are given for regarding it as representing a mortality approximately equal to the lowest hitherto recorded, if due allowance be made for the effect of enlistment upon the population. The mortality of young children was lower in 1916 than in any previous year; it was 91 per 1,000, or 19 below the rate of the preceding year, and 22 below the average for the ten years 1906-15. The provisional figure for 1917 is higher—97.

Correspondence.

LONGEVITY.

SIR,—Cicero in the Cato Major sets forth as the ideal of advanced life the gradual decline of the physical energies compensated by a steady increase in intellectual vigour. But this latter condition, he shows, can alone be brought about by the ceaseless cultivation of the powers of the mind. Milo weeping in senile decay over his withered arms with no intellectual attainment to compensate him for his loss of muscular strength, Cicero places in striking contrast to Cato who, with his cultivated brain, takes up the study of Greek literature in old age with an eagerness which, we are told, was like the desire of quenching a long thirst—*quasi diuternam sitim explere cupiens*—a receptivity of mind indeed enviable at any time of life.

Sir Herman Weber has written an able and lucid article (p. 228), truly a wonderful feat at 95 years, but one could have wished that mental culture, which Sir Herman merely mentions, had been equally insisted on with muscular exercise. Which of these two activities is of the greater benefit in old age it would be difficult to prove. A fact, however, which points clearly to the life-prolonging tendencies of mental activity is that many business and professional men continue their work well into advanced life with little abated energy and sometimes at high mental pressure, but on retirement rapidly decline in brain power and physical vigour, although there has been little, if any, cessation of muscular exercise. Mental activity in old age appears to stimulate and sustain all the vital processes, but rarely exists to any great extent at this period apart from enthusiasm—a mainspring which probably accounts for the extraordinary longevity, energy, and skill in old age of many of the Royal Academicians, the perfection of whose works executed late in life frequently rivals that of their earlier years.—I am, etc.,

Liverpool, Feb. 23rd

WILLIAM BRANWELL.

SUPPLY OF ARSENOBENZOL DRUGS TO GENERAL PRACTITIONERS.

SIR,—The objection to the suggestion of Dr. A. Knyvett Gordon appears to me to be that the intramuscular injection of these drugs is usually attended by so much after-pain that it is difficult to persuade private patients to have

a second dose. The paper of Harrison, White, and Mills¹ was based upon their experience in military hospitals, where the patients are under discipline, and I think if they had been dealing with private patients they would have come to a different conclusion.

I have given intramuscular injections to five private patients of my own, and all but one complained severely of the after-pain, which they stated prevented them from working for a week or more. The one who did not complain was suffering from incipient locomotor ataxia, and the nervous lesion probably accounted for the absence of pain. It may be objected, perhaps, that I am incompetent to form an opinion, having had such a small experience, and that my technique was faulty; but a general practitioner is obliged to form his opinion on a comparatively small number of cases, and in giving the injections I was careful to follow closely the instructions given by the authors of the paper I have referred to.

I have given many intravenous injections of these drugs, and have yet to experience any trouble with them. The technique is easily acquired, and the patient experiences no pain or unpleasantness.

It is very frequently difficult to persuade patients suffering from syphilis to undergo a sufficiently long course of treatment to obtain good results, and if a method is adopted that gives them pain and keeps them from work, I am sure that very few cases will be efficiently treated.—I am, etc.,

London, W., March 10th.

J. A. BUTLER, M.D.

THE TREATMENT OF WOUNDS BY FLAVINE.

SIR,—In the BRITISH MEDICAL JOURNAL of March 9th Dr. C. H. Browning comments on my observations which appeared in your issue of March 2nd, and suggests that my results were due to the fact that I employed gauze "wrung out in 1 in 1,000 solution" instead of "gauze soaked in flavine solution."

If I understand Dr. Browning's suggestion it is that I did not employ a sufficient amount of flavine solution in the packs to obtain good results. The distinction in terms made by him is open clinically to fallacies into which I need not enter here, and I am not prepared to admit that there is any essential difference between them in practice, but I will state now that in my investigations the gauze packs were "soaked in," saturated with, and "wrung out in" flavine solution in varying degrees in different cases without modifying my results in any way in regard to the control of sepsis.—I am, etc.,

WILLIAM PEARSON,
Major R.A.M.C.

Chichester, March 11th.

THE DISAPPEARANCE OF ABNORMAL HEART SOUNDS.

SIR,—Dr. Gordon's communication with regard to changing heart sounds calls to mind the very frequent similar experience amongst children in a tuberculosis dispensary. Well-marked sounds may be heard at one visit, and at the next, after an interval of a month or two, careful listening fails to find them. Mitral, pulmonary, or aortic areas may be the best spots for hearing them in particular instances, but all are influenced by respiration.

Since these abnormal sounds are accompanied by glandular enlargement—visible or definitely to be inferred from other signs and symptoms—as, for example, in hilus tuberculosis, it is reasonable to conclude that shrinkage or disappearance of these nodes must be the cause of their vanishing. They disappear more surely when the von Pirquet test is negative. Should thyroid enlargement be present these abnormal sounds are usually more pronounced, especially in the neighbourhood of the right sterno-clavicular articulation.

Sputum examination mostly shows diplococcal infection, and the patients generally and quickly do well with rest in a well-ventilated hospital ward.—I am, etc.,

Newport, Mon., March 4th.

J. LEWIS THOMAS.

GONORRHOEA COMPLICATED BY SYPHILIS.

SIR,—With reference to Captain Lumb's article on gonorrhoeal complication in patients undergoing anti-syphilitic treatment (p. 285), I should suggest that the

arsenobenzol compound is more likely to be the cause than the mercury. It is an almost universal rule that patients complain of increased urethral discharge on the day after receiving an injection of arsenobenzol. I am inclined to think that the arsenic either irritates the urethral mucous membrane, causing an increased discharge, or stirs the gonococcus into activity, possibly by lowering the resistance of the mucous membrane. Surely mercury is now combined with arsenobenzol because it was found that cases were apt to relapse in the early days of salvarsan alone.—I am, etc.,

Shefford Military Hospital,
St. Albans, March 12th.

H. E. GIBSON,
Captain R.A.M.C. (T.F.)

THE PAY OF TERRITORIAL R.A.M.C. OFFICERS.

SIR,—The letter of J. W. L. Spence in your issue of February 16th deserves the widest publicity and immediate action by the authorities. The practice of treating a territorial unit as a parochial or "family" formation with promotion entirely within the unit should have ceased at least as soon as a unit embarked for expeditionary service. Its perpetuation has been utterly unjust. Officers who joined the Territorial Force in its early days and came forward most patriotically from important appointments for expeditionary service found themselves serving under very junior officers with many years' less commissioned service. Many men taken to complete establishments have been holding senior appointments and drawing the corresponding pay for years. These men also participate unduly in the decorations which almost go with certain appointments as a matter of course. There is also a grievance against officers who declined to accept foreign service at the beginning, and as a "reward" were given senior appointments at home. This matter is really becoming a serious problem for officers who have been suffering financially through being on service for years, and the duration lingers beyond anticipation.—I am, etc.,

March 7th.

JUSTICE.

The Services.

PAY AND PROMOTION OF SPECIAL RESERVE MEDICAL OFFICERS.

IN the JOURNAL of February 2nd, p. 164, and again in the SUPPLEMENT of February 9th, p. 17, attention was drawn to the action of the Army Council in negating one of the recommendations of the Departmental Committee on the promotion and pay of officers of the R.A.M.C., Special Reserve and Territorial Force. The Committee, of which Lord Burnham was chairman at the time this report was made, recommended that

Officers of the R.A.M.C., Territorial Force, and Special Reserve who joined before the war should be put on a level with temporarily commissioned contract officers as regards pay, allowances and gratuities, where they would gain thereby. The refusal of the Army Council to accept this recommendation of the Committee was under the consideration of the Naval and Military Committee of the Association at its meeting last month, and further representations will no doubt be made. We have received a letter from a correspondent who considers that the Army Council's refusal to accept the recommendation of the Burnham Committee is particularly unjust to officers of the Special Reserve, and peculiarly ungracious, inasmuch as they were all subject to the general service obligation from the first, so that many of them were in the retreat from Mons. The Departmental Committee pointed out that

Officers of the Special Reserve are promoted up to the rank of major by length of service under the same conditions as apply to regular officers of the corps [that is to say, on the completion of twelve years' total service]. . . . There is, however, no establishment of lieutenant-colonels, and, consequently, no prospect of officers receiving substantive promotion to that rank. The Special Reserve of officers of this corps was in fact designed primarily to provide officers of junior rank to supplement the regular officers of the corps. But the expanding medical needs of the present war have led to the creation of a large number of lieutenant-colonels' appointments. Some of these are held by Special Reserve majors (with acting rank), and the Committee are of opinion that there is no longer any ground for the restriction of substantive promotion to the rank of major.

Consequently it recommended that majors of the Special Reserve should be linked with majors of the regular

¹ BRITISH MEDICAL JOURNAL, May 5th, 1917.

R.A.M.C., and be eligible for promotion to substantive rank. It is to be noted that the pay of a captain R.A.M.C. (Regular) is 15s. 6d. a day, but after seven years' full pay service in that rank it rises to 17s. Our correspondent's suggestions are as follows:

1. Those of the Special Reserve who were already captains on the outbreak of war (about thirty in all) should be promoted to temporary major forthwith (with pay and allowances).
2. Captains should, after five years' service, draw the 1s. 6d. extra per day allowed to Regular R.A.M.C. captains.
3. The increase of pay recently granted to combatant officers and the same scale of allowances for children should be made applicable to S.R. and Territorial officers.
4. All promotions suggested above should date back to April, 1917, as was promised at the time.

R.A.M.C. PROMOTION.

A CORRESPONDENT with the British Expeditionary Force informs us that a recent general routine order lays down that an officer of the R.A.M.C. (Regular, Special Reserve, Territorial Force, or temporary) below the rank of major who holds an appointment expressly assigned to a major in war establishments may be granted the acting rank of major when there is an actual vacancy or when a vacancy occurs owing to the absence of a major by reason of wounds or sickness. Temporarily commissioned officers also granted such acting rank will receive the pay and allowances of a major, and special provision is made for the adjustment of their gratuity.

With reference to the second report of the Departmental Committee on the promotion of R.A.M.C. officers (BRITISH MEDICAL JOURNAL, February 2nd, p. 164), another correspondent inquires whether the second part of the recommendation that a general list for promotion should be introduced "for the Territorial Force field ambulance and regimental medical officers" may be taken as applying to all regimental officers. The report makes it clear that Territorial officers only are referred to. Our correspondent maintains that a general list should be introduced for all regimental medical officers irrespective of the branch of the corps to which they belong.

Obituary.

PROFESSOR JOSEPH PRICE REMINGTON, Chairman of the Committee of Revision of the United States *Pharmacopoeia*, died at Philadelphia on January 1st, aged 70. He had been professor of pharmacy in the Philadelphia College of Pharmacy since 1874, a member of the Committee of Revision since 1880, and its chairman since 1901. He was the president of the first International Pharmaceutical Congress held at Brussels in 1893, and represented the United States at all the congresses held since. He was the author of *Remington's Practice of Pharmacy*, the first edition of which appeared in 1886, and he was editor of the *United States Dispensatory* since 1883.

LIEUT.-COLONEL ALEXANDER LEONARD DUKE, Bengal Medical Service, died of pneumonia at Quetta on February 27th, aged 51. He was born on October 12th, 1866, and educated at Aberdeen University, where he graduated M.B. and C.M. in 1888. Twenty years later, in 1908, he took the degree of B.Sc. in Public Health at Edinburgh. He entered the I.M.S. on September 30th, 1899, became major on September 30th, 1901, and lieutenant-colonel on September 30th, 1909. After six years spent in military employ he joined the Indian Political Department as surgeon to the British Agency at Meshed, in Persia, where he served for eight years. In April, 1904, he was appointed civil surgeon of Quetta, was transferred to the same post at Bikanir in March, 1906, and at Peshawar in May, 1909; and in December, 1910, was appointed Agency surgeon and administrative medical officer in Baluchistan. He received the Afghan Order of the Izzat-Afghanistan in 1907. He was a younger brother of Sir William Duke, K.C.S.I., late acting Governor of Bengal, and now a member of the Secretary of State's Council for India.

COLONEL JAMES CAMPBELL MORGAN, Army Medical Service, died suddenly of heart disease in London during the air raid on the night of March 7th, aged 53. He was born on July 18th, 1864, educated at the London Hospital, and took the M.R.C.S. and L.R.C.P. Lond. in 1886, also the D.P.H. Lond. in 1901. After serving as house-surgeon of the London Hospital, he entered the R.A.M.C. as surgeon on February 8th, 1887, became major on February 8th, 1899, lieutenant-colonel on August 30th, 1911, and colonel on March 1st, 1915, and was placed on half-pay on account of ill health on September 20th, 1916. He served on the North-West Frontier of India in the Zhoob Valley expedition of 1890, also in the Tirah campaign of 1897-98, when he was mentioned in dispatches (*London Gazette*, April 5th, 1898), and received the Frontier medal with two clasps. For some years he held the post of medical officer of the Duke of York's Royal Military School at Chelsea.

Universities and Colleges

UNIVERSITY OF OXFORD.

At a convocation held on March 12th the degree of D.Sc. *honoris causâ* was conferred upon William Carmichael McIntosh, M.D. Edin., F.R.S., late professor of natural history in the University of St. Andrews.

UNIVERSITY OF CAMBRIDGE.

At a congregation held on March 9th the following medical degrees were conferred, admission being by proxy:

M.D.—A. V. Poyser, V. F. Soothill.

THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS.

THE following list shows the present composition of the Council; the dates after the names are those of election:

President.—Sir George H. Makins, G.C.M.G., C.B., (1) 1903, (2) 1911, P. 1917.

Vice-Presidents.—Mr. Charters J. Symonds, C.B., (1) 1907, (2) 1915; Mr. W. F. Haslam, (1) 1908, (2) 1916.

Other Members of Council.—Sir W. Watson Cheyne, Bt., K.C.M.G., C.B., M.P., F.R.S., (1) 1897 (substitute), (2) 1901, (3) 1903; Sir Anthony A. Bowley, K.C.M.G., K.C.V.O., (1) 1904, (2) 1912; Mr. W. Harrison Cripps, (1) 1905 (substitute), (2) 1909, (3) 1917 (substitute until 1920); Mr. Bilton Pollard, (1) 1914; Sir C. A. Ballance, K.C.M.G., C.B., M.V.O., (1) 1910 (substitute), (2) 1914; Sir John Bland-Sutton, (1) 1910; Mr. D'Arcy Power, (1) 1912; Sir H. G. A. Moynihan, (1) 1912 (substitute till 1919); Mr. J. E. Lane, (1) 1913; Mr. L. A. Dunn, (1) 1913 (substitute till 1919); Mr. H. J. Waring, (1) 1913; Mr. W. Thorburn, C.B., (1) 1914; Mr. W. McAdam Eccles, (1) 1914; Mr. C. Ryall, (1) 1914 (substitute), (2) 1915; Mr. Walter G. Spencer, (1) 1915 (substitute till 1918); Mr. F. F. Burghard, C.B., (1) 1915 (substitute till 1921); Sir H. F. Waterhouse, (1) 1915; Mr. T. H. Openshaw, C.B., (1) 1916; Mr. Raymond Johnson, (1) 1916; Mr. Vincent W. Low, C.B., (1) 1916 (substitute), (2) 1917; Mr. James Sherren, (1) 1917.

* Sir Watson Cheyne, being President at the time of the Council elections in 1917, did not retire, although re-elected in 1909.

With the exception of three (one each from Birmingham, Leeds, and Manchester), all the members of the Council enumerated above are London surgeons.

There are four vacancies. It is understood that Mr. Pollard, Sir J. Bland-Sutton, and Mr. W. G. Spencer are seeking re-election.

Medical News.

THE Walsingham (Norfolk) Guardians, on March 6th, agreed to an increase of 10 per cent. in the salaries of the five district medical officers.

DR. GEORGE SIGERSON, professor of biology, University College, Dublin, has been elected an honorary Fellow of the Royal College of Physicians of Ireland.

UNIVERSITY COLLEGE HOSPITAL has received a donation of £2,000 from Mr. Middleton Jameson, in memory of his brother, Sir Starr Jameson, who received his medical education at the hospital.

At a meeting of the London Association of Medical Women on March 5th Lady Barrett opened a discussion on a scheme for improving the midwifery service throughout the country, with special reference to rural areas and illegitimate cases.

THE Henry Saxon Snell prize of the Royal Sanitary Institute is offered this year for an essay on improvements in apparatus and appliances for dealing with house refuse. Essays must be delivered on or before October 1st, 1918. Full particulars can be obtained from the Secretary, 90, Buckingham Palace Road, S.W.1.

THE King of Spain has founded a school in Madrid for the gratuitous maintenance and education of orphans of medical men, or orphans who are direct descendants of doctors. Provision is made for the reception of fifty boys and as many girls, and the number will be increased as further resources become available.

At a special general meeting of the Liverpool Medical Institution on March 7th the following addition to laws of the institution was passed by a large majority: No person who has at any time been a German or Austrian subject shall in future be eligible for election as an Honorary Member, Member, or Associate Member of the institution.

THE annual general meeting of the Royal Dental Hospital (Leicester Square) on Tuesday next at 3 p.m., at which the sixtieth year of its existence is to be celebrated, will be attended by the Bishop of London and Sir Francis Lloyd, the general officer commanding the London District. Many thousands of men from that district have been treated in the hospital in a special department, so that there has been no detriment to civilian patients.

A MEETING of the Tuberculosis Society will be held at the Royal Society of Medicine on Monday, March 25th, at 8 p.m., when a discussion on the need of hospitals for advanced cases of tuberculosis will be opened by Dr. Halliday Sutherland and Mr. Herbert Woolcoombe (London Charity Organization Society). The meeting is open to visitors.

THE war record of St. Thomas's Hospital shows that to March 6th 1,032 past and present students were serving, and that 48 had been killed in action or had died on service. The honours gained were one V.C., one G.C.M.G., one K.C.B., three K.C.M.G.'s, four C.B.'s, fifteen C.M.G.'s, two M.V.O.'s, twenty-three D.S.O.'s, thirty-nine M.C.'s and three bars to M.C., two C.I.E.'s, one G.B.E., four O.B.E.'s, one M.B.E., one C.B.E. For valuable service 132 men were mentioned in dispatches (188 times). The foreign honours include eight French, three Belgian, six Egyptian, seven Serbian.

THE Metropolitan Asylums Board has drawn the attention of the Ministry of National Service to the difficulty it has experienced in obtaining sufficient women for the nursing and domestic service of the many hospitals under the control of the Board. The shortage has been felt most severely in the infectious hospitals and sanatoriums, and the children's institutions have also suffered. The dearth is attributed to the greater attractions of other services at the present time, but we are under the impression that the terms offered by the Metropolitan Asylums Board have not at any time been very attractive.

A SPECIAL Canadian exhibition, arranged in a separate room, has been added to the war collection of pathological specimens at the Royal College of Surgeons, and will be opened shortly. The Canadian Government some time ago placed a special fund at the disposal of the D.M.S., and a staff of experts, with Major F. Lessore, a distinguished sculptor, at their head, have been engaged at No. 16 Canadian General Hospital, Orpington, better known as the Ontario Military Hospital, making wax and plaster models, coloured drawings, and coloured photographs of wounds and war deformities.

THE Minister of Munitions has issued an order that the war material to which Regulation 30A of the Defence of the Realm Regulations applies shall include all bismuth-bearing ores, bismuth metal, and alloys and salts of bismuth. No return, however, is required from any person whose total stock in hand, and not intended to be used for the manufacture or alloy of steel or other metal, does not exceed in the case of bismuth salts 56 lb., and in the case of bismuth metal or alloy thereof 14 lb. Any person is permitted to purchase bismuth metal and bismuth salts not exceeding in one calendar month a total of 10 lb. of metal or 56 lb. of salts, provided these are purchased and in fact used for pharmaceutical or medical purposes only.

THE annual report for 1917 of the Nurses' Co-operation shows that there were 463 fully trained nurses on the general staff, and 32 asylum trained nurses. The total number of cases nursed in 1917 was 5,720. Since the outbreak of war many of the members have been engaged in nursing soldiers, and during last year one of the military hospitals in England was entirely staffed by them. The Royal Red Cross decoration has been conferred on eleven nurses. The Co-operation (22, Langham Street, Portland Place, W.1) was established twenty-seven years ago to secure to nurses full remuneration from their work, subject to a deduction of 7½ per cent. for office expenses and for the maintenance of a policy by which they are insured under the Workmen's Compensation Act.

THE annual meeting of the Mental After-Care Association, which assists in the rehabilitation into ordinary life and employment of poor persons discharged from institutions for the insane, convalescent or recovered, was held on March 6th at the Mansion House, under the presidency of the Lord Mayor. There was a large and influential assembly. The adoption of the report was moved by Sir Francis Lloyd in an eloquent speech, in which he specially referred to the services rendered by the association to shell-shocked soldiers as well as to mental convalescents generally. Sir Frederick Taylor, Bt., M.D., Sir Charles Wakefield, Bt., Sir G. Wyatt Truscott, Sir George Savage, M.D., Lieut.-Colonel Ernest White, M.D., and Mrs. Henry Rayner and G. E. Shuttleworth also spoke. The report states that no fewer than 614 applications had been dealt with during the year 1917, and it is satisfactory to note that the balance sheet shows receipts £70 in excess of those for 1916 and all liabilities met. Still, with a dozen homes to maintain and new opportunities of usefulness springing up, especially in connexion with soldiers' and sailors' wives and relations, more funds are still needed and will be gratefully received by the secretary, Miss E. D. Vickers, Church House, Westminster.

Letters, Notes, and Answers.

AUTHORS desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are:

Queries, answers, and communications relating to subjects to which special departments of the *BRITISH MEDICAL JOURNAL* are devoted will be found under their respective headings.

QUERIES AND ANSWERS.

A QUESTION AS TO MARGARINE.

DR. G. N. MEACHEN (Braintree) asks whether paraffin oil is employed in any way in the manufacture of margarine. On two occasions recently he has observed the odour of acetylene in the breath of two members of his family, once after partaking of some margarine purchased at a local store, which left a strong after-taste of paraffin in the mouth, and again after eating some ginger cakes bought at a town some twenty miles distant, which had a very disagreeable greasy taste.

A CASE FOR DIAGNOSIS.

SALOP asks for advice with respect to the following case: Lady, married, 35, two children (youngest 2 years). Last eight months constant pain in left chest, arm, left side of head and neck, with pain on swallowing. Frequently pain is paroxysmal over precordia. Pulse 80, regular, but of low tension. Respirations shallow and hurried when in pain. Physical examination reveals slight softening of apical second sound, but no dilatation. Hyperaesthesia over whole of affected area. Radiograph of chest does not show any abnormality. Iontophoresis, radiant heat, massage, liniments, and blistering have no effect. Only morphine hypodermically does any good, and this often fails, except in large doses, which are undesirable.

VIRILITY OF LOUIS XVI.

INQUIRER.—The "mechanical impediment" referred to by Mr. Hilaire Belloc as having "gravely distorted the first years of his (Louis XVI's) marriage" was phimosis. For this he was operated on in June, 1777, by Lassone, first physician to Marie Antoinette, with complete success. For some unknown reason the operator's report on the case has never been allowed to see the light. Sainte-Beuve said: "Louis XVI was not impotent any more than a man is dumb because he stutters; husband or King, he was the same, ashamed and embarrassed." The King was of cold temperament, unlike his father and some other Bourbons. The Queen and her mother, the Empress Maria Theresa, were for dynastic reasons anxious for offspring, and the royal couple had been married for seven years without this result. The matter is dealt with in detail by Dr. Cabanès in *The Secret Cabinet of History*, translated by W. C. Costello (Paris: Charles Carrington, MDCCCXCVII, p. 65, et seq.).

INCOME TAX.

M. S. F. asks whether he is bound to furnish the assessor of taxes with his book containing the particulars of his treatment, etc., but no specification of fees.

* * The assessor as such has no authority to require production of any books, but the Commissioners when hearing appeals have the right of calling for such evidence as they may think fit, the penalty for non-production being apparently confirmation of the assessment. The book in question might have some evidential value as a record of work done for which charges could be made; but, as no record of charges appears therein, we should doubt whether the Commissioners would call for it.

LETTERS, NOTES, ETC.

A REQUEST TO RURAL PANEL PRACTITIONERS.

DR. J. P. WILLIAMS-FREEMAN (Weyhill, Andover, Hants) asks any country practitioners who have kept records of the distance travelled and of the number of visits of all description paid during one or more years to furnish him with the average number of miles travelled per visit, and also the name of the sanitary area in which they reside, so that the density of the population from the *Medical Directory* may be ascertained. Dr. Baigent and others have suggested that

travelling allowances should vary with the latter factor. Dr. Williams-Freeman thinks that a rough correspondence must exist between the two, and suggests that it is for rural practitioners to work out a scheme that will redress their grievances. He would welcome any other statistics concerning country practice.

COMPULSORY RATIANS: REGULATIONS FOR INVALIDS.

(Correction.)

THE Ministry of Food desires us to say with reference to the notice published last week (p. 290) concerning compulsory rations and regulations for invalids, that while most of these regulations were suggested in a memorandum presented to the Ministry of Food by the Committee of Reference of the Royal Colleges of Physicians and of Surgeons and the Central Medical War Committee, the complaints "coeliac disease," and "pancreatic insufficiency" were not included in that memorandum. They were added at the instance of the Scientific Adviser after consultation with one of the medical referees to the Ministry of Food.

DIETARIES IN TUBERCULOSIS SANATORIUMS.

THE medical superintendent of a sanatorium sends us a note suggesting that the dietary temporarily approved by the Local Government Board for tuberculous persons in sanatoriums (p. 290) would be liberal in normal times, and is, in view of the conditions now prevailing, unnecessarily generous. He believes that it is in excess of what many sanatoriums have been allowing, without any hardship, during the past twelve months. He asks whether, as a matter of public policy, it would be desirable to give to advanced cases of consumption, in whom there is no question of restoration to useful work, a more liberal ration than to munition workers doing hard physical work. He asks what scale of rations it is proposed to allow to patients when they leave an institution and return home. In the institution with which he is connected the patients' rations are being reduced by the local Food Committee, but the effect of the proposed new scale would be considerably to increase them.

DIET IN THE TROPICS.

WE learn from *Nature* that an interesting report on the diet, nutrition, and excretion of Asiatic races in Singapore has been prepared by Dr. J. Argyll Campbell, at one time assistant to Sir E. A. Schäfer in Edinburgh and now Professor of Physiology in the Singapore Medical School. He found that the energy value of the diet of a Chinese, a Tamil, or a Malay medical student was only about 1,600 calories. That of a Brahmin was higher, but, the diet being vegetable, was to a large extent unutilized. For comparison he quotes the diet of an Anglo-Indian, which, according to McCay, was 2,800 calories, and a Filipino, which was 2,630 calories. He suggested that the low energy value of the Singapore diet might be due to the moist atmosphere, which retards loss of heat by evaporation, so that less food is required. Another contributory cause suggested is the small amount of muscular exercise taken by the Singapore student. Although Europeans in the tropics are not inclined to take much exercise, they cannot keep healthy on a European diet unless they do so. Professor Campbell found the Singapore students to do as much brain work as his previous European students did. His essay was published in the *Journal of the Straits Branch of the Royal Asiatic Society* (1917).

POTATO BREAD IN THE EIGHTEENTH CENTURY.

IN these days when so much ingenuity is being displayed in the application of unusual materials to the making of bread it is interesting to find that Voltaire used potato for the purpose. Antoine Augustin Parmentier, who did so much to promote the cultivation of that vegetable in France, sent him a paper on the subject. In a letter, dated "Ferney, April 1st, 1775," the philosopher, in apologizing for delay in acknowledging receipt of the "excellent memoir," says he has had a very tasty bread made of potato mixed with one-half of wheat flour. Voltaire himself no longer ate potatoes, but he had given the bread to his labourers in times of scarcity with the greatest success. The letter, which is addressed to "Monsieur Parmentier, Apothicaire major, of the Hôtel-Royal des Invalides, Paris," has recently been unearthed and is published in the *Chronique Médicale* of February 1st, 1918.

COMMON COLDS AND THE CONTAGION FOR LOBAR PNEUMONIA.

THE frequent association of common colds with pneumococci and the occasional occurrence of a bad cold before the onset of pneumonia are well known; but the determination of the strains of the pneumococci associated with nasal catarrh as tabulated by American bacteriologists (vide *BRITISH MEDICAL JOURNAL*, 1918, i, 57) has apparently not hitherto been investigated. By injecting the nasal secretion or sputum into mice Engenia Valentine (*Journ. Exper. Med.*, Baltimore, 1918, xxvii, 27-29) recovered pneumococci in 37 out of 65 cases of common colds, and by direct plating on blood agar pneumococci were found in 6 additional cases. By agglutination reactions in these 43 cases the type of the pneumococci was determined as follows: Group I, 2 cases; Group II, 2 cases; Group III, 4 cases; Group IV, 35 cases. The cases with Group I pneumococcus had not been in contact with any pneumonic case, were seriously ill, and the pneumococcus constituted at least 75 per cent. of the organisms in the sputum. These data strongly suggest that it was the etiological agent in these

colds. If this deduction is correct, such cases of common cold must be added to the known sources of contagion for lobar pneumonia—namely, a case of pneumonia, a convalescent patient, and a contact carrier.

MEDICAL PRACTICE IN MALAYA.

A CORRESPONDENT who has been both a Government medical officer and a private medical practitioner in the Straits Settlements and Federated Malay States writes to warn any practitioner who may be thinking of selecting that field for his future career, of the inadequate remuneration which the Government service offers. Under the new scheme which came into force some three years ago, the Government service pays an initial salary of £350 + £100 duty allowance. The increment is £50 in the first year, and afterwards only £20 a year, so that it takes a man fourteen years to reach the £600 limit. Free quarters are not now allowed. Our correspondent considers that when the cost of living and the unhealthy character of the climate are taken into consideration, a man is better off at home, even in war times, with £300 a year than in Malaya with £600 a year, even making allowance for the pension, meagre as it is, should he live to receive it.

THE CASE OF DR. J. HENDERSON BELL.

THE Rev. Dr. Pentreath (Adderley Rectory, Market Drayton) regrets the delay in sending copies of the *précis* of the above case. They will be dispatched as soon as they are received from the printer. Much interest is being taken in this case judging from the many applications he has received for copies of the *précis*. Dr. Pentreath will be happy to send a copy to any one who will send him a stamped addressed envelope to the above address.

TREATMENT OF TUBERCULOUS MESENTERIC GLANDS.

IN connexion with the report of a discussion on this subject published in the *JOURNAL* of February 23rd, p. 232, Dr. Lawrie (Ramsbottom, Lancashire) writes to recall the formula he gave in the *JOURNAL* of November 29th, 1913, p. 1433. It was a mixture containing precipitated calcium carbonate, gr. 4, creosole, minim 1, mucilage of tragacanth, as much as is necessary, with potassium iodide $\frac{1}{2}$ gr., and saccharine $\frac{1}{2}$ gr. in peppermint water to 2 drachms every four hours for a child of 5 years. Last November he saw a girl of 8 years who had been ill since the previous April, with loss of flesh and appetite, anaemia, copious night sweats, colic, and tumid abdomen. She began to take the mixture on November 12th, showed some improvement at the end of the month, and at the end of February was apparently quite well, and had put on flesh. The mixture was discontinued after January 12th. Dr. Lawrie expresses the hope that some one with greater opportunities may give this treatment, which he considers almost a specific, a trial.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE following subscriptions to the Fund have been received during the week ending March 11th:

	£	s.	d.		£	s.	d.
Dr. Sidney P. Phillips	5	5	0	Dr. J. B. Naden	3	0	0
Mr. George W. Thompson	10	10	0	Mr. A. Wertheimer (per			
Mr. Leonard Stearn	1	1	0	Dr. Sidney Phillips)	10	0	0
Mrs. Mary Striager,				*Dr. Alfred Cox	1	1	0
M.P.S.	1	1	0	Dr. A. Hugh Thompson	2	2	0
Dr. Reginald J. Haubury	2	2	0				

* Monthly subscription during the war.

Subscriptions to the Fund should be sent to the Treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

THE DEFINITION OF PROSTITUTION.

A NEW definition in criminal law having some medico legal interest was given by the Court of Criminal Appeal on March 11th. The point was the definition of the term "prostitute." In the case in point it was shown that the girl (aged less than 15) was *virgo intacta*. The Court of Appeal decided that the term common prostitute used in the statutes was not limited so as to mean one who offered her body for hire for the purpose of natural sexual connexion only; prostitution was proved when it was shown that the woman offered her body for purposes of general lewdness.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *post restante* letters addressed either in initials or numbers.

An Address

ON

PRIMARY SUTURE OF WOUNDS AT THE FRONT IN FRANCE.*

BY

SURGEON-GENERAL SIR ANTHONY BOWLBY, K.C.M.G.,
K.C.V.O., A.M.S.,
CONSULTING SURGEON, BRITISH ARMIES IN FRANCE.

1914.

Soon after the commencement of this war surgeons were brought in contact with a terribly septic condition of the wounds, and extensive prevalence of spreading gangrene. It was perhaps natural that those who were not at the seat of war should attribute these occurrences to the imperfections of those who were, and it was also natural that everybody should try and improve matters by advocating various methods of treatment which had either in their experience proved of value in civilian surgery or were theoretically likely to be of use.

The remedies advocated fell into two classes: First, strong antiseptics, which it was believed were capable of arresting sepsis if applied early enough and strong enough. Second, the acceptance of the fact that antiseptics were of no use, and that no treatment could possibly so antagonize the innumerable bacteria as to permit of the early closure of the contaminated wounds, which therefore must be left as widely open as possible, and encouraged to discharge.

The first disappointed us, and may be described as a counsel of false hopes; the second remained as a counsel of despair as far as primary union was concerned, and it was left to the surgeons with the troops to try and ascertain by the long but sure tests of the experience of many wounds whether either class of counsellors were right. It was only too evident before long that both of the methods advocated left much to be desired, and it was soon appreciated that the surgeons of all the combatant armies, of whatever nationality, were face to face with wound conditions which were quite new to them and which presented problems only to be solved by careful and laborious investigation. No one at that time was in a position to dictate to others what was the answer to the questions, What is the best method of combating the all-prevailing sepsis? and How can wounds be got to heal quickly and safely?

1915.

But as time went on the darkness of ignorance was slowly illuminated, and things became clear which had long been obscure. We realized that we had attributed too much power for evil to the microbe invasion; that the infection was too gross to be combated by antiseptics; and that the source of the danger was to be sought for in the damaged or dead tissues contaminated by the mud of the manured fields and in the portions of the muddy clothing and the missiles which were buried in the wounds. We learnt that a tissue deprived of its blood supply was the focus of danger, and, lastly, that our most dreaded foes, the bacteria of "gas gangrene," lived and flourished chiefly on the muscular fibres which had been crushed by the missiles. We knew now why it was that our early attempts to combat sepsis had failed, and on this foundation composed of facts we began to build an edifice which, though still incomplete, is infinitely more secure than those we had tried to erect upon the shifting sands of ignorance and theory.

At first we thought it enough to open up wounds and to remove missiles, but as soon as a little more knowledge was acquired we began to excise the damaged tissues, at first very sparingly, but, as we learnt to recognize the signs that indicated the extent of muscle crushed or infected, more and more attention was paid to the complete removal of as much as seemed likely to prove a dangerous centre of infection. And to-day we know that the one and most necessary method of treatment is the careful and thorough mechanical cleansing of the wound and the complete removal of all dead or partially devitalized tissue. Without this, antiseptics are useless, and, in proportion as technique is good, and excision can be done early and can be really complete, antiseptics applied inside the

wound are merely accessory. The one condition for success is that this complete surgical cleansing must be performed before the bacteria have had time to penetrate too deeply or to spread too far, but of this there is more to be said later.

In the early days of the war no cases did worse than those in which the surgeon had completely sutured the wound, and the experience of many surgical disasters prevented any return to such treatment for a very long time. The consequence was that, after an operation of excision, the wound was habitually left open, and only after a disinfecting process, such as that provided by the ingenuity of Carrel, was any attempt made to close the wound by secondary suture.

THE BEGINNINGS OF PRIMARY SUTURE.

It is interesting to note how the systematic treatment by primary suture began with the knee-joint, and how it has grown. Early in the war, wounds of the knee-joint were very commonly followed by suppuration of the most severe and dangerous kind, and this although many of the surgeons in France knew the danger of drainage tubes in the articulation and avoided it. But it was soon realized that many perforating wounds of joints did well, even although the synovial fluid was infected, if only they were not opened up and drained, and the natural conclusion was that if the wounded joint could be closed, after the removal of missiles, and after thorough surgical cleansing, it might also do well. As soon as this practice became common, not only did many of the joints not suppurate, but the skin wounds also healed by first intention in a very large proportion of all the cases, and we found that the surgical ideal of a healed aseptic wound had been attained.

Very cautiously, the practice of primary suture was applied to other wounds, and nowhere was it of greater value than in wounds of the brain and fractures of the skull. Injuries which had been treated in the early days by drainage with bad results were now treated by surgical excision and primary suture of the scalp with infinitely better results. Wounds of the abdomen were treated on the same lines, and the abdominal wall was closed after operations on the intestines or other viscera.

1916.

In 1916, and still more in 1917, operations began to be done on many wounds of the lung, and as it was soon found that success depended on an immediate closure of the pleural cavity after the operation, this closure was fortified by a corresponding suture of the skin after all damaged muscle and splinters of ribs had been removed. Here again success followed in many cases, and primary union was thus obtained in wounds which involved injured muscles and fractured bones. The position at this stage was that the knee joint, the scalp, the abdominal wall, the thoracic wall, could all be closed by primary suture. Then why not other wounds also? And the answer was forthcoming from every side, "Other wounds of the limbs can be similarly closed, and many of them are being successfully closed by many surgeons." It was the difficulty of dealing with large masses of devitalized muscle infected by microbes that made limb wounds so much more difficult to deal with than the aponeurosis of the scalp or the fibrous capsule of the knee. To this was added the impossibility of excising large vessels and nerves exposed in a wound, and the consequent imperfection of the excision operation. In cases of extensive fracture and comminution of dirty bone the task was still more difficult when the surgeon endeavoured to make sure of reaching every portion of the damaged area. No doubt the great majority of the failures were the result of the very natural unwillingness to excise enough of the damaged muscle, but experience, surely though slowly, taught the necessary lessons, and, by the exercise of a scrupulous asepsis combined with a meticulously careful surgical technique, more and more successes were attained and wounds were closed which a few months earlier would have been considered quite beyond the possibility of suture.

PROGRESS IN 1917.

The year 1917 saw a general acceptance of the proposition that union after primary suture was, under favourable conditions, a reliable surgical fact, and the outlook of

* Delivered at a meeting of the Royal Society of Medicine on February 15th, 1918.

surgeons on the treatment of wounds was altogether different in December from what it had been in January.

At the meeting of the Surgical Conference of the Allies in Paris in May, 1917, it was agreed that operation "may be followed in some instances by primary closure of the wound, notably in the case of wounded joints," but in the following November the conclusion arrived at was: "Since our last session the disinfection of wounds has passed from the domain of the chemist to that of the surgeon. Primary suture has taken the place of secondary suture and has become the method of choice."

It is of interest to see what had happened during these six months. There was a general consensus of opinion that the time had come to try the primary suture of wounds on a larger scale, and in both the British and French armies, as well as in the Belgian, many surgeons whose hospitals were favourably situated took the matter up. A large hospital with five wards on the pavilion system was occupied in July by both British and French units, and, working in close touch with each other, the surgeons of both nations proceeded with similar investigations. The circumstances were favourable, for wounded could be brought in quickly, could be accommodated under excellent conditions, and could be retained for an indefinite time, so that it was easy to follow wounds to the end of their surgical course.

Of those patients admitted to the British unit no less than 98 per cent. were injured by shells or bombs, so that the wounds were of a very severe type and the test of the surgery was correspondingly severe. The results showed that, of 433 patients operated upon, in 67 per cent. the wounds healed by first intention, while in a great many of the remainder they healed with only a slight surface suppuration.

The results obtained by the French surgeons were equally good, and, as the wounds thus treated were of every variety, it was clear that the treatment was applicable to every class of injury. In the British unit no antiseptics were employed, in the French unit ether was used in almost all the wounds.

We had previously initiated, in June, another series of observations in a different army, and for this investigation we employed flavine. The results of this trial were recorded¹ by Captains Drummond and McNee, and they showed that of 32 wounds closed at the time of operation 30 healed *per primam*, and 10 others healed similarly which were left open for one or two days and then sutured, making a total of 40 successful closures out of 42 cases. Further experience has confirmed the conclusions originally arrived at, that while flavine is not a good application to granulating wounds, it is a very useful agent in the treatment of freshly excised wounds. In the army area where it has been chiefly employed successful primary suture has been performed in well over 70 per cent. of the cases.

In yet another area, Captain Haycraft closed 116 wounds

after treating them with a solution of soap, and his results were recorded in the BRITISH MEDICAL JOURNAL for January 19th last (page 80). Of these cases 75 healed *per primam* and 16 more after superficial suppuration. Thirty-eight of the cases were complicated by fractures of the long bones, and of these 28 healed *per primam* and 5 more after superficial suppuration.

Progressive Improvement in Results.

It will thus be seen that various surgeons, using various methods, obtained success in a very large percentage of all their operations, and similar results were being obtained in many other casualty clearing stations in different parts of the line. Meantime, the prolonged and severe fighting during the autumn months fully occupied the time of the surgeons in France. But as soon as a period of comparative quiet succeeded, we began again our observations and criticized our own methods with a view to deciding various doubtful points. To this end we arranged

that one of the casualty clearing stations should become a "hospital of observation," and in this unit we have at the present time treated 175 wounds of the extremities, including many fractures. The operative work has been done by four or five surgeons, and they have employed various antiseptics, or else in some cases, and chiefly the slighter wounds, no antiseptics at all. The work here has also been helped by very competent bacteriologists, and careful records of wound infections have been kept. A complete report will be published shortly.

It is too early to draw any final conclusions on the bacteriology of the wounds which we have been treating, but it is already evident that those which heal *per primam* may do so in the presence of various organisms. Thus, Captains Adrian Stokes and Tytler report that

fifty-eight cases were infected with anaerobes, streptococci, staphylococci, diphtheroids, or combinations of these. Forty-two of these were successes (as primary sutures), and 16 were failures. Of the 58, 32 grew streptococci—6 of these were of the haemolytic variety, and of these 5 were failures; 25 were non-haemolytic, of which 6 were failures. We are inclined to agree with Le Gros and Tissier that the streptococcus, especially the haemolytic variety, is by far the most important organism with which we have to contend.

And Captain McNee, in the report on flavine, to which I have already alluded, says:

Complete bacteriological sterility was rarely obtained, yet the patients were obviously doing well, and the wounds showed no signs of local or spreading inflammation. In several instances secondary suture (after a day or two) was adopted with complete

FIG. 1.—Drawing from skiagram: Case of fractured humerus treated by primary suture.

FIG. 2.—Drawing from skiagram: Severe comminuted fracture of femur into knee-joint. Closed on the fourth day.

FIG. 3.—Another view of the fracture shown in Fig. 2.

success, while numbers of organisms were still recognizable which cultures showed to be viable.

It is, indeed, evident that some bacteria may be shut up in a recent wound and do no harm, provided that all dead tissue and all foreign bodies have been removed.

Fortunately, the clinical evidence as to how a wound is doing is generally easy to obtain. A slight rise of temperature often follows suture, especially if it is done after an interval of a day or two, but, in the absence of other evidence of infection, it is not a reason for opening up the wound. On the other hand, the surgeons have found that all the cases infected by haemolytic streptococci showed such definite evidence of infection within twenty-four hours that, apart from the report of the bacteriologist, it was clear that the wounds required to be opened up, for the skin edges were red, swollen, and indurated, and a copious exudation oozed from between the stitches. It is fortunate that such reliable evidence can be reckoned on, for it might be impossible to wait for a bacteriological report.

The Factors of Success.

But if success is to be obtained it is necessary to take every precaution to ensure it, and one most important precaution is the use of x rays, for in many cases a foreign body will be left, unknown to the surgeon, unless a radiograph has been taken or a screen examination has been made before operation. It is not contended that this examination is invariably required in every slight case, or in through-and-through bullet wounds, but wounds are not always what they seem, and every precaution is worth considering.

The choice of suitable cases for suture demands a considerable experience of wounds at the front, and is not a matter to be lightly decided. We find that about one-half of the cases at present being admitted to our "observation casualty clearing station" are not suitable, and the experience of Surgeon-General Wallace gives the same proportion. Some are suffering too much from exposure, shock, or recent bleeding, to bear a prolonged operation. Some have too many wounds to allow operations to be done on all of them, while in others the destruction of skin by the missile is too extensive. Some wounds are already evidently inflamed, and others show either commencing cellulitis or gas gangrene. Not a few arrive after too long a time for closure to be safe, even if none of these conditions are present.

Danger of Delay.

This brings us to the question of "time." A little consideration will show that no time rule can be laid down to apply to all cases. Thus, an open gutter wound involving only skin and subcutaneous tissue might be safely excised and treated twenty or thirty hours after its infliction, if it showed no signs of infection, whilst a man with a large wound and a fracture of the thigh who had been soaked in mud for a similar time would not be a safe subject for closure. A good deal also depends on whether or no dangerous organisms have invaded even a superficial wound. But, allowing for these differences, it must still be said that the earlier the patients are operated upon the higher

is the average of success in every class of wound. Delay means danger.

At the Allies Surgical Conference in November, 1917, M. Duval reported that of the "lightly wounded" without fractures 80 per cent. had been successfully sutured within eight to twelve hours of injury, and M. Tuffier informs me that equally good results were obtained in the wounds not going as deep as the muscles even after twenty-four hours. Much must also depend on the weather, for a patient might lie out for the whole of a warm summer's night with less harm to his wound than if he lay immersed in winter mud and water for a couple of hours. Every effort should always be made to bring patients into the casualty clearing station as rapidly as possible.

Rest after Suture.

But although the possibilities of success are largely dependent on conditions antecedent to the arrival of the patient in hospital, it has been established that another important factor is keeping the patient at rest after suture has been performed. It seems certain that many sutured wounds are caused to ooze and to become distended if patients are sent journeys by road or rail soon after operation, and it is now a settled policy that a wound is not to be sutured

at the time of operation unless the patient can be retained for at least seven days, or more in bad cases, at the casualty clearing station where the operation is done. And, as there are many occasions on which it is not possible to retain all the wounded, it happens that cases must be sent down to the base hospitals after excision has been done, with the wound unsutured and lightly dressed with sterilized gauze. The French surgeons have soaked the gauze in ether, and we have generally used flavine, 1 in 1,000, or bipp. Personally, I prefer flavine, because it has no toxic or irritating qualities, and the gauze soaked in it (and kept moist by jaconet and non-absorbent wool) does not stick to the tissues, and leaves a good surface for suture.

"Delayed Primary Suture."

The French surgeons have called the suture which is done after the lapse of a day or two "*la suture primitive retardée*," and we have been in the habit of calling it "delayed primary suture," leaving the term "secondary suture" for the closure of granulating wounds. It thus happens that a wound is often excised by one surgeon, and when the patient arrives at a hospital where he can remain at rest, sutured by another. Our observation at the front on the patients we have retained there entirely confirms the opinion of the French surgeons that there is no disadvantage in delaying suture for forty-eight hours or more. On the contrary, most surgeons with recent experience of excision and primary suture consider that there are many wounds which do much

better if they are not closed at once. For, where there is extensive laceration or a bad fracture the oozing cannot always be stopped while the patient is on the operating table, and therefore it is not wise to close such a wound then and there. If twenty-four or forty-eight hours are allowed to elapse all oozing has ceased,

FIG. 4.—Drawing from skiagraph: Fracture of femur. Closed on third day.

FIG. 5.—Drawing from skiagraph: Fracture of humerus. Primary suture.

FIG. 6.—Drawing from skiagraph: Fracture of tarsus and metatarsus. Suture on fifth day.

and suture is much more often successful than it otherwise would have been. Here also experience is required to know which wounds should be treated in one way and which in another, and much of the success obtained will depend on the decision.

It is also wise not to suture any wound at the time of excision if there is any material doubt as to whether suture should be done. It is much better to leave such a wound open till enough time has elapsed to settle the question. We generally give gas and oxygen for the "delayed suture," but various methods of local or general anaesthesia are employed. If drainage is required it should be ensured by the insertion of a doubled piece of sterilized silver wire, and not by either drainage tubes or gauze; but the sooner the wound can be completely closed the less will be the chance of infection and suppuration. If a drainage tube is used and is left in long enough suppuration is ensured.

PRINCIPLES TO BE OBSERVED IN PRIMARY SUTURE.

But, while success depends on many conditions which are beyond the control of the surgeon, it depends very largely on the surgeon himself. Let it be clearly realized that primary suture of wounds is more likely to end in disaster than in benefit unless the operation is most carefully performed, and this implies, in the first place, the most minute aseptic precautions, such as are commonly practised by British surgeons in their most serious operations in civil work. No more skin should be excised than is absolutely necessary; even if badly damaged it can often be saved. In the next place, the operation must be done most deliberately and thoroughly, so that no part of the wounded area escapes treatment. This all means a good deal more time than is required for the opening up and cleansing of the average infected wound which is not suitable for suture, but it is time well spent, especially if the case is one of fracture.

On the other hand, operation for the excision and cleansing of small superficial wounds can be done quite quickly, and no class benefits more than these by this method of treatment.

It is in the class of "slightly wounded," with injuries of the "soft parts," or "flesh wounds," that early and careful operation yields the highest proportion of success. Hitherto, when wounded are numerous, these patients have habitually been carefully dressed but not submitted to operation. Often many weeks or months have elapsed before their wounds have finally closed, and for all this time they have been inmates of hospitals and frequently confined to bed. Some of them have had serious complications as well. Successful suture makes a complete cure of such patients in a time measured by days or weeks instead of by months.

The benefit to the more seriously wounded is still more obvious. Not only are compound fractures converted into simple ones, but the period of confinement to bed and to hospital is greatly shortened. The absence of sepsis is well seen in the features of the patients, whose good colour tells its own tale. There is none of the general loss of flesh, none of the shrunken and stiff, wooden-like limbs which we see after prolonged suppuration, none of the stiffness of all the joints of the affected limb which is so long in recovering.

I am indebted to Surgeon-General Cuthbert Wallace for the following figures of all primary sutures performed between May and December in the army to which he acts as consultant. They include the figures I have quoted by Drummond and Haycraft.

Primary Sutures, May-December, 1917.

	Total.	Healed by First Intention.	Healed after Slight Suppuration.	Suppurated.	Not known.
Superficial wounds ...	119	74	9	—	36
Deep wounds ...	260	184	38	30	8
Fractures ...	131	93	17	21	—
Amputations ...	37	24	5	8	—
Joints ...	79	69	—	10	—
Total ...	626	444 (75%)	69	69	44

One Hundred Consecutive Cases of Compound Fracture Treated by Primary Suture.

	Total.	Healed by First Intention.	Healed after Slight Suppuration.	Suppurated.
Femur ...	18	11	2	5
Tibia and fibula ...	5	4	—	1
Tibia ...	10	9	—	1
Fibula ...	2	2	—	—
Humerus ...	34	26	6	2
Radius and ulna ...	3	3	—	—
Radius ...	15	12	3	—
Ulna ...	15	8	4	1
Total ...	100	75 (75%)	15	10

It will be seen that out of a total of 626 cases, 68 per cent. were successfully sutured and healed *per primam*.

At the "observation hospital" 123 wounds have been sutured, with success in 83 per cent.

Thus, in these three separate areas there is a total of 1,202 cases under various surgeons, with success in about 70 per cent. Moreover, in many of the remaining 30 per cent. there was a very early closure of the wound in spite of superficial suppuration.

The success obtained in cases of fracture is also very striking, for the table sent by Surgeon-General Wallace shows 75 per cent. of successes. The results of the observation hospital support this.

Statistics of "Observation Hospital."

	Success.	Failure.
Humerus ...	5	—
Forearm ...	1	—
Metacarpus ...	1	—
Femur ...	3	5
Tibia and fibula ...	2	—
Tibia ...	4	1
Fibula ...	3	—
Tarsus ...	4	1
Metatarsus ...	2	—
Total ...	25	7

That is, 72 per cent. of successful suture.

Recoveries after Suture.

The amputation cases at the observation hospital have been few, but they also have been very satisfactory. Of 11 cases all the patients have recovered. Seven were amputations through the thigh, 2 through the leg, and 2 were Syme's. Ten out of the 11 healed soundly either after immediate suture or after closure of the flaps on the third or fourth day. One failed to unite, and suppurated.

Another very satisfactory result is that the whole of the patients have, so far, recovered whose wounds were sutured at the observation hospital. There has as yet been no death in the 175 patients operated upon for suture, whether the latter was successful or not. They are not all sufficiently recovered to be free from danger at the present moment; some have been too recently operated upon, therefore, for their cases to be included in the figures I have quoted. But, apart altogether from the question of primary union, it is a very important fact that no one has yet died. Yet many of these men were very badly injured. More than 40 of the 175 had fractured bones; 2 of them had torn femoral arteries (but have kept their limbs after ligation of the vessel); 2 had torn posterior tibial arteries; 8 had wounds opening the knee-joint, in one of which the patella had to be excised; several had fractures opening the elbow-joint; more than 20 had multiple injuries; 2 of them required transfusion of blood. I do not believe that all these men would have recovered if their wounds had not been closed.

Ample Man Power Essential.

I have pointed out the chief essentials for the success of primary suture, but the application of this treatment must remain largely a question of man power from first to last.

First, it is only by having enough stretcher-bearers that we can get in the wounded who cannot walk, and, one must add, enough strong stretcher-bearers. If men are not brought in "soon" their wounds cannot be sutured, so it is really a race against time and against the microbic infection, which has got the start of both stretcher-bearers and surgeons. Difficulties exist which, though they might not be thought of by the inexperienced, explain why men may arrive too late without anyone being to blame. Both many and strong stretcher-bearers are required, and it is difficult to provide too many. It is not clear that delay in reaching a casualty clearing station may be unavoidable.

Need for More Surgeons.

In the second place, primary suture of wounds evidently requires surgeons in proportion to the numbers of the wounded. We have already been able to operate on almost all the most serious cases at the casualty clearing stations in recent battles, and one wounded man out of about every three wounded was passed through the theatre and operated upon under an anaesthetic. The remaining two-thirds were sent to the base, and many of them were in the class of the "lightly wounded."

In future, the wounds which have been excised but not sutured at the front, as well as probably some not yet excised, will be dealt with by hospitals placed further back than the casualty clearing stations, and thus, if there are enough surgeons, and if wounded are not too numerous, we hope to be able to ensure that a majority of all suturable wounds shall heal *per primam*. If our expectations are realized it is evident that patients will not be so long in hospital, and that there will be less strain on staffs at the bases both in France and in England. Much depends on the incidence of the wounded and on the supply of surgeons. It is at least evident that we shall need more operators than we have had previously.

I should like here to put in a special plea for plenty of medical officers in France. I hear from various surgeons at other seats of war, and amongst them men who have served in France, that the prevalence of gas gangrene is infinitely greater in France than elsewhere. It is the danger of this which makes early operation so necessary, and it is the number of these essential operations which calls for so many surgeons.

The accompanying figures, drawn from radiograms, illustrate some cases of fracture which were treated by "primary suture."

CONCLUSIONS.

Sufficient care has now been exercised, and sufficient experience gained, to allow the primary suture of wounds to be placed on a definite footing, and to permit the following conclusions to be drawn:

1. The most important treatment is the careful cleansing of every part of the wound, and the subsequent complete excision of all dead, badly damaged, or grossly infected tissue. It is never necessary or right to remove more than a very thin edge of skin.

2. Complete asepsis is of the highest importance, and experience at the front is essential in order to select suitable cases.

3. The wound may be sutured at once, or may be left unclosed for one, two, three, or four days. It can then be sutured, with results which are identical with those obtained by immediate suture.

4. If after operation the wound is not sutured it should be dressed in such a way that it need not be disturbed till the time for closure has come.

5. If the wound is sutured at the time of operation, the patient should be retained in hospital for not less than a week. If he cannot be retained then the wound must not be sutured.

6. It is seldom that, even after the most careful operation, the wound is sterile, and bacteria can generally be found in the secretion on the following day. The presence of a few bacteria, whether anaerobes or the ordinary pyogenic forms, does not prevent healing of the wound. Streptococci which can haemolyze blood constitute the most dangerous form of infection, and if they are detected the sutures should be, at once removed.

7. No definite rule can be laid down as to the lapse of time after which suture should not be done, but the sooner the wound can be operated upon the greater is the probability of success. It can be sutured later.

8. If the wound edges are found on examination to be already indurated and inflamed, or if definite gas gangrene has already commenced, the wound must not be closed. Whenever there is any doubt at all it is best to leave the wound open, knowing that it can be equally well sutured in a day or two if this appears advisable.

GUNSHOT WOUNDS OF THE ABDOMEN AT A CASUALTY CLEARING STATION.

150 CONSECUTIVE OPERATIONS FOR PENETRATING
ABDOMINAL WOUNDS.

BY

CAPTAIN R. CHARLES, R.A.M.C.(T.C.).

SINCE November, 1914, I have had the opportunity of observing and treating a large number of gunshot wounds of the abdomen. I cannot lay claim to breaking fresh ground, yet in my series many of the cases present points of great interest, and illustrate the difficulties and the wide field of this type of surgery. It is not proposed to describe minutely or discuss either the various kinds of injuries produced by various missiles, or the signs and symptoms associated with the lesions of the different abdominal viscera.

DIAGNOSIS.

Difference of opinion sometimes arises as to whether a gunshot wound of the abdomen involves the peritoneal cavity or not; indeed it is sometimes impossible to tell without a laparotomy, for the signs and symptoms usually associated with these cases are not constant. Experience will usually settle the point in each particular case.

The following points taken collectively are important:

1. *Position of the Injury.*—It is first necessary to determine if possible the direction of the track. The entrance and exit wounds give an idea of the path of the missile and the structures likely to be involved. The absence of an exit wound does not necessarily mean that the foreign body is lodged in the abdomen. The possibility of its being buried in the parietes must be excluded.

2. *The facial expression* is usually one of anxiety.

3. *Pain* is not of great value, and may or may not be present. At first it is often diffuse, and afterwards becomes more localized, while the various reflected pains are occasionally complained of—a wound in the hepatic region accompanied with pain in the right shoulder; a wound in the lower costal region with pain and rigidity in the epigastrium, and that often without any involvement of the abdominal cavity.

4. *Tenderness* is a very constant and reliable sign. I do not refer to the zone of hyperaesthesia of the skin in a certain segmented area corresponding to the deep-seated injury, but to the tenderness elicited on moderate pressure over the injured viscous. It is necessary to exclude the muscular tenderness along the path of the wound and the contused area in its immediate vicinity. This tenderness will indicate the seat of the injured viscous, thus giving some idea as to what incision will best meet the requirements of the case.

5. *Rigidity*, or the absence of it, is often most misleading. I have seen a flaccid abdominal wall in a case of multiple perforations of the bowel. On the other hand, board-like rigidity is frequently met with in a purely parietal wound.

6. *The pulse* varies in rate; it increases directly with the gravity of the intraperitoneal lesion, and gives an important basis for prognosis.

7. *Vomiting* is usually present, but not necessarily. Thirst is a most distressing symptom.

X-ray localization affords the most useful guide to the diagnosis of penetrating wounds of the abdomen. Without it there must often be a large element of doubt. I always advise the radiologist to curtail his examination as far as possible, even to the neglect of foreign bodies situated

elsewhere in multiple wounding; and every effort should be made to keep the patient warm throughout the examination.

TREATMENT.

The cases on their arrival at a casualty clearing station may be classified for the purpose of treatment, according to their general condition and irrespective of the class of wound, as follows:

1. In a dying condition, when nothing can be done except to relieve pain and thirst.
2. Showing varied degrees of collapse, but capable of resuscitation.
3. In good condition and operable.

Pre-operative Treatment.

This principally consists in treatment for shock. It is usually necessary to begin by raising the body heat, and for this purpose the radiant electric bath is the best. Saline, two pints, with brandy, is given subcutaneously prior to and not during operation, as formerly practised. For extreme cases intravenous saline with 3 per cent. sodium bicarbonate has lately been recommended, and is apparently more effective. If pain is present to any extent morphine is given; rest and absolute quietness are essential.

When to Operate.

In my opinion operation should not be undertaken before the patient has recovered from shock. Two arguments may be put forward in favour of immediate operation: (a) Internal haemorrhage; (b) danger of delay allowing peritonitis to supervene. Against these, however, it may be stated that almost every case of severe intraperitoneal haemorrhage, on its arrival at a casualty clearing station, is either in a dying condition or suffering from an extreme degree of collapse and has for the time being ceased to bleed. Except when there is only one perforation no serious infection of the peritoneum from the small intestines takes place until the lapse of about six hours from the time of being wounded. It is therefore in the best interests of the patient to delay operation pending his recovery from the initial shock before subjecting him to the further shock of operation. Indeed, in cases suffering from shock and haemorrhage I have often waited six hours or more, taking the risk of further haemorrhage, with results that have justified my delay.

Provided the patient is warm, operation is done at once. Saline is given on the table during the operation. The anaesthetic now used is warm ether and oxygen given by Shipway's apparatus.

OPERATION.

I attach great importance to the element of shock, and in general manipulation endeavour in every way to avoid any aggravation of it. The first essential is speed: the prognosis of the case varies inversely as the length of the operation. If the operation is not completed inside one hour the prognosis is not good. To do this, very free access to the peritoneal cavity is necessary. Another difficult problem in war surgery is the maintenance of a constant warm temperature in the theatre. In winter the table should be kept warm, and draughts from doors opening direct to the open air must be avoided.

Incision.

The abdomen is opened by a paramedian or, in some cases, a transverse incision. The skin is covered with tetra towels wrung out of hot saline, and over these a sheet of oiled silk is placed. On opening the peritoneum, owing to the sudden relief of tension, in many cases bleeding commences again. It is therefore necessary to mop up any blood quickly, and to attend to the bleeding point first. A large abdominal swab is next placed into the pouch of Douglas, and a systematic search made for injuries; by this means alone maximum speed and efficiency are secured. The small intestine is examined first, and any perforation covered with gauze, clamped, and left outside the abdomen; uninjured gut is returned immediately, as far as possible. Wounds of the colon are then looked for and dealt with, or packed off and dealt with later through a separate incision if free access cannot be obtained by the original opening. In wounds of the stomach the anterior and posterior walls are examined, while those of the solid viscera can be felt.

TREATMENT OF HOLLOW VISCERA.

I have very little to add to what has already been written on this subject. When wounds of both the small and large gut are present I deal, if possible, with the large bowel first, and always discard soiled instruments and gloves before proceeding to repair the small gut. With regard to the respective advantages of the lateral and end-to-end anastomosis, I have experienced so few recoveries in these cases that I am not in a position to express a definite opinion. End-to-end union takes less time if done by a single invaginating suture, and this method obviates the need for a second layer, involving a further reduction of the lumen of the bowel.

Injuries of the colon do best if operated upon at the earliest possible moment, and as these cases are usually admitted in good condition, delay is seldom necessary for the treatment of shock. X-ray localization is invaluable as a guide both to diagnosis and to the subsequent transverse incision. This gives direct approach, and if the colon injury is uncomplicated the field of operation is localized; moreover, there is little handling of the small bowel or unnecessary soiling of the peritoneum, and a retroperitoneal wound can be dealt with at the same time. Colon wounds are always closed by suture if possible, and I usually risk the faecal fistula which occasionally follows suture and drainage, in preference to making an artificial anus.

WOUNDS OF THE SOLID VISCERA.

Owing to the inability of the solid organs in the abdomen to overcome sepsis, the question arises whether wounds of them ought to be treated by excision of the infected tissue and suture.

Liver.

In many of my cases the treatment has been conservative. Sometimes laparotomy has been done for progressive haemorrhage, and packing the wound with gauze. In a few cases where the missile was retained sepsis has supervened, causing death. If the missile is moderately large and when accessible, it is now removed by resecting a rib above the costal margin, usually including the wound of entrance, thereby obtaining direct approach. Certain superficial wounds allow of excision of the track, removal of the foreign body, and suture. Failing this, a thorough mechanical cleansing of the wound is carried out; a packing of gauze is inserted to stop fresh haemorrhage, and removed within twenty-four to forty-eight hours; the peritoneal cavity by this time is shut off, and Carrel-Dakin treatment is substituted.

Pancreas.

Wounds of this organ often occur with other abdominal injuries, so that the pancreatic wound is overlooked. In two cases I removed the missile from the body along with lacerated tissue, and sutured it up. Drainage was obtained through the transverse mesocolon, which had been previously anchored to the anterior abdominal wall. In another case good drainage was obtained through a wound of exit directly behind.

Kidney.

For exposure, the transverse kidney incision is used. If it is found necessary to deal with an intraperitoneal lesion as well, the line of incision is extended towards the middle line in front. Complete removal of the kidney is only done for gross destruction or torn vessels. Previously, in less severe cases, where an operation was warranted either for a retained foreign body or for haemorrhage, operative procedure was confined to removal of the missile and arrest of the bleeding by packing with gauze. Lately, with a view to minimizing sepsis, I have tried a more thorough operation, where only the body of the kidney was involved. Infected and damaged kidney was excised and the renal wound sutured, with drainage down to it. This has proved more satisfactory and can be carried out in the majority of the cases, the renal vessels being compressed by a rubber-guarded clamp throughout.

CLOSURE OF THE ABDOMEN.

Having dealt with the various intraperitoneal injuries the operation is completed by removing swabs and mopping up any fluid in the abdominal cavity with gauze wrung out of hot saline. Finally the incision is closed in layers.

The question of drainage is often raised. Should it be practised at all, and if so, what are the indications? I favour drainage in certain cases. The factors which influence my decision in any particular case are, primarily, the relative infectivity of the parts injured, and secondarily, the time which has elapsed since the wound was inflicted. In wounds of the small intestine operated on within twelve hours the abdomen may be closed with safety. As regards colon wounds, whenever possible I supply free drainage, usually by rubber dam, direct to the site of suture; in my series the majority were treated in this way. Retro-peritoneal wounds of the colon are always very freely drained.

The superficial wound is excised according to indications, no attempt having been made to enter the abdomen by enlarging it, a practice I avoid if possible. When the wound is in the back it is dealt with previous to performing laparotomy, as recommended by Marshall.

ABDOMINO-THORACIC INJURIES.

It is generally accepted that gunshot wounds including both the chest and abdomen have proved fatal in the large majority of cases. This state of affairs was not improved by the active surgical treatment undertaken earlier in the war; nor did treatment on conservative lines tend to give any better results. Recently, however, a different type of operation has yielded results which have encouraged me to persist in it.

Respiratory distress is the outstanding feature on admission. It is often so severe that immediate operation is out of the question. The patient is placed in a recumbent position, morphine is given for pain and restlessness, and, when the wound in the thorax is a blowing one, a few temporary skin sutures often bring a marked relief to the breathing. Time is allowed for shock to pass off and dyspnoea to diminish before operating.

Abdomino-thoracic wounds may be classified for the purpose of treatment into four types, as follows:

(1) *Where there are separate entrance wounds in the chest and abdomen.*

Provided the chest wound is not a blowing one, the abdomen is dealt with first, and only if the condition of the patient permits is the chest wound attended to.

(2) *On the left side with the entrance wound about the level of the sixth to the eighth rib, with a high up abdominal lesion.*

A few cases of this class do well on conservative treatment, especially where a rifle bullet has gone clean through antero-posteriorly or vice versa. What probably happens is that omentum protrudes through one or two small holes in the diaphragm and, becoming adherent, acts as a plug. Unfortunately the damage is often more extensive, and some idea of this may be gauged by considering the nature and position of the missile as shown by x rays and the appearance of the chest wound. If the metal has travelled down into the lower part of the abdomen it is treated as in (1). More often, however, the abdominal injury is limited to the upper abdomen, and it is for this type of case that I use a purely transdiaphragmatic route, because (a) it saves time; (b) access to the upper abdomen is much easier than by laparotomy; and (c) it avoids the combined laparotomy and thoracotomy, which is highly fatal.

Operation.—The chest wound, with all infected tissue, is completely excised and enlarged backwards and forwards until about five inches of the affected rib has been removed altogether. With fresh instruments the pleura is opened widely, the haemothorax swabbed dry, and the chest cavity protected by large abdominal swabs. Having placed a self-retaining retractor in the wound, the rent in the diaphragm is found and enlarged up to four or five inches. The abdominal injury is reached in this way, and, when it has been dealt with, gloves and soiled instruments are changed, and closure of the diaphragm is accomplished by a continuous suture of chromic gut. Next, the lung is examined, and, where necessary, treated according to present-day methods. Suture of the parietal pleura may present difficulty. When it cannot be sutured completely and a large gap is left, the lung is brought up and fixed by suture to the edges of the hole. This gives an airtight closure to the cavity, and also acts as a barrier to any superficial sepsis which may subsequently develop. Closure of the wound in layers completes the operation.

(3) *On the left side, with the wound of entrance below the eighth rib.*

In this type the abdominal condition is often much more serious. Frequently the chest escapes altogether, or is so slightly injured that it can be left out of consideration, in which case the abdomen is dealt with by laparotomy. When, however, both chest and abdomen require attention, the following operation can often be employed, bearing in mind the position of the missile: The chest is opened as described under (2), and the incision carried forward on to the abdominal wall. By prolonging the wound in the diaphragm the parietal peritoneum may be opened to any required extent. The chest condition is dealt with, and the pleural cavity shut off by suture of the diaphragm to the chest wall just above the wound. The intraperitoneal injury can then be treated and the incision closed.

(4) *When the Entrance Wound is on the Right Side.*

It is usually found that the metal having penetrated the diaphragm is lodged in the liver. If operation is indicated by the condition and size of the chest wound or the retention of a large foreign body, it is practically the same as for the left side. Having opened the pleural cavity the rent in the diaphragm is then sought for and the metal removed from the liver by passing a forceps down the track. When, as frequently happens, the diaphragm is pierced near its attachment, the operation is to suture the edges of the hole in the diaphragm to the parietal pleura, and so effect direct drainage of the liver track with a completely closed pleural cavity. If injury to the abdominal viscera is suspected it is treated as in (1).

Post-operative Complications and Treatment.

*Shock is the commonest and one of the most serious complications that may follow operation for penetrating abdominal wounds, and the means usually adopted to combat it are as described under pre-operative treatment, with the additional use of rectal saline, or brandy and coffee when the degree of collapse is not extreme; cases with severe shock derive very little benefit from this method as it is seldom absorbed. Much more useful is the intravenous injection of a solution of 4 per cent. sodium bicarbonate or a 2 per cent. solution of gum acacia in normal salt solution. But where the loss of blood has been severe blood transfusion is the best remedy.

The Fowler position is adopted as soon as the patient has got over the shock of operation, and for twenty-four to forty-eight hours rectal saline with glucose is given. Bland fluid is the only thing given by the mouth for the first few days. Early in the war I prescribed a purgative almost immediately after operation, but I discontinued that in favour of a glycerin enema with pituitrin hypodermically on the third day.

Dilatation of the Stomach.

This occurred in several cases; the chief symptoms were a feeling of tightness in the epigastrium, restlessness, and, in the beginning, the vomiting of a small quantity of dark brownish fluid. Relief is afforded if a stomach wash of sodium bicarbonate is done early.

Paralytic Ileus.

This condition may arise in two ways: (1) It may be nervous in origin—that is, there has been primary inhibition of the nervous mechanism in the bowel due to trauma (see Case 1 below); or (2) it may be secondary to peritonitis. The symptoms are almost identical, whatever the cause, and simulate those of progressive peritonitis.

In my earlier cases operations were done to prevent or alleviate this complication. In every instance quoted there was present some degree of peritonitis, and paralytic ileus seemed imminent. In two cases, having dealt with severe wounds of the lower part of the ileum by suture, a prophylactic anastomosis was made between the parts of the bowel above the injured area and the transverse colon. Both patients were suffering from shock at the end of the operation, and neither of them recovered. It is obvious that the operation was prolonged by the anastomosis, and in view of this delay I doubt whether I was well advised, but the prognosis in both cases was not good from the start.

In one case only, occurring in December, 1915, where the upper part of the ileum had to be sutured in nine places

over a length of three feet, a short circuit above and below the injured area was done. This case did remarkably well until the twelfth day, when peritonitis became marked in the short-circuited portion, and the patient subsequently died from general peritonitis. In deciding to perform this operation I was influenced by a desire to avoid the risk of resection.

In six others, comprising perforations sutured at various levels of the small intestine, ileostomy was performed—a large catheter or half-inch tubing was inserted several inches above the first perforation either at the original operation or secondary to it. This met with little success. I experienced great difficulty in getting the catheter to act, and when once started the intestinal drainage was very limited. Consequently the peritonitis was not stayed. Possibly the addition of a second catheter inserted below the last intestinal perforation would have given more encouraging results. Latterly, however, several bad cases of paralytic ileus have recovered, the treatment consisting of frequent gastric lavage, intramuscular injections of pituitrin, appropriate saline, and the administration of enemata as required. Morphine was not withheld.

Gas Gangrene.

In this series one case developed gas infection of the anterior abdominal wall in which the deep epigastric artery had been severed. As a precautionary measure, where the wound of the abdominal wall was extensive and had to be freely excised, the peritoneum alone was sutured and a few tension stitches of strong silk, protected by capillary tubing, were inserted. I am unable to state accurately the number of cases in which retroperitoneal sepsis—gaseous or non-gaseous—became a prominent feature, but in most of them it proved fatal. One bad case, however, recovered. In this case the gas had extended from one side to the other, lifting the peritoneum from the posterior abdominal wall. A very large incision was made, resembling that employed for exposing the ureter; infected and gangrenous muscle was removed; Carrel's tubes were placed in all directions and hourly injections of Dakin's solution given.

The following are notes on a few interesting cases.

CASE I.

Lce.-Cpl. S.; admitted February 12th, 1916. The missile had entered from behind at close range, explosive in action, carrying away a portion of the right rectus below the umbilicus; two feet of intestine lying on the abdominal wall. Bowel outside showed evidence of plastic peritonitis; four large holes in it and the mesentery torn; general condition fair. Laparotomy: Abdomen full of blood; no further bowel injury discovered; resection of two and a half feet with lateral anastomosis; abdomen closed without drainage; pulse 120. Twenty-four hours later: vomited a large amount of blackish fluid; under local anaesthesia a large catheter was inserted high up in the jejunum; stomach washed out. Second day, evening: About 5 oz. of yellowish odourless fluid came away. Third day: Catheter acting well after being syringed and siphoned with saline; patient felt and looked ever so much better. Fourth day, early morning: Catheter not draining, patient very ill indeed, looking moribund; catheter syringed out and siphoned; large quantity of foul-smelling fluid came away; improved beyond all expectation—pulse returned with good volume. This carried him through to the fourth night and he died in the morning. If the catheter was not siphoned every few hours he vomited, though very little. *Post mortem*: No evidence of peritonitis, serosa shiny, no adhesions even in pelvis or over anastomosis, bowel at and below the union collapsed—for two feet it contained a little fluid, while the last fourteen inches of the ileum was absolutely collapsed.

CASE II.

Pte. S.; admitted August 31st, 1916. Wound of entrance only, left groin; severe shock, pulse thready and of poor volume. Operation: Left paramedian incision; found twelve holes in the ileum and two in caecum, with considerable plastic peritonitis; resection of five feet with lateral anastomosis; holes in caecum sutured; foreign body removed and abdomen closed without drainage. Recovery. Base September 10th.

CASE III.

Pte. C.; admitted May 25th, 1916. Wound of entrance only, to the left and at the level of the umbilicus, omentum protruding. Operation: Right paramedian incision; enormous quantity of blood; eight holes in upper ileum, four of them necessitating a resection with end-to-end union; remainder sutured, abdomen swabbed dry and closed. Recovery. Base June 18th.

CASE IV.

Pte. F.; wounded March 7th, 1916, 11.30 p.m.; admitted March 8th, 8 a.m. A rifle bullet entered in the epigastric region and emerged at a corresponding point behind. Patient

cold, collapsed, and pulseless; abdomen distended, rigid, and motionless. At the end of seven hours' rest and treatment he began to rally. 5 p.m.: Pulse 150. Operation, 5.30 p.m.: Left median incision—abdomen full of blood; two holes in the liver and two in stomach, the missile having then passed through the tail of the pancreas and emerged as stated. Visceral wounds sutured, abdomen swabbed dry and closed. Exit wound enlarged and the pancreas drained from behind. March 9th, developed bronchitis. March 12th, death—acute bronchitis.

CASE V.

Private S.; wounded September 10th, 11 p.m. Cause, bayonet. Admitted 6.30 a.m. Wound of entrance only, in the left groin, deep to Poupart's ligament. Patient collapsed, pulse thready and irregular; abdomen distended, but very little rigidity or pain. After four hours' rest and warmth he improved wonderfully. Operation, 10.30 a.m.: Left paramedian incision—abdomen full of blood, external iliac vein severed, two holes in the ileum. Ligation of vein, perforations sutured, abdomen swabbed dry and closed. Recovery. Evacuated to base September 19th.

CASE VI.

Pte. A.; admitted April 10th, 1917. Entrance wound right buttock, exit below and to the left of the umbilicus. Operation: Right paramedian incision; fourteen holes in the ileum, two in caecum; eleven of them treated by suture, remainder necessitating a resection of fourteen inches with lateral anastomosis; peritonitis present; abdomen swabbed dry and closed. Recovery. Base April 22nd, 1917.

CASE VII.

Lce.-Cpl. B.; admitted March 31st, 1917. A large piece of shell fragment hit the abdominal wall, carrying away portion of the oblique muscles. Several feet of intestine lying on the abdominal wall with many perforations; a small amount of mucoid and faecal material stained the serosa of the bowel. General condition very bad, but responded well to treatment. After five hours' rest, operation. Original opening enlarged; plastic peritonitis and perforations confined to the prolapsed portion of bowel. Resection of three feet; end-to-end union by a single invaginating layer; peritoneum only closed, using a few tension stitches for the skin. Developed pneumonia. Recovery. Base April 24th, 1917.

CASE VIII.

Pte. S.; admitted April 28th, 1917. Wound of entrance only, left buttock; signs of much shock and loss of blood; pulse 130; rigidity and tenderness confined to the lower abdomen. After three and a half hours' rest, marked improvement. Operation: Left paramedian incision—abdomen full of blood; internal iliac vein perforated—clamped with forceps; one hole in ileum sutured; patient became very collapsed, so the abdomen was closed, with forceps left in position. Transfusion of blood by the sodium citrate method; left the table much improved. Four days later forceps removed. Recovery. Evacuated to base May 18th, 1917.

CASE IX.

This is one of interest, as it is the only case of recovery I have had with an abdominal patient admitted pulseless who remained so for many hours. Pte. H., wounded July 21st, 1917, 12 midnight. Shell fragment. Admitted July 22nd, 7 a.m. Entrance wound only, mid-abdomen. Complications: Penetrating wound of chest and multiple wounds of both legs. 10 a.m.: Intravenous saline with 4 per cent. sodium bicarbonate and glucose given. 1 p.m.: Pulse for the first time felt at wrist. 4 p.m.: Warmer, and much improved generally; pulse 150. 5 p.m.: Pulse of fair volume. Operation, 5.30 p.m.: Right paramedian incision—abdomen full of mucopurulent fluid; one perforation in ileum with missile lodged there; removed and hole closed; abdomen swabbed clean, and a pint of warm eusol left in it, with drainage down to pelvis; the incision closed in one layer. Subsequent treatment: Repeated stomach lavage, saline, pituitrin, etc. August 1st, second operation: Resection of rib for septic haemothorax. Evacuated to the base August 10th, in good general condition.

CASE X.

Spr. F.; admitted April 30th, 1917. Entrance wound epigastric region, no exit; in fair condition; pulse 120. Operation: Left paramedian incision—abdomen full of blood; two holes in the liver; two in stomach; coronary artery severed. Visceral wounds treated by suture, artery ligatured; foreign body removed from the body of the pancreas, lacerated tissue removed, wound sutured and drained through the transverse mesocolon; abdomen swabbed dry and closed. Developed a pancreatic fistula, which gradually got less daily. Evacuated to base May 16th, 1917.

CASE XI.

Pte. H.; admitted October 1st, 1917. Shell fragment entering left side over sixth rib in mid-axillary line, penetrating abdomen; large haemothorax; severe dyspnoea; general condition good. Operation: Trans-diaphragmatic route; five inches of rib resected after excision of wound; pleural opening enlarged and cavity swabbed dry; omentum seen protruding through rent in diaphragm—this opening freely enlarged and abdominal viscera examined. The only visceral wound was a hole in anterior stomach wall with foreign body embedded in it; treated. Diaphragm closed, wound of lung sutured, and incision closed. Recovery. Base October 12th, 1917.

CASE XII.

Pte. D.; admitted October 10th, 1917. Shell fragment; entrance wound only, over eighth rib, left side; abdomen penetrated; general condition good; severe dyspnoea. Operation: Trans-diaphragmatic route—rib resected and blood swabbed from thorax; omentum found protruding through a wound in the diaphragm, size of a half a crown—enlarged this opening and found injury to spleen and kidney; foreign body removed from kidney, the wound being excised and sutured—no treatment of spleen; diaphragm closed; sudden cardiac failure then necessitated massage of the heart, which responded immediately; operation completed. Recovery uneventful. Base October 20th.

CASE XIII.

Lieut.-Cpl. W.; admitted October 15th, 1917. Entrance wound close to spine, with exit wound at tenth rib in mid-axillary line, from which omentum protruded; patient badly shocked, but apparently had not lost much blood. After four hours' rest and treatment, operation: wound of exit (with omentum) excised and enlarged forwards and backwards; rib resected; wound laid widely open; rent in diaphragm sutured to chest wall above the wound; spleen found severely lacerated and therefore removed; no other visceral lesion present; wound closed. Died suddenly twenty-six hours later, when apparently doing well.

CASE XIV.

Gnr. G.; wounded October 26th, 1917. Shell fragment. On admission same day a large blowing wound in the chest wall at the level of the ninth rib, right side; x rays showed a very large foreign body in the liver. Operation: Trans-diaphragmatic route—rib resected, including excision of entrance wound; pleural opening further enlarged; blood removed from pleural cavity; foreign body removed from the liver through the rent in the diaphragm; edges of rent sutured to parietal pleura; wound of liver packed with gauze surrounded with rubber dam; rest of the wound carefully stitched. Following day, gauze removed and replaced by Carrel's tube. Dakin's solution used. Recovery. Base fourteen days later.

The table shows the results of 150 consecutive operations for penetrating wounds of the abdomen. As regards mortality, shock played the largest part, peritonitis was next in importance, and pulmonary complications accounted for several deaths.

Viscus Injured.	No. of Cases.	Recoveries.	Deaths.
Small intestine only: sutured ...	28	17	11
Small intestine only: resection ...	13	4	9
Small intestine and colon (2 resections of small intestine, 1 died)	28	16	12
Small intestine, colon, and stomach	1	0	1
Small intestine, colon, and liver (1 resection)	2	0	2
Small intestine, colon, and kidney...	1	0	1
Small intestine, colon, and bladder	1	0	1
Stomach	3	0	3
Stomach and liver	6	3	3
Stomach, liver, and pancreas ...	3	1	2
Stomach, colon, and kidney	1	0	1
Colon	10	5	5
Liver	14	6	8
Liver and colon	5	1	4
Spleen (2 splenectomies; both died)	6	3	3
Spleen and diaphragm	2	1	1
Spleen and kidney	1	1	0
<i>Abdomino-thoracic Wounds.</i>			
Thorax and diaphragm (missile in lesser sac, no visceral lesion)	1	0	1
Thorax, diaphragm, and stomach ...	2	2	0
Thorax, diaphragm, and spleen ...	1	0	1
Thorax, diaphragm, spleen, and kidney	1	1	0
Thorax, diaphragm, and liver (lung in two cases)	4	3	1
Kidney (3 nephrectomies, 1 death) ...	9	8	1
Intraperitoneal lesion, no viscus injured	5	4	1
Total	150	76	74

*I take this opportunity to express my gratitude to Surgeon-General Sir Anthony Bowly, K.C.M.G., for his encouragement and advice throughout this period. My best thanks are due to

Surgeon-General Cuthbert Wallace, C.M.G., and to Lieut.-Colonel H. Rogers, D.S.O., and Lieut.-Colonel W. D. Kelly, D.S.O., for permission to publish these cases.

SHELL WOUND OF THE PANCREAS CAUSING PANCREATIC PSEUDO-CYST.

BY

JOHN MORLEY, CH.M., F.R.C.S., CAPTAIN R.A.M.C.(T.),

HONORARY SURGEON, ANCOATS HOSPITAL AND MANCHESTER CHILDREN'S HOSPITAL; LECTURER IN CLINICAL ANATOMY, MANCHESTER UNIVERSITY.

GUNSHOT wounds of the pancreas are less frequent, or less frequently recognized, than those of any other of the abdominal viscera, hollow or solid. The relations of the pancreas with the aorta and inferior vena cava, to say nothing of such vessels as the splenic artery and vein, are so intimate that perforation of the gland by a projectile involves the gravest risk of an immediate and fatal intraperitoneal hæmorrhage, and but few cases are likely to survive the first few hours. Should a case escape this primary danger, peritonitis resulting from coincident perforation of the stomach or intestines will usually supervene, and will naturally tend to monopolize the surgeon's attention, should a laparotomy be performed.

The extensive literature concerning penetrating gunshot wounds of the abdomen that has arisen during the present war is remarkable for the rarity of cases of authenticated wounds of the pancreas. Thus Surgeon-General Cuthbert Wallace, in a total of 955 penetrating abdominal wounds, collected only 5 cases of wounds of the pancreas.¹ He remarks that there are no distinctive symptoms of these wounds, and mentions that the formation of Jordan Lloyd's pseudo-cysts, so frequent after civil contusions of the pancreas, has not been seen. Surgeon-General Sir G. H. Makins² states that wounds of the pancreas found during the performance of operations for intestinal injuries have usually proved fatal, while in the few cases in which apparent wounds of the pancreas have been seen at base hospitals it is difficult to exclude the possibility of a wound of the second or third part of the duodenum. He mentions one case, fatal on the eleventh day, in which *post mortem* a wound of the pancreas was found with fat necrosis of the omentum and mesentery, and two other probable cases which recovered but were not established as pancreatic lesions beyond doubt. Fraser and Drummond,³ in a series of 300 cases of perforating wounds of the abdomen, met with one case only involving the pancreas—a rifle bullet wound through the body of the gland, where recovery followed exploration and drainage.

The case described below, in which a penetrating shell fragment gave rise to a large collection of pancreatic juice in the lesser sac of the peritoneum, is not unique, for I have been able to find one reference to a similar case, which is reported in a Hungarian journal that is not accessible.⁴

Pte. M. was admitted to High Street Military Hospital, Manchester, under my care on August 14th, 1916, with the following history: He was hit in the back by a shell fragment on July 24th, three weeks before he came under my observation. Some aching pain in the epigastrium resulted, but there were no symptoms of peritonitis, and he was evacuated rapidly to England. After six days in a central hospital in Manchester he was considered well enough to be sent to an auxiliary hospital in the country. While in that hospital the aching pain in the epigastrium persisted, and a week before he came under my care it was noticed that a swelling had appeared in the epigastrium, and that he was rapidly losing flesh.

Condition on Admission.

He was thin and pale and the tongue was foul. The temperature was 99.4° F. and the pulse 100. There was an unhealed wound of entry in the back 1 in. to the right of the eleventh dorsal spine, and no wound of exit. In the centre of the epigastrium was an obvious swelling. It was large, tense, and rounded, and extended back to the left loin. It was dull on percussion and only moderately tender.

Operation.

The case was regarded as one of subphrenic abscess involving the lesser sac of peritoneum. Accordingly, under ether, a small vertical exploratory incision was made through the left rectus below the costal margin. On opening the peritoneum

the empty stomach was found to be flattened out over the front of a greatly distended lesser sac. This exploratory wound was therefore closed, and an incision was made in the back of the left loin immediately below the twelfth rib. On opening the lesser sac by this route four or five pints of clear fluid gushed out, followed by a little pus. On digital exploration of the lesser sac a fragment of the copper band of a shell, 1 in. in length, was found lying free in the cavity, and was easily removed. The loin wound was drained.

Captain G. E. Loveday, R.A.M.C.(T.), examined a specimen of the fluid and reported that it contained both trypsin and amylase.

After-History.

The patient made a somewhat slow recovery, and vomited for some ten days after operation. He then improved more rapidly, and after a change to an auxiliary hospital was discharged as fit for general service.

I am indebted to Colonel F. H. Westmacott, A.M.S., Officer Commanding 2nd Western General Hospital, for permission to record this case.]

THE TREATMENT OF INFECTED WAR WOUNDS BY MAGNESIUM SULPHATE.

BY

ALBERT E. MORISON, M.B., C.M., F.R.C.S. EDIN.,
SURGEON, SUNDERLAND RED CROSS HOSPITAL AND SUNDERLAND
WAR HOSPITAL.

CAPTAIN W. J. TULLOCH and I have recently¹ described the treatment of infected war wounds by a concentrated solution of magnesium sulphate. In these articles we claimed as advantages for this dressing:

- (a) Its cheapness, ease of application, and infrequent and painless renewal.
- (b) That it is not easily absorbed and therefore gives rise to no constitutional disturbances.
- (c) That it induces the growth of firm, compact, bright red granulations, interferes with the proteolytic activities of the discharges, and stimulates the growth of epithelium.
- (d) That the magnesium ion has a decided inhibitory action on the growth of at least two of the organisms commonly present—namely, streptococci and *B. coli*—has also a less evident effect on the development of staphylococci, and a slightly inhibitory action on the propagation of the *B. pyocyaneus*.

General Principles of Wound Treatment.

The ideal method of wound treatment in military surgery has yet, I think, to be found, but, in order to discover it and to make it efficient, certain general principles must be considered.

1. The application must be easily carried out and readily applied.
2. Once dressed, it should be possible to leave the wound untouched for some time—that is, until the patient can receive more individual attention, or for such a period that he can be transferred from the field ambulance or casualty clearing station to a base hospital in France or England (about one to seven days).
3. Its action during this period should be continuous, and it should from the first exercise a beneficial effect upon the wound, so that on arrival at the base hospital sepsis should be either abolished or so inhibited that the health of the patient has not deteriorated, and so that further treatment may not be prolonged by dealing with conditions which were preventable.
4. As a necessary corollary to these principles it follows that all special apparatus used for flushing wounds should be abolished, thereby saving much time and labour to the members of the surgical and nursing staffs and much discomfort to the patients; special splints for the immobilization of each fracture would be unnecessary, and a return made to the simpler and more easily applied apparatus in general use for fractures, because the first dressing applied to the wound could remain untouched for several days.

Stages of Wounds.

In dealing with these wounds the two important stages through which they pass are to be borne in mind:

1. *Processes of disintegration* are set up immediately on receipt of the injury. As a result of trauma the wound

passes through various stages of molar or molecular gangrene, the tissues which have had their vitality too seriously sapped die and are cast off, and in so doing they become a medium for the development and growth of organisms. Treatment applied to the wound at this stage should have as its object cleansing the wound, getting rid of the sloughs, limiting sepsis, and preventing the proteolytic activities of the wound exudate as much as possible. This stage requires attention in the field ambulances and casualty clearing stations soon after the receipt of the injury and often under disadvantageous circumstances. When large numbers are passing through the surgeon's hands and accommodation is limited it is impossible to treat them on ordinary lines so thoroughly as is desirable. All that may be possible is to apply some dressing which will protect the wounds and diminish the chances of infection until greater individual time and attention can be given to them further behind the firing line.

The important point to remember is that if this part of the treatment is not carried out early, and with great efficiency, this first stage in the process of repair will be prolonged and rendered more serious.

2. *The phenomena of repair*, which begin when the processes of disintegration have been completed. Any substance applied to wounds at this stage which may interfere with the living leucocytes and prevent their phagocytic activities is to be avoided, and only those selected which will have a prohibitive effect on the proteolytic processes, and stimulate epithelialization of the wound. When this stage has been reached the patients should have arrived at the base hospitals, where more individual attention can be given. It is now, however, rarely that patients are transferred to the hospitals in England in this state. It more commonly happens that Stage 1 in the treatment of their wounds has to be continued on their arrival, and the condition of the wounds, if not worse because of increased infection, is quite as bad as when they were inflicted some days previously; they are discharging pus freely, and bacteriological examination immediately on arrival in the hospitals in England as a rule shows that all the pyogenic organisms usually found in infected wounds are present in abundance. The treatment of war wounds, therefore, resolves itself into two stages: (1) the cleaning of the wounds, (2) the encouragement of healing.

Antiseptics, and especially pure carbolic acid, have a limited scope. They may arrest sepsis so long as the organisms have not gained an entrance into the deeper tissues—that is, they must be applied very early after the infliction of the wound; they prevent the formation of toxins, but at the same time so affect the vitality of the tissues that a further field is provided for the development of organisms for whose destruction they had been employed.

The most satisfactory method of treatment during this stage is the employment of some form of more or less constant lymph lavage, or continuous irrigation with fluids that will prevent the absorption of toxic products while not interfering with phagocytosis. It is on these lines that most of the recent treatment is based—for example, Wright's hypertonic (salt) solution, eusol, Carrel-Dakin method, etc. These methods of irrigation not only get rid of the discharge by flushing, but, what is of equal or more importance, the wound is allowed to remain open, or is enlarged to allow of the free escape of the products of disintegration and sepsis.

Magnesium Sulphate Cream.

During the past year we have been using in our wards a preparation of magnesium sulphate, made of the consistency of cream, as soon as the patients arrive in hospital. To make the conditions as closely as possible resemble those that exist in a casualty clearing station, about a hundred cases were dealt with as follows:

The dressings with which the patients arrived in hospital, most of which were applied from two to five days previously, were removed. A culture was taken by Dr. Helen Clark of the organisms—aerobic and anaerobic—present in smears from the wound, and without any preliminary cleansing of the wound itself or of surrounding parts; magnesium sulphate cream was then applied to the wound under a suitable dressing. The dressing was left untouched for from three to ten days. Bacteriological and clinical examination was then made of the discharges and

the wound. The results have been such as to encourage me to report the technique and results of this treatment.

The following cases, treated in one or other of the war hospitals in Sunderland, are typical of those submitted to this treatment.

CASE I.

J. McL.; gunshot wound of left leg, October 23rd; admitted November 6th, 1916. A large wound at the back of the calf, at the bottom of which a fracture of the tibia and fibula could be seen. This wound communicated with a smaller wound on the inner side. The temperature was 101.4° and the pulse 98. The wounds, which were dirty and discharging pus freely, were dressed with magnesium sulphate cream. On November 9th the temperature was 98.4°, and the wounds, which were then dressed, were much cleaner. On November 11th they were covered with bright red granulations. By December 4th the wounds were much smaller, the through opening had closed, and on December 20th the granulations were level with the surrounding skin.

CASE II.

J. B., aged 21; gunshot wound of left wrist. When admitted the left wrist and hand were swollen and there were two wounds, one over the lower end of the radius and the other in the palm close to the styloid process of the ulna. The edges of the first-named wound were ragged and necrotic and there was a purulent discharge. The temperature was 100.2°. X-ray examination showed a longitudinal fracture of the radius into the wrist-joint. The wounds were dressed with magnesium sulphate cream and an anterior splint applied. When dressed on November 15th there was a little serous discharge and the surface of the wound was covered with lymph, underneath which were healthy granulations. On November 21st the wound was covered with bright red granulations, and on January 4th, 1917, it was healed save for a sinus leading down to the necrosed bone, which was removed, under an anaesthetic, with a sharp spoon. On April 30th the wound was superficial and almost closed.

CASE III.

H.; gunshot wound of foot, October 22nd, 1916; admitted November 1st, with a lacerated wound midway between the two malleoli over the dorsum of the foot, extending inwards and downwards towards the scaphoid bone. The wound was discharging pus freely and the surrounding skin was swollen and red. Bubbles escaped on pressing the edges slightly. Bacteriological examination of the pus by Dr. Helen Clark showed *B. perfringens*, staphylococci, streptococci, and Gram-negative bacilli. X-ray examination showed a large foreign body in the scaphoid bone which was easily removed under a general anaesthetic. The cavity was cleaned with methylated spirit and dry gauze, and filled and dressed with magnesium sulphate cream. When dressed on November 11th it looked healthy, and the magnesium sulphate cream was reapplied. On November 20th there were only two granulating spots, and the wound, which had almost healed, was dressed with boric ointment.

CASE IV.

P.; gunshot wound of right foot, October 21st, 1916; admitted November 1st. The skin over the lower third of the leg was red and brawny and discoloured as high as the knee. There were two incisions about five inches long on the dorsum of the foot, and another along its outer border, which seemed to be an enlargement of an original wound in front of the external malleolus, which was packed with gauze. Behind the external malleolus was a deep lacerated wound with a small drainage tube. There was a copious discharge of foul pus from the wound track below and in front of the malleolus. There were two longitudinal incisions, one on each side, in front of the ankle and in front of the lower part of the leg. Bacteriological examination of the pus showed streptococci, staphylococci, and *B. coli*. X-ray examination showed a fracture of the astragalus and a foreign body lying in or internal to the bone. Under a general anaesthetic the wounds were cleaned, the foreign body removed, and the foot and leg dressed with magnesium sulphate cream. When dressed for the first time, seven days later, the dressed wounds were all looking healthy, but there was sloughing of the edges of the original wound and a good deal of sero-purulent discharge. On November 15th the wounds were all looking clean and were dressed again with magnesium sulphate cream. A superficial abscess on the outer side of the leg in its lower third was opened on November 22nd, mopped with dry gauze, and filled with magnesium sulphate cream. On December 20th an abscess was opened on the inner side of the foot and about 3 oz. of pus evacuated. The cavity was found to communicate under the tendo Achillis with the wound just behind the external malleolus. It was mopped out with dry gauze and filled with magnesium sulphate cream and closed with silk-worm gut. When dressed on January 1st, 1917, the wound looked healthy, and on January 12th all wounds on the outer side of the foot and leg were healed. Those on the inner side were closing rapidly. On January 22nd all wounds were healed.

CASE V.

G. R., aged 44; gunshot wound of right knee, April 9th, 1917. When he came under my care, on May 12th, the evening temperature varied between 102° and 104°, and he was complaining of great pain in the knee and sleeplessness. There were two through-and-through wounds on each side of the patella and two incised wounds above into each side of the subcutaneous pouch. In each wound there was a drainage tube. On that

day, under a general anaesthetic, a horseshoe incision was made round the patella dividing the ligamentum patellae. On opening the joint pus gushed out. The knee was bent to its full extent, washed out with ether, and filled with magnesium sulphate cream. Plentiful dressings of cotton-wool and sphagnum moss were applied. The wound was dressed every third day with magnesium sulphate cream until the 25th, when, his temperature having been normal for three days and the discharge having ceased to be purulent, the patient was again placed under an anaesthetic; the joint was then washed out with methylated spirit and bipped. The entire wound was sutured, the ligaments, including the patella, with catgut, and the skin with silk-worm gut. The patient's progress was uninterrupted, and he was discharged from the infirmary on September 14th, 1917, with his knee-joint movable about 15 degrees, and he was able to bear his full weight on the leg.

CASE VI.

C. L.; gunshot wound of back, October 28th. When admitted, on November 6th, 1916, there was a large gaping wound about six inches long over the left scapula, dividing the latissimus dorsi and partially the infraspinatus muscles. It was dirty and discharging pus freely. Magnesium sulphate cream was applied without previous washing of the wound. On November 12th, under an anaesthetic, the wound and surrounding skin were cleansed with petrol, the edges of the wound excised, and the refreshed margins undermined and brought together with silk-worm gut passed through pieces of drainage tube after the cavity had been filled with magnesium sulphate cream. When dressed, five days later, the wound looked healthy and the discharge was serous. On November 24th, when the sutures were removed, there was very little gaping and healthy granulations covered the linear margins. On December 18th the wound was soundly healed and the movements of the arm were good.

Preparation of Magnesium Sulphate Cream.

The cream is prepared in the following manner:

15 lb. of magnes. sulph. exsiccatum are mixed with 11 oz. of glycerin acid. carbolic, 1 to 10. The dried magnesium sulphate is in the form of a fine white powder, which contains 12 per cent. less water than the ordinary. The glycerin acid carbolic is put in a hot mortar and the sulphate added, slowly stirring and mixing with a warm pestle all the time. The result is a thick white cream, so hygroscopic that if exposed to the air it rapidly absorbs moisture and becomes dull. It must be preserved in a covered jar. The carbolic acid was first added for its analgesic properties, as it was thought that this application without it would be painful. We have found this precaution to be unnecessary, as the only discomfort of which the patients complain when carbolic is not present is that the cream feels cold for a short time after its application.

The wound is packed and thickly covered with the cream, and the dressing of gauze and cotton-wool is left unchanged for from three to eight days. A profuse discharge of serum takes place, so that more wool may have to be applied over and around the original dressing. On removing the dressings, any discharge there may be is sero-purulent, escapes easily, and the wound surface is covered with bright red granulations, filmed over by a thin layer of greyish lymph containing a few pus cells. A similar dressing is again applied spread thickly on gauze. In the case of deeper wounds, such as fractures, the cream is syringed into the deepest part of the wound by passing a piece of drainage tube attached to the syringe into it, and filling the wound with cream. More cream spread on gauze is applied to the surface of the wound.

After a few dressings in this manner, in the case of superficial wounds, a bright red granulating surface presents, covered by a greyish film of lymph. The dressing is now changed to magnesium sulphate solution for a few days, when the edges of the wound are either brought together with sutures, or skin grafts are applied under local anaesthesia.

In deeper wounds where a fracture is also present, after three or four applications of the cream, at intervals of three to four days, the patient is anaesthetized, the wound is freely opened up, loose pieces of bone are removed, it is washed out with ether or petrol, then dried with gauze mops and smeared thoroughly with bipp or X.Y.Z. paste.* The deeper layers of the wound are brought together with catgut sutures, and the skin edges with retention sutures of double bipped silk passed about 1 in. from the margin and tied over a dossil of gauze on each side spread with one or other paste. In some cases before the sutures are tied, the cavity is filled with magnesium sulphate cream. The sutures prevent a too rapid escape of the magnesium sulphate cream by osmosis.

The guides to closure of the wound are bacteriological findings of the discharge and the amount and clinical

* Xeroform, i.e., 10 parts tribromophenol, hydrarg. ammon., of each equal parts; paraffin, 1 pt., to make a paste.

nature of it. As soon as the bacteriologist reports a marked diminution in the number and character of the organisms present, and we find an almost complete absence of purulent discharge, the wound is closed. Bacteriological examination of the discharges is made from each dressing when it is removed, and I am indebted to Dr. Helen Clark, bacteriologist to the North-berland War Hospital, for her valuable assistance and help in this matter.

In a previous paper on magnesium sulphate solution it was claimed that this dressing produced firm, compact granulations, and also that rapid epithelialization of the wound took place under it. There is no doubt that under the concentrated magnesium sulphate cream the granulations are not so vascular and firm as with the concentrated watery solution, and moreover are covered by a layer of lymph, and that the epithelium from the edges of the wound does not close in so rapidly. This is what would be expected in an application which has so powerful an influence in controlling sepsis. Abscesses, if opened by a small incision, their pus contents evacuated, and cavity mopped out with gauze, filled with magnesium sulphate cream, and closed by sutures, generally heal with one or two dressings. Wounds, however, especially those of long standing, that have become sluggish do heal up under it. As would be expected in the presence of a preparation whose main claim is the production of profuse lymph lavage, these wounds do best which have no dependent counter-opening and which can be filled with the cream.

Conclusions.

Magnesium sulphate cream presents the following advantages:

1. Simplicity of application and the rapidity with which large numbers of cases can be dealt with—as in field ambulances and casualty clearing stations.
2. The infrequency of dressings, which even in the most septic cases need no change from three to eight days.
3. The combined osmotic action and the inhibitory effect on the growth and development of such ordinary organisms as are usually found in wounds—aërobic and anaërobic—together with its non-toxic action on the patient, make this a valuable dressing in the first stage of wound treatment, where the aim is to get rid of sphacelated tissue and minimize sepsis.
4. Its sphere of action as a rule ceases after the first stage, because epithelialization is inhibited and granulation tissue formation delayed as soon as the wound has been cleansed.
5. In the second stage of wound healing, that is, the encouragement of repair, other remedies should be employed, though it is useful with chronic sinuses or wounds which require stimulating.

POST-OPERATIVE THROMBOSIS AND EMBOLISM.

By CHARTERS J. SYMONDS, C.B., M.S.,
F.R.C.S.,

CONSULTING SURGEON, GUY'S HOSPITAL.

In a discussion some years ago at the Royal Medical and Chirurgical Society, upon the complications following appendicectomy, I called attention to a possible cause of embolism, and suggested a remedy. In view of the interesting communication from Dr. McCann (March 9th, p. 277) it may be worth while to recall some of the observations.

All will agree with the sound conclusions as to technique enforced by Dr. McCann, and it is, I expect, to improvements in this regard rather than to any detail in ligature that the diminished incidence of the complication is to be attributed. Once sepsis has begun, its spread would be encouraged by bruised tissue, which is a soil favourable to the growth of bacteria. Herein lies, I take it, the truth of Dr. McCann's theory. Careless division of vessels, leaving parts poorly nourished, will determine extension of sepsis in an amputation, but in this, as in the special field alluded to by Dr. McCann, the primary step is a certain

degree of sepsis introduced at the operation. That this may be an auto-infection cannot be altogether denied, and the experiments on *bistournage** by Chevalier give support to Dr. McCann's views. It will be remembered that, while a mild illness occurred in rats inoculated but not injured, those in which the spermatic cord was twisted all had gangrene at the site of injury and all died.

It is only on such a basis that we can explain the many cases of local phlegmon, of all degrees of intensity; the acute periostitis in young people resulting from a slight injury; and the acute psoriasis following a strain. It is an injury that determines a joint infection in septicaemia. During this war acute suppuration of the knee has been seen to follow the manipulation required to deal with a septic compound fracture of the femur, and again of the ankle-joint under similar conditions. One of the most tragic cases coming under my notice was that of a surgeon who had scratched his finger while operating on a septic case. The injured part healed in two or three days, and he was apparently quite well and discharging his duties. He reached up to pluck a flower, and felt a "rick" in his "shoulder"—that is, vaguely; it might have been in one of the muscles. Four hours later he had a rigor, and an acute phlegmon developed in the pectoralis minor, from which he nearly died. This was a true replica of Chevalier's experiment.

If there be these acute auto-infections, so there are the milder varieties, and however perfect our technique may be, it must occasionally happen that we operate upon a patient in apparent health, yet in whom a septic infection of the blood is present. So long as the infective agent is within the endothelial-lined vessels the individual is protected, and the blood ultimately deals with and destroys the bacteria or neutralizes the products of bacterial life. Once this endothelial barrier is broken, as in the instance above related, by a rupture of muscle fibre, the infective agent escapes, and multiplies in the bruised tissue, the small blood clot, and the unprotected normal tissues. While we must be very careful in admitting such an explanation—one altogether too comfortable to the surgeon—we cannot exclude the possibility of such an occurrence. The practice adopted by many of having the patient in bed and under observation for a few days before operation is a wise precaution, and fully justified in the light of such events.

It remains to consider whether we can adopt any means of limiting the extension of the thrombosis. The disaster has occurred chiefly where primary union has taken place, and where none of the ordinary clinical evidence of sepsis has been manifest. It is, however, just in mild phlebitis that the detachable clot is formed. Where a vigorous sepsis occurs, with even double thrombosis and oedema of the legs, the clot is adherent and not likely to be detached. Looking back on the course of a case where uninterrupted recovery has followed, say, a simple appendicectomy, with no disturbance of temperature or pulse worth recording, small changes in the general condition of the patient will be recalled. There has not been the romping recovery, the subnormal temperature, the strong relish for food, the alert mental outlook one is accustomed to see. Small evidences of a disordered organism may be recalled, too slight to be recorded by the thermometer, or to affect a change in pulse rate. The pulse lacks tension, the blood pressure is probably low, sleep is not sound and prolonged, the mind is easily tired, and other small departures from the normal can be recorded. Finally, the patient is moved to a sofa or sits up, and then the oedema of the foot and ankle is discovered. At one time I made it a rule to examine the upper part of the thigh, where oedema shows itself in the recumbent position, before allowing the patient to get up. More than once it has been present. It is well to do this when the slight symptoms mentioned are present in a case where the wound runs a normal course.

It is a common observation that post-operative pulmonary embolism is seen only in connexion with operations on the abdomen. The inguinal canal and scrotum, as well as the rectum, must be included in this region. After an operation for inguinal hernia in a lady, a severe embolic attack occurred, through which she struggled for twelve hours, with great dyspnoea, cardiac pain, and cyanosis. A second attack followed the next day, and from this she also recovered. After a radical cure for

* That is, sterilization by torsion of the spermatic cord.

hydrocele in a young man, there occurred the most severe attack I have seen ending by recovery. He was unconscious for several hours, with a flickering pulse and cyanosis. This patient had been about the ward for some days.

Has anyone seen a case occur after an operation above the diaphragm? Here much tissue is often included in the ligature, sepsis is common as in breast cases, and is inevitable in operations for removal of the tongue. Nor has the complication, I believe, been recorded in children after any kind of operation. The common feature in these two conditions is free movement. It is impossible to keep a child quiet: he will move his legs about, and turn on his side after an operation for acute appendicitis. It is in movement, I believe, that safety lies.

It is the common practice to adopt the dorsal position, with knee-pillow, after abdominal operations, and also after parturition. Looking upon this position as tending to slow the current, as possibly determining thrombosis, or at any rate its extension, I abandoned the method in all but grave cases of suppurative peritonitis. For many years no case of embolism has occurred in my practice, and this I have attributed to the free movement permitted. If the knee-pillow is not begun the patient never knows of the luxury; it is a luxury, and moreover encourages complete rest. Then the hips and knees are moved three times a day, and the patient is encouraged to turn on his side as soon as possible. He is made to lie quite flat in the bed for part of each day. Nurses looked horrified fifteen years or more ago when these directions were given, and even now it is difficult to get rid of the knee-pillow.

Is it necessary to keep the parturient woman on her back for days together? From my experience, after abdominal operations I am inclined to think early movement of the limbs and frequent changes of position would diminish the number of cases of embolism. The suggestion that movement of the body interferes with the success of abdominal operations of any kind, is disposed of by the fact that vigorous vomiting even for a couple of days seems to have no injurious effects, and no ordinary movements can produce as much disturbance of the parts as vomiting. It was this observation, indeed, that led me to abandon a recumbent position of the rigid sort.

Nor can the mere size of the veins explain the thrombosis and embolism. In the neck the internal jugular can be divided and ligatured with impunity. It is often exposed in septic areas, as are the large facial and lingual veins, and yet only once have I seen thrombosis extend into the subclavian, and that was because, after an extensive dissection for glands, I left the vein instead of resecting it. That the anatomical condition of the veins has probably a good deal to do with the occurrence is no doubt true. The veins are unsupported by muscle, and this mechanical check to extension is absent.

Again, the smaller veins running a straight course enter directly into large vessels, as, for example, the spermatic into the renal, and the infected clot is swept away by the strong current.

Summary.

1. Pulmonary embolism does not occur after operation above the diaphragm.
2. Nor in children.
3. The common factor in the after-treatment of these two examples is freedom of movement.
4. Usually after abdominal operations movement is restricted, the dorsal position is enforced, and the knee-pillow adopted.
5. It is suggested that this practice determines massive thrombosis by slowing circulation.
6. It is suggested that the above restrictions should be abandoned, together with the knee-pillow, and daily movement insisted upon.

THE faculties and schools of medicine in France had a total number of 10,045 students in 1914. In 1915 the number had fallen to 2,944, rising again to 3,263 in 1916 and to 3,375 in 1917. There were therefore 6,640 fewer in 1917 than in 1914. In 1914 there were 1,038 women students. In 1915 the number fell to 772, and in 1916 to 765, rising again to 822 in 1917. There were therefore 266 fewer women studying medicine in France than in 1914. In 1914 there were 1,421 foreign students. In 1915 the number was 625; in 1916, 539; and in 1917, 515.

Reports of Societies.

WAR NEUROSES.

Cinematograph Demonstration.

At a meeting of the Section of Neurology of the Royal Society of Medicine on March 12th, the President, Dr. R. PERCY SMITH, being in the chair, Major A. F. HURST, M.D., F.R.C.P., R.A.M.C., gave a cinematograph demonstration illustrating the essentials of treatment of soldiers and discharged soldiers suffering from functional nervous disorders. The series of films shown had been taken during the last nine months at the Royal Victoria Hospital, Netley, under the auspices of the Medical Research Committee, in order that a permanent record of some of the remarkable neuroses which had developed in soldiers should be obtained to form a part of the medical history of the war. At the same time they illustrated the development of methods of treatment pursued. A year ago the workers were satisfied if they taught a man admitted for hysterical paraplegia, which had already persisted for several months, to get about within a day or two of admission, but they realized that he would require several weeks of further treatment by re-education before he could walk normally. Increased experience had given them greater confidence, and they were now disappointed if they did not cure all cases of hysterical paralysis, contractures, speech defects, such as mutism, aphonia, and even stammering, and the tremors and tics, which were formerly regarded as incapable of rapid recovery, within twenty-four hours of admission, however long the symptoms had persisted before the men reached Netley. This was demonstrated in the slow but steady progress shown by the cinematographs of the early cases contrasted with the more recent films, which afforded actual records of complete recovery, in the course of an hour, from hysterical paraplegia which had lasted for several months. The one essential for success in dealing with hysterical cases was complete mutual confidence of patient and medical officer. From the moment the former entered the hospital he was made to realize that he would quickly get well. Hypnotism was no longer used, and very rarely such adjuncts of suggestion as electricity or etherization; the medical officers contented themselves with vigorous persuasion and manipulation, being convinced that it was greatly to the patient's advantage that he should feel that he had taken an intelligent part in his own cure and that there was nothing mysterious about the proceedings. The opinion was expressed that the men should be admitted direct from France into special county hospitals, with special medical officers, who knew how to create a true atmosphere of cure. Here, along with the neurasthenics and psychasthenics, they would quickly recover, by being given, when convalescent, healthy and interesting outdoor employment, instead of lounging about the wards and corridors of large general hospitals with no opportunity of taking exercise except in the streets. Most would eventually return to military duty, whilst the remainder would be discharged from the service after a few weeks or months, but never before they had recovered sufficiently to earn a living in some civil occupation of national importance.

Discussion.

Dr. E. G. FEARNSIDES said that there was no single system which might not be affected by a functional nervous disorder. The commonest mistakes were those in which diagnosis referred to muscles, nerves, joints, and the extremities, such as "myalgia," "rheumatism," "lumbago," "sciatica," "neuritis," "rheumatoid or osteo-arthritis," "trench feet," and "frost-bite." In many cases diagnoses of affections of the alimentary tract or pulmonary system were attached to patients whose real trouble was of psychological origin. The majority of patients diagnosed as suffering from "D.A.H." would be benefited by special treatment directed to the psycho-neurological aspect of their disabilities. Cases in which the diagnosis of organic diseases of the central or peripheral nervous system was made were much less frequent. Schemes for the distribution of soldiers or pensioners in houses, with isolated families, were impracticable, owing to the size of the problem; and, moreover, in such houses there was no

atmosphere of cure. Special hospitals were necessary, but under military conditions a man must be either doing military work of some kind or be in hospital, yet no person who had broken down with a functional nervous disorder was fit on the day he left secluded ward life to meet the difficulties of the everyday life of the soldier; the hospitals, therefore, must have grounds for treatment in the stages between hospital and duty. As patients might show evidence of disorder of other portions of the body, the hospital should not be too far from experts in other classes of disease and injury, nor too distant from a general military or large civil hospital. Military hospitals should be near a railway station or there would be difficulties in transport and conveyance both for patients and consulting staff. There were two great groups of these cases: (1) The passive suggestible hysteric who had shrunk into himself and developed fixed, circumscribed, obvious objective difficulties, and was usually best dealt with by a *force majeure* sent in as a stimulus from the external environment; and (2) the restless, discontented, hypersensitive psycho-neurasthenic, with his much less easily comprehended subjective worries, fears, and bothers, ego-centric and yet expansive when approached sympathetically, who, if treated in the manner adequate in the hysteric would not only not be cured, but rendered wellnigh incurable. Occupation of a useful kind was essential, such as needlework, mat-making, wood-carving for bed patients; for those who could go about, training in some occupation likely to be of use in after-life had provided the most stable recoveries. Instruction in workshops was a necessary part of treatment in those who were not returning to the fighting ranks, but for those whose civil and military work would in the future be out of doors work on the land should be provided. Entertainments, especially those with a competitive element in which the patients took part, generally increased the rate of recovery. Physical drill and gymnastic displays were useful. Much depended upon the training and previous experience of the medical officer. He must know each patient and must not have too many on his hands. In general, fifty patients would be a maximum. Modified psycho-analysis was useful; dreams might be helpful in diagnosis and in elucidating the divers problems of psychological origin with which the patient was faced. Suggestion of some sort was essential, whether used through strong faradism, by personal contact, or during hypnosis. Massage, electricity (high frequency, faradism, static breeze, etc.), baths (sinusoidal, *can courant*, hot and cold douches, etc.), radiant heat, remedial exercises, gymnastic exercises, and physical training, were useful but secondary adjuncts. It would be well that the military authorities should establish near the special hospitals repairing dépôts for the A.O.D., the A.S.C., the A.S.C.M.T., and R.E.'s, where the working capacity of men in special hospitals might be put to immediate useful national military work. At the same time such dépôts would be a means of training soldiers suffering from functional nervous disorder before transference to these specialist branches of the army. Dr. Fearnside gave an analysis of results of treatment at the Home of Recovery, Golders Green, for the five months between October 1st, 1917, and February 28th, 1918. The number of discharges was 186. Of these 24 were medically unsuitable, 12 resented treatment, 3 left for good family reasons, and 4 were disciplinary discharges, a total of 43. Of the remaining 143, 4 practically attained pre-war standard, 39 were fit for work, 53 returned to former employment, 33 went to new work, and 14 went to further training.

Captain E. D. ADRIAN, R.A.M.C., said that when considering treatment the psycho-neurasthenic must be regarded as a type apart from the hysteric. Of 1,000 patients who had passed through his hands at Aldershot, 70 per cent. had been psycho-neurasthenics. These men as a class were far more difficult to treat, and for them treatment had to be more protracted.

Dr. J. CHARLTON BRISCOE said that after discharge from military service the men should be followed up and given an inducement to work; at the time of their discharge from Golders Green most were not fit for full employment, but many had been interested in the employments offered there, and had applied for further training in carpentry, engineering, etc. When a man left institutional

life he should at once go back to active employment. Some scheme to ensure this happening in the case of every single individual patient was necessary.

Sir R. ARMSTRONG-JONES, Dr. HENRY HEAD, and Sir JAMES FOWLER also spoke, and Major HURST, in reply to various questions, said that under favourable conditions about 50 per cent. of the patients could return to military duty, and at the time of discharge the other half were fit to earn their living in ordinary civil life. There was a great need for some scheme by which patients could be given work directly they left hospital. Of the types he had seen at Netley the hysterics were the easier to treat; they formed about the same proportion as at Aldershot. More medical officers were required, and kindness and sympathy were needed. The medical officer must be the patient's friend. Some means should be devised to prevent patients, before appearing at medical boards, being subjected to long and tiring journeys, or they would then seem much more incapacitated for work than they really were. It was desirable that the medical officer who had treated a patient should be a member of any board appointed to estimate incapacity.

Reviews.

MALARIA IN MACEDONIA.

Two medical officers—Major W. G. WILLOUGHBY, R.A.M.C., T.F. (M.O.H. Eastbourne), and Captain LOUIS CASSIDY, R.A.M.C.—who have been serving in Macedonia, have produced a book, entitled *Antimalaria Work in Macedonia among British Troops*,¹ which, small as it is, is likely to become a classic in the literature of malaria, for, although later editions may appear, this first issue, as giving the point of view of men actually facing the difficulties during the first two years in Macedonia, will always retain historical value. We may say at once that the book is a very complete little treatise on the mode of dissemination of malaria, and of the measures which can be taken with an army in the field for its prevention. As such it will be of immense value to military medical officers who serve in malarious countries; and not to them alone, for it puts the matter so clearly and simply, but yet fully, that it will serve as a useful *vade mecum* to officers of combatant units, of the Royal Engineers, and of the Army Service Corps.

The natural characteristics of the part of Macedonia occupied by British troops conduce to malaria. At the foot of the mountains, which are traversed by many ravines and valleys, there are large plains through which the water from the hills finds its way to lakes and to the sea. In the ravines the watercourses, overhung with vegetation, are narrow, with frequent rocky pools, in which mosquito larvae are found. Moreover, in the dry season some of these streams may become very scanty, with many side pools for which there is no natural drainage. In the plains during the hot malaria months the stream beds are only partially filled with water, leaving pools and patches of stagnant water generally full of weeds and many weedy shallows. In addition there are lakes with large surrounding patches of marshy ground overgrown with rushes and reeds. There are also many village springs, and where the flow is constant all the year round the overflow forms semi-stagnant waterlogged areas. Wells are less common, but they also are infested with larvae. Owing to these natural characteristics of the country and to the great heat of the summer, mosquitos, both *culex* and *anopheles*, have no difficulty in maintaining themselves. The native inhabitants are probably all more or less carriers of the parasite, so that the mosquito has easy work in transmitting malaria. Its opportunities have been greatly increased by the large number of soldiers who suffered from the disease during 1916.

Attention is directed to the need for destroying the adult insect, both when hibernating and during the summer, when it infests the vegetation on the borders of streams and lakes, and also in buildings and dug-outs. For the destruction of mosquitos in such places fumigation

¹ *Antimalaria Work in Macedonia among British Troops*. By W. G. Willoughby, M.D., Major R.A.M.C.(T.F.), and Louis Cassidy, M.B., Captain R.A.M.C. 1918. London: H. K. Lewis. (crown 8vo, pp. 68. Price 3s. 6d. net.)

with sulphur (1 lb. to 500 cubic ft. of space), the burning of cresol, and spraying with 1 per cent. solution of formalin are advised. It seems certain that when precautions are neglected many men become infected in the dug-outs. The main attack must, of course, be on the larval stage, which lasts seven to ten days. Large lake marshes are extremely difficult to deal with, but something may be done by reducing the amount of vegetation and by oiling the parts near the shore where the larvae are mostly found. Pools and marshy ground left by the summer dwindling of rivers in the plains can be dealt with by digging drainage channels, but in the rocky bed of a torrent special difficulties are encountered. An instance is recorded in which a pond, a fertile source of mosquitos, was situated in marshy ground but itself in a saucer-like depression in the rock, which could not be drained without much blasting and was too large to be filled in. A 6 in. iron pipe siphon was fixed and the level of the water reduced by 4 ft., thus lessening the area of water to be treated with oil. Constant supervision is required, and the patrols should be trustworthy and intelligent men who can be depended upon to carry out instructions and to report defects.

When all is done the whole area occupied by troops cannot be rendered free from mosquitos and their larvae in the time and with the means at disposal, and consequently personal prophylaxis is necessary. Here the chief implement is the mosquito net, but it is useless unless kept in good repair and properly adjusted each night. Face nets are also recommended, but it appears to be difficult to get the nets, and afterwards to induce the men to use them properly. The prophylactic value of quinine in the doses given has proved incomplete and questionable. Men receiving at least ten grains of quinine sulphate in solution twice a week, and often up to ten grains daily for a long period, have been taken ill with malaria, primary and recurrent. The conclusion is that while quinine prophylaxis should still be employed, especially where other precautions are difficult, reliance should be placed infinitely more on the various methods of protecting men from the bite of the mosquito, of which the most effective is the elimination as far as possible of its breeding places in pools, marshes, and casual water in wells, tubs, and hoof prints.

NOTES ON BOOKS.

DR. CAMPBELL MACFIE'S brightly written book, *The Art of Keeping Well*,² is intended for the general public, and contains many common-sense maxims, especially as regards diet and exercise, set forth with a wealth of apt illustration. The author, who has had much experience in sanatorium work, insists that no ventilation is good unless it creates a perceptible movement of air or breeze to stimulate the skin. In some practical remarks on sleep many readers will be glad to find that there is no hygienic or moral merit in early rising, and they should take to heart the further statement that in children it may impair the growth both of body and mind. As an example of the author's happy knack of epigram, his dictum that probably the two main causes of constipation are unpunctuality and pills may be quoted. Like most books this one shows the influence of war conditions in some of the analogies, and in a reference to the erroneous belief that war bread is indigestible.

MM. COPPEZ and VAN LINT have written for nurses an eminently readable and very useful little book³ on the care of the eyes. Especially worthy of note is the profusion of illustrations, admirable reproductions of actual photographs. The first part of the book deals with the anatomy and examination of the eye, the second part with such matters as lavage, bandages, shades and goggles, lotions and drops, electrotherapy, ocular massage, and the application of heat and cold to the eye. The third part describes the hygiene of the sick-room, the operation room, the sterilization of instruments, and ophthalmic nursing before, during, and after the actual eye operation. The fourth part is devoted to certain special subjects, such as the nursing of purulent ophthalmia in the newborn and

first aid in accidents, burns, etc. There is an excellent chapter on prosthesis, and a glossary of the various ophthalmic drugs and instruments in common use completes the volume.

MEDICAL AND SURGICAL APPLIANCES.

An Amputation Flap Retractor.

CAPTAIN R. BUTE MACFIE, M.B., F.R.C.S.E., R.A.M.C. (I.C.), writes: The illustrations will give an idea of the construction of this instrument which I have designed. Its main objects are to give the maximum retraction of skin and muscle flaps in amputating and the easiest access to the bone to be divided. It is easily applied by one assistant, and, when the operator is dividing the bone

the assistant's hands are well out of the way—the bone can be divided without obstruction at the desired point. The diamond-shaped opening gives ready adjustment to any size of bone, and the whole is readily sterilizable in the army pattern sterilizer. This form of retractor has been used in several hospitals in France for eighteen months and has given satisfaction in every way. It is made by Messrs. Mayer and Meltzer.

ROYAL MEDICAL BENEVOLENT FUND.

THE annual general meeting of the Fund was held on March 12th, when the officers were re-elected. Votes of thanks were passed to the Editors of the *Lancet* and *BRITISH MEDICAL JOURNAL*, Mr. Guy Elliston (Financial Secretary of the British Medical Association), and to the lay press.

Owing to the growth of the work, a subcommittee has been appointed to deal with cases and to report to the Committee of Management in the same manner as another subcommittee reports on annuities. Reference was made to the loss the Committee had sustained by the death of Dr. Parker Young, who had been a member for forty years, and had served the Fund with great constancy and devotion. During the year Dr. W. S. Colman, Dr. John Fawcett, Mr. Guy Elliston, and Dr. Leonard Guthrie had been elected members of the Committee, and Dr. Newton Pitt had been appointed representative of the Royal Medical Benevolent Fund upon the Professional Classes War Relief Council. The report contained an expression of the view that disputes between the Fund and Epsom College with reference to legacies should be settled amicably, and of the hope that some means of referring such matters to arbitration would be found.

War Emergency Fund.

The report contained a brief explanation of the reasons for the establishment of the War Emergency Fund. It was started in 1916, and more recently a second appeal was made, which was supported by a letter addressed to members of the Association by the President, the Chairman of Representative Meetings, the Chairman of Council, and the Treasurer (*BRITISH MEDICAL JOURNAL*, December 22nd, 1917, p. 842). The report pointed out that many medical men, when called up, had to leave on very short notice, without time to make adequate provision for the continuance and maintenance of their practice during their absence. As a result they had to face a severe fall in income, even when supplemented by army pay, while many expenses, such as rent, insurance, taxes, family maintenance, and education, could not be materially reduced. Although in a year or two after their return it may be hoped that those affected will recover their position, still in the interval help is and will be required, and it is to meet these needs that the War Emergency Fund was instituted. To be effective the grants must be made on a liberal scale, and the fund from which they are

² *The Art of Keeping Well*. By Ronald Campbell Macfie, M.A., M.B., C.M., Honorary LL.D. Aberdeen. 1918. London: Cassell and Co., Ltd. (Pp. 244, with one colour and three half-tone plates. 6s. 8d.)

³ *Soins Oculaires à l'Usage des Infirmités*. By H. Coppez, Agrégé à l'Université libre de Bruxelles, and A. van Lint, Chef de Service à la Policlinique de Bruxelles. Brussels: O. de Rycker and Mendel. 1916. (Cr. 8vo, pp. 186; 114 figures.)

to be drawn must be a large one. The appeal is for the sum of £25,000. The following statement shows the response so far made:

	£	s.	d.
First appeal (1916)	3,892	2	2
Second appeal (1917-18):			
Received	£10,833	7	9
Promised	500	0	0
Dividends		247	5
	15,472	14	11
The investments in National War Securities amount to... ..	13,500	0	0

Hitherto the cases with which it has been called upon to deal have not been numerous and the amount actually expended is small. It was anticipated that this would be the case so long as the war lasts; when it is over and the medical men return to civil practice their army pay will cease and many will be hard put to it to meet necessary expenses while they are recovering their former position. Many of the cases already dealt with have been very hard; the help given has been most valuable and has most conclusively proved the need for such a fund. It is expected that the number of cases will become large when demobilization occurs, and the money not immediately required is being invested in War Loan. It is calculated that the whole amount in the Fund will be spent in the course of two years or so after the war ends. The money received by the Fund has so far been subscribed entirely by the medical profession itself, and it is felt that an appeal should be made to a wider circle. No profession has been so hard hit by the war as the medical, and no other has been called upon, as a profession, to give its services unreservedly, though often at very great personal sacrifice. The value of the services rendered is shown by the immunity from diseases which were formerly the scourge of armies in the field and by the success of modern medical and surgical methods.

The General Fund.

The finances of the General Fund are administered in two departments—grant and annuity. The total donations and subscriptions to the grant department in 1917 amounted to £2,713, an increase of £645 over the previous year; this included a legacy of 100 guineas left by Lieut.-Colonel Leahy. The amount distributed was £2,269, including £120 in war-time gifts at Christmas. The decrease is due to the fact that twelve of the new annuitants had for long received grants from the Fund. The income of the annuity department was £2,911, or £75 less than last year, but when income tax on dividends has been refunded the total income will be about £200 more. The amount distributed was £3,221, including Christmas gifts of £1 each to the annuitants, who number 161.

THE THERAPEUTIC VALUE OF RADIUM.

THE annual report for 1917 of the London Radium Institute differs from its predecessors inasmuch as in place of any detailed account of the 603 cases treated in that year it provides summaries arranged under various heads of the conclusions drawn from the experience of the six and a half years which have elapsed since the institution was founded. During that period 40,000 treatments have been given to nearly 5,000 patients, of whom about half were suffering from malignant disease (including rodent ulcer). Each section is illustrated by cases. It was not found practicable to state the later results of all the cases treated, and as an alternative it was decided to select from the after-histories of those patients who could be traced a series of cases of cancer and of sarcoma which were apparently cured, if the test of immunity for more than three years is held to justify that term. Some such test is the only one that can be applied, and three years is the period usually accepted by surgeons. We regret that the limitation of space prevents us from giving a detailed account of all these remarkable cases, but we understand that a copy of the report will be sent, post free, to any medical practitioner who will apply to the Secretary of the Radium Institute, 16, Riding House Street, Portland Place, W. 1. The report, which is the work of Mr. A. E. Hayward Pinch, F.R.C.S., medical superintendent, who acknowledges his indebtedness to the assistant medical superintendent (Dr. J. E. A. Lyubain),

opens with a reminder that in judging the results recorded it must be remembered that the policy of declining to treat operable cases of malignant disease, rodent ulcer alone excepted, has been rigidly followed, save only in those instances in which patients have absolutely declined to submit to operation.

Epitheliomata.

The after-results of radium treatment of epitheliomata of small size, and affecting glabrous surfaces, when taken at an early stage and before lymphatic infection is evident, have been encouraging, and it is considered that when patients decline to submit to removal by excision the treatment may justifiably be resorted to. The results with epitheliomata of mucous membranes (mouth, tongue, fauces, or oesophagus) have been disappointing. In the mouth disappearance or fibrosis of a small primary lesion may be obtained, but sooner or later lymphatic involvement occurs. In the oesophagus definite temporary improvement may be obtained, the stricture becoming more patent, so that the patient is able to swallow solid food for six or nine months, or even longer. Some patients treated for epitheliomata of the vulva and vaginal mucosa remained apparently well for many months.

Carcinoma of the Uterus.

The larger number by far of these cases presented themselves at a stage when the disease was very far advanced, so that there could be no hope of apparent cure; but arrest of hæmorrhage, diminution of discharge, healing of ulceration, lessening of induration and relief from pain, were almost invariably obtained. Some patients responded much more speedily and completely than others, but in almost every instance distinct benefit was observed, and the rate of progress of the disease greatly retarded.

CASE 1337.—A woman, aged 46, who had undergone two partial operations in September and October, 1913. She received radium treatment in December, 1913, and in January and March, 1914. The disease was arrested, and the patient rapidly regained health and strength. In January, 1918, her medical attendant reported that she was quite free from any recurrence of the carcinoma.

CASE 382.—A woman, aged 68, with extensive cervical and vaginal cancer, declared to be inoperable by the surgeon consulted. She received treatment in February, April, and October, 1913, and in March, 1914. Great local improvement ensued, and from March to the end of September, 1914, she was apparently quite well, but in October symptoms of kidney disease appeared, and she died of uræmia in January, 1916. There had been no recurrence of the local trouble.

CASE 5348.—A woman, aged 34, with inoperable carcinoma of the cervix. She was treated at intervals varying from two to six months, the last time in July, 1916. In February, 1918, her general condition was good; she had gained in weight and was equal to all her household duties. There was extensive fibrosis of the vaginal walls.

Carcinoma of the Rectum.

The results here were not constant or uniform, but in some instances growths regarded as inoperable were so much improved, their size and vascularity being so lessened and the degree of fixation so diminished, that they were removed, and the patients remained free from recurrence. This, however, has not frequently happened, and in the majority of cases the most that can be hoped is healing of ulceration, diminution of the rate of growth, checking of the hæmorrhage, and postponement of the date at which colostomy becomes imperative. The best results were obtained where the growth was annular, spongy, and situate in the upper half of the rectum. The plaque-like, infiltrating growth was not found so amenable.

CASE 225.—A man, aged 70, underwent excision of the rectum for malignant disease in 1901. A recurrence in April, 1912, was excised; a second recurrence in October, 1912, was declared inoperable. He then had a hard carcinomatous ulcer immediately inside the anal opening, with much surrounding induration. He received radium treatment in October and November, 1912; the ulceration healed, and the growth was replaced by fibrous tissue, which caused stricture necessitating occasional dilatation; the patient when last seen, in January, 1918, was in good general health.

CASE 35.—A man, aged 35, received radium treatment in October, 1911, for a large ulcerated carcinomatous growth in the lower half of the rectum, declared to be inoperable. The ulceration healed, and the growth became reduced in size and much less fixed. Early in December Kraske's operation was performed, and the patient was given a course of prophylactic irradiation. He made a good recovery, and the latest information,

in February, 1917, was that he was in perfect health and leading an active and busy life.

CASE 752 is another example of malignant growth of the rectum pronounced inoperable, but after radium treatment successfully submitted to operation. He died from granular kidney and nraemia about a year later, but there was no evidence of recurrence of malignant disease.

CASE 1997 was that of a woman, aged 40, with extensive inoperable cancer of the rectum. She received radium treatment in January, April, and October, 1916, and January, May, and November, 1917. When last seen, in January, 1918, the disease was apparently quiescent, and there had been no rectal haemorrhage since the previous August.

Carcinoma of the Bladder.

Inoperable cases tolerant of intravesical applications may be advised to undergo radium treatment, as sometimes apparent cure results. Definite improvement in the symptoms is usually evident in about three weeks, and in the most favourable cases healing of the ulcer, with the transformation of the carcinomatous material into a fibrous mass, takes place.

Carcinoma of the Breast.

Cases of carcinoma of the breast form the largest class applying to the Institute; all those in which operation was at all practicable were invariably advised to submit to operation, so that those treated were nearly all in an extremely advanced state with extensive lymphatic involvement. In some instances great improvement followed radium treatment, especially in cases in which the disease was chiefly superficial, and confined to the skin of the operation area and the axillary and supraclavicular glands. Superficial ulceration unaccompanied by much subjacent induration often healed rapidly and completely after a radium exposure of eighteen to twenty-four hours. If the deeper lymphatics are involved and the lungs, or any of the abdominal viscera affected, little can be looked for beyond possible retardation of the rate of growth and the prevention of extensive ulceration. Cases of atrophic scirrhus in patients over 60 years of age may be kept in check for an almost indefinite time by radium irradiation repeated every three or four months.

CASE 1125.—A woman, aged 47, underwent in July, 1911, amputation of the right breast, with clearance of the axilla; in June, 1913, there was recurrence in the axilla. She was treated with radium during February, 1914, and by April the induration which had been present in the right axilla and in the left supraclavicular fossa had disappeared. In January, 1918, she wrote that she was better than she had been for many years.

CASE 151.—A woman, aged 64, underwent Halsted's operation in June, 1911. There was recurrence in February, 1912. She received radium treatment in March and April, 1913, and in January and March, 1914. When last examined, in April, 1917, no indication of any malignant trouble could be detected.

CASE 854.—A woman, aged 51. Right breast removed May, 1912; recurrence in ear September, 1913. She first received radium treatment in November, 1913; it was repeated in February and April, 1914. When last examined, in January, 1918, no trace of the disease could be found.

CASE 5003.—A woman, aged 48. Excision of the right breast in 1906; clearance of the axilla in 1909 for glandular recurrence; several operations for nodules, the last in 1912. In 1913 there were multiple recurrences, and a further operation was declared impracticable. She received radium treatment in January, March, and April, 1914; when last examined, in October, 1917, no trace of the disease could be detected.

Sarcoma.

The results of radium treatment of sarcoma are said to be on the whole more satisfactory than those of any other form of malignant disease, with the exception of rodent ulcer. The treatment must be vigorous, the tumours being treated whenever practicable both by the insertion of emanation tubes and by external radiation. The best and most rapid results were obtained in lympho-sarcomata; the disappearance of the tumours when the dosage was correct is said to be little short of marvellous. Sarcoma of the tonsil and post-nasal space have responded extremely well. The response of periosteal sarcoma has been good, but not so uniform, though the percentage of recurrence has been slight and cases are recorded in which the patient remained free from any manifestation of the trouble for a period of more than four years. Melanotic sarcoma usually proved unamenable, but in one case of melanotic sarcoma of the choroid and in another of the skin of the

back complete disappearance of the primary growths was observed. The former case (a woman) has remained well for two years, but the latter (a male, 21) died fifteen months later from secondary deposits in the brain and lungs.

CASE 50.—A man, aged 41, treated for a large and rapidly growing recurrence of lympho-sarcoma of the neck. He received fourteen treatments from October, 1911, to January, 1912. The growth had disappeared at the end of February, and in January, 1917, the patient was seen free from recurrence, and in excellent health.

CASE 4931.—A woman, aged 32, with a large periosteal sarcoma of the right thigh, for which amputation at the hip-joint had been suggested. Microscopical examination showed that it was a spindle-celled sarcoma. She received radium treatment during February and April, 1914. Improvement was very rapid, and the patient at the date of the report was in excellent health.

CASE 567.—A woman, aged 62, with a large rapidly growing sarcoma of the clavicle. Radium treatment (June, 1913) was followed by rapid disappearance of the growth. When examined in January, 1918, there had been no recurrence.

CASE 4905.—A woman, aged 32, with rapidly growing recurrence of sarcoma of the nasopharynx. She received radium treatment in 1912, and at the last report (March, 1917) was in excellent health.

CASE 140.—A girl, aged 15, round-celled sarcoma of the superior maxilla with recurrent sarcoma following operation for a growth in the antrum. Radium treatment was begun in February, 1912; at the end of June all signs of recurrence had disappeared, and when last seen, in March, 1917, she was in excellent health.

Mediastinal Tumour.

Some remarkable results have been obtained in mediastinal tumours causing dyspnoea, venous congestion, and disturbance of the sympathetic and recurrent laryngeal nerves. It was considered probable that the majority of these growths were lympho-sarcomata, as this would account for the favourable influence that radium rays exerted upon them.

Lymphadenoma.

The response of lymphadenoma of recent origin, with enlargement of the spleen or mesenteric glands, to radium treatment may be rapid. In some cases, especially those treated in the early stages of the disease, the patients can go on for eighteen months or two years without further treatment, but the majority require the irradiation to be repeated at intervals of four to six months.

Rodent Ulcer.

Of rodent ulcer it is said that cases which have not received previous treatment with carbonic acid snow, ionization, or x rays, and in which the lesion does not exceed 3 to 4 cm. in diameter and does not implicate cartilage, bone, or mucous membrane, can almost invariably be cured by one or perhaps two exposures with powerful unscreened applicators. The tissues must be irradiated well beyond the margin as appreciable by sight or touch, and a long exposure given; otherwise recurrence will usually be noticed within twelve months. When the mucous membrane, more especially the nasal, is affected it appears almost impossible completely to eradicate the disease unless the area involved is very small. Advanced cases of old standing, with great destruction of the cheek, nose, and upper lip, involvement of the nasal mucous membrane, and perforation of the hard palate, could only be slightly benefited, but such severe cases, often seen during the first two or three years of the work of the Institute, have now become rare, probably because the efficiency of radium treatment of rodent ulcer in its early stages has been more widely recognized.

The report also contains a note upon the effect of radium in checking menorrhagia and metrorrhagia accompanying fibroid disease of the uterus. Among other conditions treated with greater or less success are to be mentioned papillomata of the bladder, lupus vulgaris and erythematosis, keloid, lichenification of the skin, pruritus, and naevi. When used in exophthalmic goitre radium may at first cause exacerbation of all the symptoms, but usually within six weeks or two months tachycardia lessens, the tremors diminish, the exophthalmos becomes less noticeable and the restlessness and irritability decrease.

British Medical Journal.

SATURDAY, MARCH 23RD, 1918.

MALARIA IN THE ARMIES.

MANY districts of Macedonia are notoriously malarious. Though no detailed statistics have been published it is known that the allied armies have suffered severely and that the mosquito hosts have upset many military plans, especially in the Struma Valley. That some of the delays and failures from this cause might have been obviated had the general staffs been better acquainted with the mode of dissemination of malaria and the measures necessary for its prevention or mitigation seems to be demonstrated by the fact that very considerable improvements were obtained last year. The casualty figures have been dwarfed by those of sickness due to malaria. The season at which the disease was most prevalent was from May to October. In the British army, in one region during January, about 1 man in 1,000 was evacuated weekly to the base with malaria. The number then rose steadily, until in the third week of May about 1 in 130 (about 7.6 in 1,000) had to be evacuated; then followed a slight remission, with a sudden rise towards the end of June, the figure reaching about 1 in 55 (about 18 in 1,000) in July, and continued about the same rate until September, when there was a slight fall. In mid-September there was a sudden rise, the maximum for the year being reached in the second week of October, when the rate was 33 in 1,000. Some specially exposed units, we are told, had almost, if not absolutely, all their personnel infected at the same time, and in a few cases as much as one-third of the strength of the unit has been evacuated to hospital within a month in the height of the malaria season. These figures, we understand, refer to 1917, when the continuous antimalarial work had resulted in a considerable diminution as compared with the previous year. Some rates issued by the War Office last July,¹ referring to a period of four weeks ending on June 23rd—not covering, that is to say, the season of the severest incidence—showed that primary cases of “malaria and other fevers” were 7.79 per 1,000 a week in 1916, and 5.56 in 1917. Had the recurrences been included the rates would have been very much higher. With regard to malaria in the French army in Macedonia, we published some figures last November showing that considerable improvement had taken place, which was attributed to the attention given to the sanitation of localities, to the free distribution of mosquito nets, and to the administration of a daily dose of quinine under supervision. The rate in August was 39.16 in 1916, and 23.8 in 1917; in September it was 74.6 in 1916, and 29 in 1917; only about one-sixth of the admissions in September, 1917, were new infections.

These high rates of sickness from malaria, coupled with the severe prevalence of dysentery and diarrhoea, embarrassed military operations. General Milne stated in his dispatch² that when in May, 1917, it was determined not to make a general attack, he found it necessary, moved by the experience of malaria and dysentery gained in the previous year, to abandon the forward positions on the right and centre of the line

and to retire to the foothills. It can hardly be doubted that the operations throughout have been hampered by the high rates of sickness.

That these misfortunes should have happened to the armies of France and Britain, the two countries which in friendly rivalry have solved the root problems of malaria—the nature of the infective agent and the mode of its dissemination—is one of those ironies of history which will lend point to the satire of some future Gibbon. The book by Major Willoughby and Captain Cassidy, reviewed elsewhere in this issue, provides ample material for judging the difficulties of the problem. The Intelligence Departments must have known that it would be impossible, having regard to the configuration and climate of Macedonia, to carry out a campaign in that country without incurring the risk of serious sickness from malaria. The country is infested with mosquitos, including several species of *Anopheles*, which find suitable breeding places not only in the marshy rivers of the plains, but in the valleys, ravines, and upland bogs of the hills. It was known, moreover, that malaria was endemic in Macedonia and that infected persons abounded among the natives. The conclusion that ought to have been drawn was that the mosquitos of the species capable of carrying the haematozoon would certainly be infested. To send large numbers of young soldiers into such a country without taking every precaution that science could suggest or experience dictate was a heinous military fault. We have no doubt that the risks were fully brought to the notice of the general officers commanding and their staffs by the respective medical departments, but there seems grounds for the belief that the full significance of these warnings was not appreciated. As the authors of the book to which we have referred say, “co-operation between officers of all branches of the army is far more satisfactory when its basis is intellectual.” Were the military importance of the problem fully appreciated, executive officers would be readier to consult with medical officers expert in malaria as to camp sites where these have not to be fixed by purely military exigencies. The medical department of the army, we are told, has too little executive power in many respects; mere recommendations lead to delay. The hibernating mosquito should receive special attention in the winter and spring months, and canalization and similar work should be begun early in the year, even in March or April, as soon as the waters begin to subside. Education of officers and men of all branches should be considerably extended, for it appears that insufficient notice is too often taken of lapses of care on the part of individuals in protecting themselves and others from exposure to needless risks of mosquito bites. One instance is mentioned in which at a night visit to a camp it was found that only 6 per cent. of the men had taken the trouble to close their nets properly. “The only censure in the case of which we heard was apportioned to the officer who made the discovery for not properly notifying his visit before examining the nets of the unit.” Clearly education is very much needed, and it is depressing to read that two medical officers newly arrived in Macedonia stated that attendance at lectures on malaria in their recent home R.A.M.C. training was optional. Macedonia is not the only malarious district in which the British armies are engaged. It is known that the incidence of the disease in Mesopotamia was severe, and if half of what rumour says can be believed the condition of things in East Africa is little, if at all, better.

¹ BRITISH MEDICAL JOURNAL, 1917, vol. ii, p. 56

The difficulties created for the army medical administration do not end when a malaria patient is invalided home. The number of men under treatment in this country has been very large, and we are afraid that no entirely satisfactory system of curing them has yet been evolved.

PROPHYLAXIS OF PNEUMOCOCCIC INFECTIONS.

THE black races are peculiarly susceptible to pneumococic infection; among the natives of Madagascar and Senegal and the Annamites virulent septicaemia with invasion of the serous membranes is prone to occur, and this tendency is aggravated when these natives are exposed to unusual conditions of cold. Jonin¹ has been impressed, from his experience at the colonial labourers' camp at Toulon, by the frequency of sudden death among these natives during the first few days of frank pneumonia; the heart was free from any murmur, but the pulse was rapid, and the systolic blood pressure often below 100 mm. Hg. In these cases the myocardium was degenerated, pericarditis and early pneumonia were present; death was ascribed to a toxic neuritis of the cardiac nerves, against which cardiac tonics and adrenalin are recommended. In the camps at St. Raphael and Fréjus the same tendency to septicaemia was shown, and among 52 cases of acute meningitis Banjean² reports 22 due to primary pneumococic infection—that is, not secondary to pneumonia; all ran a rapidly fatal course, were remarkably free from vomiting, and often showed pus in the accessory nasal sinuses; the cases occurred sporadically and not in an epidemic form. He also describes six interesting cases of pneumococic infection of the skin, four being on the face and suggesting erysipelas with oedema and great swelling. Small bullae then appeared in successive crops, and desquamation was sometimes followed by small yellow abscesses crammed with pneumococci.

In order to protect natives sent to France in labour contingents, the South African Institute for Medical Research provided a prophylactic vaccine, and the results of this immunization appear to have been very satisfactory, although as yet official figures are not available. This was but a small part of the extensive work carried out by F. S. Lister,³ under the South African Institute for Medical Research, on the immunization of man against pneumococic infection, and especially of the native mine labourers against lobar pneumonia. In America Douchez and Gillespie in 1913 established four main types of pneumococci,⁴ and shortly afterwards Lister began to isolate the groups in South Africa, and now refers to about a dozen, of which "A," "B," and "C" are responsible for 69 per cent. of cases of pneumonia there. It is interesting to note that group A, which is the predominant pneumococcus in the Transvaal natives, is not represented in America, and that groups "B" and "C" correspond to the American types II and I, which are the most important in the etiology of lobar pneumonia. A prophylactic vaccine of groups "A," "B," and "C" was given to large numbers of native mine labourers with most encouraging results; in the Crown mines the natives thus inoculated became absolutely immune to pneumonia due to these groups of pneumococci, though pneumonia due to these groups was prevalent among uninoculated natives

in other mines. But 82 cases of pneumonia occurred in the Crown mines among the inoculated natives; they were due to groups of pneumococci, mainly "E," "II," "J," "K," which are therefore probably of sufficient epidemiological importance to warrant their inclusion in a more comprehensive vaccine for future use. These observations are obviously not only of scientific interest, but of great economic importance. Apparently the results have met with some hostile criticism, and the suggestion has been made that the fall in the incidence of pneumonia among the inoculated natives is only part of the admitted decrease of pneumonia due to general causes.

Though these criticisms have only come to our notice in Lister's controversion of their validity, it certainly appears that he has a very strong case, and in any event his labours deserve sympathetic attention. After resorting in 1912 to Sir Almroth Wright's inoculation against pneumonia in the Rand mine labourers there was a remarkable fall in the mortality from pneumonia, but at that time the pneumococcus had not been classified into distinct groups, and it is therefore impossible to say what groups were prevalent in the pneumonia or were represented in the vaccine. Lister's work, therefore, constitutes what promises to be an advance in the practical and scientific application of vaccine therapy. It would be interesting to know what strains of pneumococci are responsible for pneumonia in this country, and how future specific protection by vaccine or curative treatment by antipneumococic vaccine will compare with the results in South Africa and in America respectively.

THE MINISTRY OF PENSIONS.

In seeking an explanation of Mr. Hodge's outburst at Worcester last Sunday we turned to the report of the War Cabinet for the year 1917—a new kind of Blue Book which seems to have greatly perturbed some of the old guard of the Liberal Party. We find there a section dealing with war pensions, covering the whole history of the Ministry which came into existence on December 22nd, 1916. Two main statements are made with regard to its work. The first is that the monetary scale of pensions has been increased and the conditions attached to them widened, so as to effect a more liberal recognition of the country's debt to its defenders. The estimated expenditure for 1918 is 23 millions, and for 1919, 41 millions and a half. But we gather that Mr. Hodge is of opinion that the allocations are in some respects inadequate; that he has had a severe conflict with the Treasury on the subject; and that it is now engaging the attention of the War Cabinet. The other statement in the Blue Book is that "the principle of compensation has been reinforced by that of restoration of social and industrial efficiency," and that the Ministry is concerned with "the continuing medical treatment of the discharged man, his education and equipment as a producer, and the avoidance of any feature in its code that would set a premium upon resigned helplessness or diminish the incentives to profitable exertion." Its obligation in this respect is set out in a later sentence, where it is stated that in the matter of after-care it "has established, and is still developing, extensive safeguards both for health and efficiency." The extensive safeguards enumerated are two: the first is an extension of an arrangement made through the National Insurance Commission for dealing with discharged sailors and soldiers suffering from tuberculosis and for medical treatment of the insured man, so as to provide medical and sanatorium benefits for all such invalided soldiers and sailors, whether insured or not, but subject in the case of the uninsured to an income limit of £160 a year. It is also stated

¹ Bull. Soc. de Path. Exot., Paris, 1917, x 774-7.

² Ibid., 816-827.

³ Publications of the Institute, edited by W. Watkins-Pitchford, M.D. (No. x.) Johannesburg, 1917.

⁴ BRITISH MEDICAL JOURNAL, January 12th, 1918, p. 57.

that, in cases where "special treatment beyond the competence of an ordinary practitioner" (the phrase of the insurance regulations) is necessary, an organization has been set up whereby the services of the nearest suitable hospital are utilized, the Ministry of Pensions defraying the cost. It is claimed also for the Ministry that it has co-operated with other authorities and with the Red Cross Society in enlarging the number of institutions available for the treatment of paraplegia, neurasthenia (including shell shock), epilepsy, and advanced tuberculosis. We are afraid that these phrases express intention rather than achievement. Recent statistics of local authorities show that large numbers of tuberculous men are awaiting admission to sanatoriums. With regard to paraplegia, we are under the impression that the Ministry has hitherto relied upon the Star and Garter Home, established at Richmond by private enterprise, and on provision on a similar basis in Scotland. The care of limbless men is stated in the report to offer the best illustration of the efforts made to combine medical treatment with industrial re-education, but here, again, we are under the impression that the system was in full working order in England, Wales, Scotland and Ireland before the Ministry came into existence. As to the enlargement of the number of institutions available for the treatment of neurasthenia, the only tangible information we have is contained in Mr. Hodge's onslaught on the Home of Recovery at Golders Green. Mr. Hodge committed himself to the opinion that to send men suffering from shell shock to this institution, which is within a raid area, was absurd, and to the further view that a system of hospitals for such cases only was not the best method of treatment. He wished neurasthenic cases mixed with others, "so that the chirpy cheery chaps would shed some of the sunshine of their presence on the neurasthenics." Mr. Hodge went on to say that he proposed to close the institution at Golders Green and to use it for entirely different purposes. The net result of Mr. Hodge's efforts to enlarge the number of institutions available for nervous cases would seem to be to diminish their number by one, yet from the statistics given by Dr. Fearnside (p. 346) it appears that of 143 cases treated to a conclusion at the Golders Green institution 66 per cent. returned to work and a further 24 per cent. were rendered fit for work. These results do not seem to support Mr. Hodge's view, and it may, indeed, be argued that if men are eventually to reside and work in London, or any other district exposed to air raids, it might not be a bad plan to let them complete their recovery in a home of recovery within such a district. We would, indeed, commend the whole trend of the discussion at the Neurological Section of the Royal Society of Medicine last week (reported at p. 345) to the attention of the Ministry of Pensions. It shows that, as in so many other instances, skilled treatment is the truest kindness. Another matter on which Mr. Hodge commented was that medical boards asked men what their work and wages were. Doctors, he said, had no right to ask such questions. It appears from the form for a medical report on an invalid that the doctor is only required to state the man's former trade or occupation. Mr. Hodge said that he hoped in the near future to have civilian boards for discharged men, and that doctors who asked such questions would have to answer to him. We believe that as things stand, men who on leaving hospital are not returned to their units, or to convalescent camps, or command dépôts, with a view of their returning to the fighting ranks, nor finally discharged from the army, may be sent to discharge dépôts, of which there are, we believe, five in England and Wales, one in Scotland, and one in Ireland. Here they are examined by one of two boards—a military board, which may discharge them from the army, when they pass directly into the sphere of the Ministry of Pensions; or they may be examined by a civilian board appointed by the Ministry of National Service, which may place them in one or the other of the low categories surplus to the establishment of the army. Such men will be available for civil work, but

the army will retain a call upon their services. As we go to press we receive a letter from Sir Matthew Nathan, secretary to the Ministry of Pensions, warning medical practitioners that if they attend pensioners, or the wives of serving soldiers, or widows whose husbands have been killed in the war, they do so at their own risk, and that the Ministry will not be liable for any charges which may be incurred. Such persons must in the first place ask the assistance of the local War Pensions Committee. The Ministry appears to have forgotten that the onset of an illness is sometimes acute. The Ministry of Pensions no doubt has a very difficult task, but we are not sure that it is tackling it in the right way from the medical point of view.

A PARSON-DOCTOR OF THE SEVENTEENTH CENTURY.

In his presidential address to the Medical Society of London¹ Mr. D'Arcy Power gave an account of John Ward, vicar of Shakespeare's native town in the seventeenth century. He graduated M.A. at Oxford in 1652. Although while at the university he was chiefly interested in chemistry, botany, and medicine, he never took the degree of Bachelor of Physic. It is probable that he was a student of medicine—a recognized status abolished at Oxford within Mr. Power's own recollection—and he seems to have treated sick persons. He left Oxford in 1660, and attended lectures on anatomy at Barbers' Hall, London. He thought of getting a bishop's licence to practise or the M.D. from a foreign university, but took orders instead, and in 1662 became vicar of Stratford-on-Avon, a living he held till his death in 1681. He left a diary, now in the possession of the Medical Society, which consists of a series of sixteen notebooks, extending from 1648, about a year after he entered the university, to 1679. At Oxford he lived in intimacy with members of the "Invisible College," out of which grew the Royal Society. As to the origin of that body he says: "I have heard this guess abt as ye ground of founding ye Royal Societie. The King well knew yt Harrington who wrote Oceana and such strange fellows as have had their discourses and meetings and have talked of a Commonwealth: whereupon he instituted another societie whereof his Royal Self vouchsafed to be one, in opposition to itt, not thinking fitt to put down ye other by open contradiction." The first volume of the diary contains notes of a Latin lecture on pleurisy, the urine, and menstruation. There are also extracts on the chemistry of antimony from the *Opera medico-chymica* of Angelo Sala, the first of the chemists who ceased to talk nonsense. Ward learnt botany from Bobart, the keeper of the Oxford Physic Garden; the structure of the body he studied in "Briggs, his *Anatomia*"; physick in Ramondaeus, translated by Tomlinson; and surgery in Paracelsus (Ambroise Paré), rendered into English by Johnson. Incidentally he mentions a case of hysterectomy: "Dr. Witherburne in London took out ye womb of a woman." From a note written in 1652 we learn that Glisson said that "Jolivius, one of his friends," stated that there was a kind of vessel distinct from the arteries, veins, and nerves, so connected throughout the whole body that their function was constantly to distribute a watery humour through the whole body. This statement was confirmed by Glisson in 1654. Jolivius, or George Joyliffe, after serving as a lieutenant in the Royalist army, studied physick and was incorporated doctor of physick at Cambridge in 1652. He never himself published his discovery, but the lymphatics were described by two other observers—Rudbeck, a Swede, in 1651, and Bartholinus in 1652. Ward assisted "Dick Lower" in some of his experimental work and was much under the influence of that famous anatomist. The notes relating to the practice of contemporary physicians show that medicine was not studied in the same scientific way

¹ Reprinted from the *Transactions*, vol. xl.

as anatomy and physiology. He relates how Thomas Willis, one of the leading investigators and physicians of that day, "imparts his receipts chiefly to two Apothecaries in Oxford." Of George Ent, to whom we owe the publication of Harvey's treatise, *De Generatione*, it is said that he was called to Warwick Castle, "my Lord Brook having a man very sick of ye griping of ye gutts, My Lord asked ye Dr. what was good for itt. He answered white wiue plentifully drank if itt was not too sharp would doe itt, hee would lay his life of itt." The result is not recorded. There are many references to George Bate, who at Oxford practised chiefly "among precise and puritanical people, hee was then taken to be one of their number." He moved to London and attended Cromwell in his last illness. At the Restoration he became physician to Charles II. Ward says he had heard that "Bate writt few bills wherein hee did not prescribe scurvy grass, hence some have styled him in my hearing, as relating itt for others, ye Scurvigras Dr., imaginiung, I suppose, there might be a tang of itt in most diseases." Mr. Power's address deals only with the first six volumes of Ward's MSS., but he hopes at some future time to give an account of the remainder. He says that the notes shew Ward to have been well read, clear in his opinions, with knowledge based on experiment, yet with a simple credulity inevitable in an age when scientific knowledge was so scanty and uncertain.

RETINAL DETACHMENTS IN RENAL RETINITIS.

FOSTER MOORE has shown that retinal detachment, though not common in renal retinitis, is yet not so uncommon as has been supposed. He has added¹ thirteen cases to those already published. The detachments are either flat or semi-globular, the former usually occurring in the central region, the latter in the periphery. He considers that they are dependent solely on the retinitis, which is generally of a severe type, and that they are independent of oedema of the rest of the body. The intraocular pressure remains within normal limits. Retinal detachment is especially frequent in the retinitis of pregnancy, and is usually bilateral. Nephritis does not cause detachment in the absence of retinitis. The liability to detachment is largely proportional to the severity of the retinal changes. The immediate cause of a detachment is an active subretinal exudation. If the patient recovers, reattachment of the retina occurs, but after recovery permanent visual defects remain, not due so much to the detachment as to the changes resulting in the central parts of the retina from the extensive and severe retinitis. The prognosis as to life is not modified by the existence of a retinal detachment. The paper is illustrated by some very beautiful photomicrographs of a preparation obtained *ost mortem*.

TRENCH FEVER AND THE LOUSE.

THE case against the louse is growing. The theory that it transmits the virus of typhus fever is now generally accepted; it has even been suggested that the virus, whatever its nature, passes through a stage in the louse, but this suggestion is not borne out by the fact that the fever may be directly communicated from one man to another by inoculation. The report of Sir David Bruce's committee on trench fever, which is published elsewhere, gives very strong grounds for believing that the infection of that disease is derived from the contents of the alimentary canal of the louse, since its excreta dusted on, or the crushed bodies rubbed into, a scarified surface induced an attack in six to eight days, while bites of lice from the same batches did not cause infection. The observations rather suggest that the infective agent may be an animal parasite, and as a mere guess the possibility that it is a haemogregarine may be thrown out. An organism of this genus, by which the Indian field rat is infested, passes one stage of its existence in a louse—*Haematopinus stephensi*.

A MINISTRY OF HEALTH BILL.

It is understood, writes our lobby correspondent, that the draft of a bill for establishing a Ministry of Health is ready for consideration by the War Cabinet, if, indeed, it has not already been submitted to them. The framing of the measure follows upon the conferences which Dr. Addison, Minister of Reconstruction, has had with various departments and parties affected. Nearly a fortnight ago he announced that agreement had been reached, and encouraged the hope that legislation would be obtained this session. Mr. Bonar Law, replying to a question in the House last week, stated that those concerned with the matter were sanguine that a scheme could be carried through, but he was careful to say that they were sanguine and not to suggest that he was. There is ground for the inference that he is not. Apart from the merits of the bill, whatever they may be, the question of time must weigh seriously in the mind of Mr. Law, as leader of the House. The Government resolved a long while ago that, subject to contingencies, the session should be made as short as possible, more especially because the new Register of Electorate will be available in the late autumn, and it is only right, whether or not there be a dissolution then, that parliamentary work should be rounded off so as to allow of a free decision as to a General Election according to the circumstances of the war. If a bill is to be passed this session, therefore, it must go through practically as an agreed measure, for even so, the detailed examination of the clauses in Committee and on Report would take some little time. The fact that so many persons have been consulted in regard to the drafting of the scheme has led to gossip in the lobby in reference to its provisions. It appears significant that amongst those who are in closest touch with the Insurance Commission the proposals find the least sympathy. The deduction is that between the rival claims of the Local Government Board and the Insurance Commission for place in the fresh constitution, the first named (in so far as it is at present concerned with health) has received greater recognition. Generally, however, the measure is spoken of as a compromise, not going very far at first, and the suggestion is made that it may excite criticism on that account quite as much as if it were comprehensive and definitive. The *Times* of March 21st stated that at a private meeting with Welsh members Dr. Addison said that the bill would probably be introduced immediately after the Easter recess.

THE QUEEN has appointed Sir John Phillips, M.D., to be honorary physician to Her Majesty.

THE Editor of the *Lancet* and the Editor of the *British Medical Journal* have been elected, at the annual meeting of the Royal Medical Benevolent Fund, Vice-Presidents of the Fund, in recognition of assistance given to the work of the affiliated War Emergency Fund.

Medical Notes in Parliament.

The Education Bill.

THE Education Bill obtained its second reading on March 18th. The debate began on March 13th, and in its course Mr. Peto presented the objection raised by the British Medical Association to Clauses 18 and 19 as introducing fresh complications in an already very complicated state of affairs with regard to the inspection and attendance on children under existing Acts. No fewer than nine different professional men might be attending a single family under different Acts of Parliament. Most boys between 16 and 18 years of age would be insured persons, and the bill would not only introduce a fresh complication and an overlapping with the health provisions of the Insurance Act, but would be a positive barrier to dealing with the whole of the question of the health of the people on broad and

comprehensive lines. Sir Henry Hibbert said that the medical grant regulations of the Board specified that if the school medical service was adequate and efficient the grant was to be at the rate of one-half of the expenditure. Lancashire had never received more than 40 per cent., because the Department alleged that no comprehensive treatment scheme was in operation, but it was infinitely more difficult in a county area than in a county borough to have a comprehensive medical scheme. In the year ended March 31st, 1915, the expenditure of Lancashire on medical inspection was over £11,000, and the grant £4,166, or 37.85 per cent. The Board refused to take into account any payment to an absent officer in excess of an amount equivalent to his ordinary naval or military pay. The Lancashire Committee in the early stages of the war offered to their officials—of whom they employed nearly 300—that if they would join the forces they would be given their full salary minus one shilling a day because most of them joined as privates. When the full salary was charged to the grant it was immediately objected to. In the resumed debate, on March 18th, Sir Philip Magnus also referred to Clause 15, urging that it was questionable whether the arrangements suggested in the bill were best calculated to secure good physical development or careful and sympathetic treatment during illness. Possibly such arrangements as were now suggested in this bill should be regarded as provisional only, until a Ministry of Health was appointed. Sir William Collins, referring to the physical welfare portion of the bill, gave his support to most of the changes it contained. He considered that the institution of camps, gymnasia, and swimming baths was all to the good, but medical inspection and treatment were to be spread over a much larger area as they were to be applied to secondary schools, and very large considerations would come under review. Some consideration would have to be paid to the representations of the British Medical Association. All questions of medical inspection and treatment would have to be reconsidered in the light of any proposal for a Ministry of Health.

Royal Air Medical Service.—In reply to Major David Davies, who asked what steps were being taken to expedite the transference of R.A.M.C. officers previously attached to the Royal Flying Corps to the Air Force, Major Baird said that the Medical Administrative Committee had met and had come to a number of decisions which were now being dealt with by the Air Council. The officers referred to would, in the first instance, be lent to the air force and would be under the direct control of the Medical Administrator. When the conditions of service for medical officers who were to be seconded to the air force had been decided, those officers who were considered suitable would be seconded to the air force.

Artificial Limbs for Officers.—Colonel Ashley asked why officers were not supplied with a new artificial leg when one was needed, as was done in the case of non-commissioned officers and men. Mr. Hodge said, in reply, that an officer of the army who had lost a leg was fitted with an artificial one free of cost, and was given a wound pension of £100 a year, out of which he was expected to defray the expense of repair and renewal. The wound pension was in addition to retired pay, so that actually no officer who had lost a leg in action got less, in the aggregate, than £150 a year. The question whether it was possible to give military officers further assistance in the matter of artificial limbs was engaging his attention.

Pensioned Soldiers Readmitted to Hospital.—Mr. Macpherson, in a written answer to Mr. Alden, has stated that cases of facial injury in soldiers who received pensions were at present being readmitted to military hospitals. Certain other cases of a special nature were readmitted when the nature of the injury rendered their treatment in a military hospital absolutely necessary in view of the urgency of the particular case.

Maternity and Child Welfare Bill.—This bill, defined as a measure to "make further provision for the health of mothers and young children," was introduced by the President of the Local Government Board on March 14th. It is a bill for England and Wales, and applies to the council of any county or county borough, the common council of the City of London, the council of any metropolitan borough, and the council of any borough or urban district having a population of over 20,000. Power is taken to add to the list the council of any county district. Any of these local authorities may make arrangements, subject to the sanction of the Local Government Board, for attending to the health of expectant mothers and nursing mothers, and of children under five years of age, not attending schools recognized by the Board of Education. There is a proviso that nothing in the Act shall authorize the establishment by any local authority of a general domiciliary service by medical practitioners. A second clause provides that every council in England and Wales exercising powers under this Act or under Section 2 of the Notification of Births (Extension) Act, 1915, shall establish a maternity and child welfare committee, and that all powers of the council under either Act shall stand

referred to this committee, which is to consist, as to two-thirds, of members of the council, and as to the remainder, of persons qualified by training or experience in subjects relating to health and maternity; women and members of the Insurance Committees concerned must be included.

Maternity and Child Welfare in Ireland.—Mr. Duke, in reply to Mr. Scanlan, said that arrangements for maternity and child welfare, in pursuance of the Notification of Births (Extension) Act, 1915, had been undertaken by the local authorities of twenty-six urban districts (including the county boroughs of Dublin, Belfast, Londonderry, and Waterford) and of two rural districts, and comprised schemes of health visiting of mothers and young children by duly qualified nurses, provision of medical and midwifery attendance in necessitous cases of confinement not otherwise provided for, the institution of maternity centres and day nurseries, and the supply of milk and dimmers for necessitous mothers and young children. An Exchequer grant was available to defray half the cost, and in the current financial year was being distributed by the Local Government Board to twenty-four local authorities and to twenty-eight voluntary agencies administering approved schemes. Further schemes on similar lines were being formulated.

Maisons Tolérées in France.—In reply to Mr. Lees Smith, Mr. Macpherson said, on March 19th, that it had been decided, with the permission of our allies, to put *maisons tolérées* in France out of bounds for our soldiers. He added that it was not the British authorities, as had been asserted, who established these houses or who provided the women in them, nor could he find any justification for the assertion that any part of the French civil population protested against any of these institutions established under their own laws; nor did our military authorities in France receive any such protest. Though this statement had been taken the House must not think that the very grave problems of venereal disease which confronted the military authorities in France had been disposed of. Military advisers had grave doubts that the contrary might not be the effect. The question, which it must be remembered was not merely a military one, but a great social and national question, would continue to be watched with anxiety by the War Office. Brigadier-General McMahon asked whether the decision had been come to without the concurrence of the military authorities. Mr. Macpherson replied that it had been come to with the concurrence of our allies. Mr. Gulland asked what was the punishment for being out of bounds. Mr. Macpherson said that one great effect of the new order was to add to the many punishments which were inflicted under the Army Act.

THE WAR.

TRANSMISSION OF TRENCH FEVER BY THE LOUSE.

A COMMITTEE for the study of trench fever, with Major-General Sir David Bruce, K.C.B., M.D., F.R.S., as chairman, was appointed last December by the Director-General, Sir Alfred Keogh, G.C.B., acting on a suggestion received from France regarding the co-ordination of research on this most important subject.

The committee at once set itself to try to solve the problem of the causation and spread of the disease, and has now presented the following interim report.

Method.

In view of the already widespread belief that the body louse was the guilty agent steps were at once taken to feed lice bred from "clean stock" on trench fever patients, of whom there were at the time many in the new end section of the Hampstead Military Hospital under the charge of Major W. Byam, R.A.M.C., a member of the committee, who has supervised the clinical and experimental work. The committee was fortunate in having Mr. Bacot of the Lister Institute to control the supply and feeding of the lice.

Experiments with Living Infected Lice: Negative.

Two volunteers, Messrs. Cole and Edgeler, came forward on January 3rd, 1918, for the purpose of the experiment from patriotic motives, as they were well over military age and not able to serve their country in more strenuous ways. Lice were taken from clean stock bred in this country. These lice were fed at intervals on many febrile and afebrile trench fever patients, at all stages of the disease, who had been sent over from France and had relapsed in this country. The lice were then placed on the volunteers, directly on the skin without any intervening gauze, the shortest interval between feeding on a case of trench fever and on the volunteer being six hours. After feeding they were returned to the box and kept in the incubator at 25° C. until again required. This experiment was commenced on January 5th, and was continued

daily for one month, at least 500 lice being used every day. The feeding experiment in one of the men was then discontinued, and although he has now been under observation for over two months he has shown no signs of fever.

The experiment was continued on the other man, but the conditions were altered: lice were fed on febrile cases of trench fever, and then after intervals of, at one time, fifteen minutes, at another of one hour and two hours, on the volunteer daily up to February 13th, but again without any positive results as regards development of trench fever.

Experiments with Excreta and Crushed Bodies of Infected Lice on Raw Surfaces: Positive.

At the committee meeting on January 23th, Major Byam, in reply to a question, stated that these men did not scratch themselves, and, indeed, purposely refrained from scratching, this excluding to a large extent infection by means of excreta or crushed bodies of the lice: he therefore proposed that two more volunteers should be obtained and "scarification" experiments carried out.

On February 5th two men, Seymour and Sullivan, who also volunteered, were used for this purpose. In the case of Sullivan a small area of skin, one inch square, was slightly scarified, and a small quantity of the dried excreta taken from the boxes of lice which had fed on trench fever cases was dusted on this area and rubbed in. On Seymour's arm eleven lice taken from a trench fever case were crushed on the scarified area. On February 14th Sullivan was suddenly attacked with typical trench fever after an incubation period of eight days. On February 16th Seymour also went down with fever (incubation period ten days).

This dramatic result was at once (February 19th) reported to the Director-General, Army Medical Service, and also to the Medical Investigation Committee in France, with whom the committee had been in close collaboration throughout, all minutes and results of experiments having been forwarded; in addition, Lieutenant Peacock, R.A.M.C., who had assisted Mr. Bacot in the earlier work here, was sent to the Medical Investigation Committee on January 24th to assist in the same work in France. The fever which these men Sullivan and Seymour developed was indistinguishable from that produced in other volunteers by an injection of whole blood from trench fever cases who had contracted their disease in France. In view of the importance of this discovery the committee decided to repeat the same experiment.

Three other volunteers at once came forward—Messrs. Reynolds, Tullett, and Glover. These men were each inoculated on February 19th on a scarified spot on the forearm with a small quantity of dried excreta from boxes of lice fed on trench fever cases.

On February 26th Reynolds went down with trench fever. On February 27th Tullett was taken ill, and on February 28th Glover; the incubation periods being six, seven, and eight days respectively.

The chain of evidence was completed by the fact that a small quantity of blood taken from Reynolds on the second day of his fever, and inoculated into another volunteer (Ward), produced a typical attack of trench fever after an incubation period of five days.

The fever in every instance, although mild, was yet typical of the so-called trench fever—sudden onset, temperature of 103° F., pain in the head and limbs, and over the spleen, the initial attack of fever lasting two or three days, and followed in practically every case by a relapse or relapses at an interval of usually seven days; the fever in the relapse being lower and more transient, with a recurrence of the symptoms associated with the initial attack.

Conclusions from Experiments.

It will thus be seen, from the above experiments, that it has been shown that the bite alone of the infected louse does not produce trench fever, but that when the excreta taken from such lice are scratched into the skin fever followed in every instance, the average incubation period being eight days.

This observation is of great importance in view of the prevention of the disease, and would explain cases of trench fever arising in wounded men who may have had no lice on them for some weeks, as the dried excreta, if blown on to a raw surface, would readily give rise to the disease.

Some further experiments carried out at Hampstead on the migration of lice are also of great interest, as it has been shown that if two men be available, one with a normal temperature and the other with fever, the lice will leave the fever case and pass quickly to the man with the normal temperature. Experiments are now in progress with the excreta of normal lice, as it is possible that the disease is not necessarily carried from man to man by lice but simply from louse to man.

Action Proposed.

In view of these results and their corroboration by the Medical Investigation Committee in France, it is hoped that a very determined campaign will be instituted against the louse, and thus eliminate, or at least reduce, the incidence of a fever which has up to now caused so great a drain on our man power at the front.

The fact that these experiments have been carried out in London is of the first importance, as there can be no suspicion of an accidental or natural infection, for the men employed had not been out of England for many years and had been under observation for some months previous to the experiments; also they were housed entirely apart from the hospital in which the cases of trench fever were being cared for.

The funds for this research have been provided by the Lister Institute of Preventive Medicine.

CASUALTIES IN THE MEDICAL SERVICES.

ROYAL NAVY.

Died on Service.

SURGEON T. S. BRADBURN, R.N.

Surgeon Thomas Stratford Bradburn, R.N., died at Wasperton, Warwick, on March 8th, age 37. He was the only son of the late Thomas Bradburn of Sade Hill, Wolverhampton, and was educated at the universities of Oxford, where he graduated M.A. in 1903, of Edinburgh and Birmingham. He took the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1909, and D.P.H. Bristol in 1913. After acting as house-surgeon and house-physician of Queen's Hospital, Birmingham, and as house-physician of the Brompton Consumption Hospital, he took a temporary commission as surgeon in the Royal Navy in 1914.

ARMY.

Died on Service.

LIEUT.-COLONEL M. E. REPORTER.

Lieut.-Colonel Maneckjee Eduljee Reporter, Madras Medical Service (retired), died of heart failure at Kistna, Madras Presidency, where he was district medical and sanitary officer, on January 18th, aged 67. He was educated at the Grant Medical College, Bombay, where he took the diploma of L.M.S. in 1876, subsequently taking the L.R.C.S. Ed. and L.R.C.P. Lond. in 1877. Entering the I.M.S. as surgeon on October 1st, 1877, he became surgeon on January 1st, 1889, and surgeon-lieutenant colonel on October 1st, 1897, retiring on November 27th, 1902, and rejoined for duty during the war. He served in the third Burma war in 1887-88, taking part in the operations of the 5th and 6th Brigades, and received the medal with two clasps.

Wounded.

Captain J. F. Carroll, R.A.M.C. (temporary).

Captain D. A. Wilson, R.A.M.C. (temporary).

DEATHS OF SONS OF MEDICAL MEN.

Corbett, Reginald David de la Cour, Major Indian Infantry, attached Royal Flying Corps, eldest son of the late Colonel R. de la Cour Corbett, R.A.M.C., died as a prisoner of war at Changri, in Asia Minor, on December 25th, 1914, aged 32. He was born on August 22nd, 1881, educated at Bedford, and at Sandhurst, where he was in the Rugby Fife n, and got his first commission in the Royal Irish Rifles on May 8th, 1901. He served with them in the South African war in 1901-2, and received the Queen's medal with four clasps. On May 2nd, 1904, he joined the Indian Army, being posted to the 48th Pioneers. He became captain on May 8th, 1910, and had reached the rank of major during the war. In 1903 he was on famine duty, and in 1912 was appointed tutor to the Raja of Awa. In 1914 he rejoined his regiment, and went with it to Mesopotamia, and in May, 1916, he was mentioned in dispatches. He was one of the garrison of Kut.

Gough, John Noel, Second Lieutenant Royal Field Artillery, third son of Dr. H. E. Gough, of Northwich, killed in action on

March 8th, aged 20. He was educated at Elstree, at King's School, Canterbury, and at Trinity College, Cambridge, where he held a scholarship. He had served in France for a year. His eldest brother was killed in Palestine last December, the second is serving in Mesopotamia.

Inglis-Clark, Charles, Captain Army Service Corps, son of Dr. Inglis-Clark, of Edinburgh, died of wounds on March 6th. He got his first commission on January 20th, 1915.

Lynden-Bell, Colin Sutherland, Lieutenant 99th Dekkan Infantry, son of Colonel E. H. Lynden-Bell, A.M.S., accidentally killed recently in Mesopotamia. He was educated at Harrow and Sandhurst, joined the Royal Fusiliers, served with them in France in 1914, and was invalided home for wounds. On recovery he joined the Indian army, and had served on the North-West frontier before going to Mesopotamia. His commission was dated August 15th, 1914.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

Major-General (temporary Lieut.-General) T. H. J. C. Goodwin, C.M.G., D.S.O., Director-General Army Medical Service, has been appointed a Companion (Military) of the Most Honourable Order of the Bath for valuable services rendered in connexion with the war.

MENTIONED IN DISPATCHES.

Lieut.-General Sir Stanley Maude, K.C.B., Commanding-in-Chief, Mesopotamia Expeditionary Force, in a dispatch dated November 2nd, 1917, mentioned the following medical officers for distinguished and gallant services and devotion to duty:

Staff and Head Quarters.—Colonel (temporary Surgeon-General) A. P. Blenkinsop, C.B., A.M.S.; Major (temporary Lieut.-Colonel) W. H. Hamilton, D.S.O., and Lieutenant J. B. de W. Molony, I.M.S.

Royal Army Medical Corps.—Brevet Colonels M. H. G. Fell, C.M.G., J. M. Sloan, C.M.G., D.S.O.; Lieut.-Colonel (temporary Colonel) S. F. St. D. Green; Lieut.-Colonels J. H. R. Bond, D.S.O., W. A. Woodside, D.S.O.; Brevet Lieut.-Colonel D. S. Skelton, D.S.O.; Majors (acting Lieut.-Colonels) G. E. Cathcart, J. F. Whelan; temporary Major (temporary Lieut.-Colonel) R. Davies-Colley; Captain and Brevet Major W. McNaughton; Captains W. H. Biggs (T.F.), T. K. Boney (S.R.), A. E. Bonham (T.F.), J. W. Dalglish (S.R.), W. Dunlop (S.R.), M. Foster (S.R.), D. R. Hennessy (S.R.), T. P. Inglis (S.R.), C. M. Ingoldby, J. de M. Kneebone (S.R.), J. W. MacLean, J. P. Mitchell (S.R.), W. K. Morrison, D.S.O., G. N. Smyth (S.R.); temporary Captains R. C. Begg, T. P. Buist, T. S. Keith, G. S. Marshall, V. E. Negus, C. J. B. Pasley, A. Poole, K. N. Purkis, R. Y. Stones, G. S. Terry; Lieutenant (temporary Captain) H. P. Rudolf; Lieutenant J. Ewing; temporary Lieutenants D. F. Borrie, G. Dougan, A. C. Lambert; temporary Quartermasters and honorary Lieutenants C. Hunt, C. E. Malyon.

Indian Medical Service.—Lieut.-Colonels F. W. Gee, F. O. N. Mell, C.I.E., T. B. Kelly; Brevet Lieut.-Colonel C. M. Goodbody, D.S.O.; Majors (acting Lieut.-Colonels) E. W. Browne, C. A. Gourlay, J. C. H. Leicester, W. Lethbridge; Majors (temporary Lieut.-Colonels) R. M. Barron, F. P. Connor; Majors R. J. Bradley, R. Kelsall, D.S.O., W. H. Leonard, T. G. F. Paterson, D.S.O., E. A. Roberts; Captains C. H. P. Allen, M. Das, P. K. Gilroy, G. G. James, D. D. Kamat, R. F. D. MacGregor, M. C. A. A. C. McNeill, W. A. Mearns, J. A. S. Phillips, A. L. Sheppard, J. MacG. Skinner, W. D. H. Stevenson, W. E. R. Williams; Lieutenant W. P. Hogg.

ORDER OF THE BRITISH EMPIRE.

The following medical names appear in the list of further appointments to the Most Excellent Order of the British Empire for services in or for the Overseas Dominions, Colonies and Protectorates and in connexion with the war in France, Egypt and Salonica.

To be K.B.E.—Dr. James William Barrett, C.M.G., for services in connexion with the Australian Branch of the British Red Cross Society in Egypt, etc.

To be O.B.E.—Dr. Edith Helen Barrett, honorary secretary Australian Branch of the British Red Cross Society; Dr. A. Ruskin Cook, medical officer, Church Missionary Society Hospital, Kampala, Uganda; Lieut.-Colonel C. E. P. Fowler, R.A.M.C.; Dr. R. E. Weigall, organizer of motor service for the reception of returned and wounded soldiers.

A special Supplement to the *London Gazette*, issued on March 19th, contains the statements of the acts of "conspicuous gallantry and devotion to duty" for which the decorations announced in the *London Gazette* of October 27th, 1917, and noted in the *BRITISH MEDICAL JOURNAL* of November 3rd, 1917, p. 609, were conferred. The following officers of the R.A.M.C. are included in the list:

Distinguished Service Order.

Temporary Captain John Caruthers Sale, M.C.

He collected the wounded over a large tract of country exposed to heavy fire, and continuously went out by night in advance of the front line searching for the wounded, many of whom he brought back over a difficult ground and under heavy fire. His coolness and determination were a splendid example to his stretcher-bearers.

Bar to the Military Cross.

Temporary Captain Hugh Ross MacIntyre, M.C.

When in charge of the evacuation of the wounded he from time to time led his stretcher-bearers and cleared the wounded, although exposed to fire from snipers. He worked untiringly and incessantly for three days without sleep, and it was due very greatly to his efforts that the regimental aid posts were kept clear of wounded, and cases quickly evacuated to the advanced dressing station. He is fearless in the face of danger, and by his splendid courage and example he inspired confidence in his men.

Military Cross.

Temporary Captain Leslie Haden Guest.

On the night of an attack he gallantly led his stretcher squads under heavy shell fire and collected wounded who were lying out on newly captured ground. By his courageous example and disregard of danger he was the means of saving many wounded men.

Temporary Captain William Llewellyn Aplin Harrison.

He established his aid post within 200 yards of the front line as soon as the objective had been reached, and thereby saved many lives. Though his aid post was twice destroyed by shell fire, he continued at work with complete disregard of danger, inspiring all who came in contact with him by his splendid example.

Temporary Captain William George Johnston.

Whilst in command of the stretcher-bearers evacuating the wounded, he worked under shell fire for fifty-five hours, leading his bearers time after time to collect wounded lying out in the open. On another occasion he went out under heavy shell fire and succeeded in getting out alive some men who had been buried in the forward trenches. His fearless conduct, disregard of personal danger, and devotion to duty saved many valuable lives.

Temporary Captain Robert Kennon.

During the recent operations this officer continued for three days to dress wounded, during which period he was continually under heavy shell fire, and his dressing station was blown in. With the greatest coolness and devotion to duty he continued his life-saving work, and was a splendid example to all ranks.

Temporary Captain John Kirtan.

He went forward under shell fire to dress and collect wounded and help and encourage the stretcher-bearers at their duties, working for five consecutive days without rest. It was largely owing to his excellent work that the evacuation of the wounded of the division was successfully carried out, and by his efforts many wounded men were got into safety.

Temporary Captain Wilfred John Pearson.

When in charge of the evacuation of the wounded he worked under heavy shell fire for fifty hours without rest, and it was largely due to his untiring efforts that the wounded in this sector were got away so quickly. On one occasion, though caught in the barrage of the enemy's heavy guns, and though severely shaken, he continued to work without intermission, his untiring labours being instrumental in saving many valuable lives.

Temporary Lieutenant Henry Marston Layard Crawford.

He dressed and collected the wounded under heavy shell fire, and on the withdrawal he remained with the rearward, still under heavy fire, collecting more wounded. By his pluck and determination he succeeded in bringing in all his wounded, though compelled to make a wide detour through exceptionally heavy and difficult country.

Temporary Quartermaster and honorary Lieutenant Charles Elliot.

Whilst in charge of the arrangements for the evacuation of the wounded, he time after time took men out under heavy shell fire and repaired the line. He frequently volunteered to go forward and find out the position of wounded men lying out in the open. He worked incessantly for fifty hours without rest under fire, and showed a splendid example to others.

The Military Cross has also been conferred upon Captain John Joseph Harper Nelson, I.M.S., for conspicuous gallantry in action.

He tended the wounded in the open for a long period, although exposed to heavy fire of all descriptions. He showed fearlessness throughout, and his example was of great value to all.

Scotland.

THE SYMPATHETIC AND PARASYMPATHETIC SYSTEMS.

Dr. J. J. GRAHAM BROWN, Physician to the Royal Infirmary, Edinburgh, delivered the course of Morison Lectures for this year before the Royal College of Physicians of Edinburgh on March 4th, 6th, and 8th. The lectures were concerned with a review of certain disorders of the sympathetic and parasympathetic systems.

Introduction.

The lectures treated first of the general arrangement, functions, antagonism, and synergic action of the autonomic nervous system. That system consisted of two sets of neurones, the sympathetic and the parasympathetic, governing the organic functions outside the control of the will, smooth muscle, heart innervation, the secretion of glands, and the endocrine organs. The sympathetic and parasympathetic differed in origin and in function. They were antagonistic, yet in such a way as to harmonize for the good of the individual, synergic action taking place in connexion with the sexual activities. Their antagonism was well illustrated in their action on the

pupil, on peristalsis, and metabolism, their reaction to drugs, hormones, and toxins. Normally equipoise was maintained. But one or the other might be temporarily dominant, and that to a considerable extent, within the limits of health. But there were individuals whose sympathetic neurones were in too high a tonus, others in whom the parasympathetic was hypersensitive. Such persons might show no symptoms, but would be readily affected by toxins which had an affinity for the over-sensitized system. They often presented a clinical syndrome by which it was possible to recognize the dominant system, corresponding, as it were, to the old "temperaments," "constitutions," and "diatheses."

The Sympathetic System.

The sympathetic fibres originated in small cells in the medio-lateral tract of the cord and the pre-ganglionic fibres left the cord as the white rami communicantes from the level of the first thoracic to about the second lumbar segment. They had one synapse in a ganglion on their course, then the post-ganglionic non-medullated fibre passed to the effector organ; the synapse occurred either in the segmentally related ganglion of the lateral sympathetic chain, a ganglion at a higher or lower level, or in one of the prevertebral ganglia of the abdomen. An exception was afforded by those fibres which pass direct without a synapse to the suprarenal medulla, which developmentally is part of the sympathetic system; it only secreted adrenalin if stimulated by the sympathetic, and the latter only acted if its myoneural junction was sensitized by adrenalin. The functions of the sympathetic were widespread, and the corresponding clinical symptoms of overstimulation varied. It accelerated the heart and constricted the blood vessels, the splanchnics being most affected. In the alimentary canal it inhibited peristalsis and caused contraction of the sphincters; it inhibited the bronchial muscles, caused anabolic secretion of many glands, stimulated the liver cells, inhibited the external secretion of the pancreas, and thus caused polycythaemia, lowered the threshold for sugar, and regulated carbohydrate metabolism. It also stimulated the thyroid and possibly the posterior lobe of the pituitary, and increased the metabolism of fats and proteins. There was a tendency to an increase of the mononuclear lymphocytes of the blood. Other clinical results were dilatation of the pupil, protrusion of the eyeball, widening of the palpebral fissure, goose-skin, perspiration, pyrexia, accelerated breathing, and greatly increased blood pressure. Varying combinations of these were illustrated by cases, one showing marked unilateral symptoms.

The adequate stimulus for the sympathetic was strong emotion such as pain or fear; it acted as a rapid protective mechanism to brace the organism against danger. The sympathetic was also an instrument by which the ego manifested itself—for example, the eyes altered and lighted up on the recognition of a friend; in this connexion it was remembered that though the fibres appeared to arise in cells of the cord impulses passed down to these from higher centres, possibly from the optic thalamus, which probably influenced also the affective tone of the facial muscles. In some individuals the effects of a strong stimulus might remain, adrenalin and thyroid over-secretion continue, and a condition of what had been called "crystallized fear" result, as in Graves's disease, which was really a disease of the sympathetic system. The thyroid also stimulated the sympathetic apparatus through the suprarenal but was not so essential as adrenalin. Such a condition was more common in the female sex, and the clinical picture was a person of mid-height, spare, thin, of fine build, the features delicate and mobile, and complexion fair; the emotions were not under good control, muscular movements were quick and reflexes sharp, tachycardia was readily produced, the blood showed some mononucleosis, and the sugar threshold was lowered. Drugs which stimulated the sympathetics were iodine, beta-tetra-hydro-methylamine, morphine, and the autocooids adrenalin, thyroid, and probably the posterior lobe of the pituitary. Of the toxins which stimulated it, the more important appeared to be the monamines formed by putrefactive anaerobic action in intestinal stasis (what Barger called "sympathio-mimetic" amines). Of these, tyramine was the most important, and probably many

cases of sympathetic hypertonus were due to the long-continued production of such bodies; hence the good effects often got from the use of intestinal antiseptics.

Sympathetic hypotonus occurred normally during sleep, from exhaustion due to long-continued over-stimulation, and where toxic destructive processes had affected the suprarenal or thyroid, as in Addison's disease and myxoedema. The suprarenal secretion was also depressed by the toxin of tubercle even when the organ itself was not attacked.

The lecturer then spoke of the afferent neurones of the sympathetic system, especially in connexion with the reflex tonus of abdominal muscles, the phenomena of referred pain, and the axon reflex.

(To be continued.)

England and Wales.

THE MARY BIRRELL DAVIES MEMORIAL FUND.

It is little over a year since Dr. Mary Birrell Davies passed away, leaving behind the memory of a life well spent in doing good, not only in matters medical, but also in ameliorating the conditions of life and encouraging to self help and reliance the poorer classes of the city of Liverpool. Many of her friends and patients at once determined to keep her memory green by raising a fund which would be a tangible sign of the esteem and affection in which she was held. The sum received, amounting to £2,400, has been handed over to the University of Liverpool with the object of making one open entrance scholarship for women medical students. The scholarship is of the value of £60 a year, and is tenable for four years. It will be awarded every alternate year.

FINANCE OF HOUSING SCHEMES.

The Local Government Board (England and Wales) has issued a circular to local authorities stating the conditions under which financial assistance from public funds will be given to those local authorities prepared to carry through without delay at the conclusion of the war a programme of housing for the working classes. The arrangement with the Treasury is that the local authority should meet the full cost out of a loan (for not less than seven years), the state undertaking to make a grant relieving the authority of 75 per cent. of the estimated annual deficit. At the end of the period the property is to be valued and 75 per cent. of the excess, if any, of the amount of loan outstanding over the then value of the property is to be met by the state. In rural districts the proportion of the expense to be met by the state may be higher, if the cost exceeds the produce of a rate of a penny in the £. The Royal Institute of British Architects is conducting a competition for suitable designs for houses, and a committee appointed by the Board is considering questions of building construction. A committee appointed by the Minister of Reconstruction is investigating the question of material.

SMALL-POX IN LONDON.

Twenty-seven cases of small-pox have been notified in London, including three in the extra-county borough of East Ham. Mr. F. R. Anderton, Chairman of the Public Health Committee, informed the London County Council on March 19th that there was reason to hope that the measures adopted had obviated the possibility of a serious outbreak. As a matter of emergency, however, the Council decided to make chicken-pox a notifiable disease until June 30th. The Bethnal Green Borough Council had already made such an order for one month from March 6th. The Local Government Board has issued a notice recommending that persons living in or near localities where cases of the disease have occurred, and who have not been successfully vaccinated since childhood, or whose original marks of vaccination are imperfect, should secure the protection afforded by vaccination. It has been ascertained that a person suffering from small-pox in its earliest stage spent several hours in an air-raid shelter, and all the contacts have not been found.

Ireland.

SALARIES OF POOR LAW MEDICAL OFFICERS.

IN connexion with the agitation and the resignations, in certain districts, of Poor Law medical officers for increased salaries, the *Irish Independent* in an editorial says:

In the course of the lengthy correspondence about the grievances of Irish dispensary doctors the fact was demonstrated that there are boards of guardians which cannot, or will not, understand the position of the medical officers in their service. Having settled down into a rut of habit and, perhaps, prejudice, it is hard to get these boards to lift themselves out of it. They seem to think that the doctors are all too importunate in asking for increases of salary, but the same boards may be quite benevolently disposed towards claims of workhouse officials which are urged with much less reason and restraint than those of the medical officers. However, it is evident that the recent correspondence was not without producing a good effect. This is seen in the favourable reception given in various districts to a number of applications for increases which have recently been made by dispensary doctors. If the cases were dealt with solely on the merits there could be no cause of complaint.

IRISH MEDICAL SCHOOLS DINNER.

The Irish Medical Schools' and Graduates' Association held its St. Patrick's Day dinner at Pagan's Restaurant, Great Portland Street, London. Dr. Kenneth Frazer presided. The toast of "Our defenders" was proposed by Dr. Douglas, who mentioned that the guests included Surgeon-General Sir William Donovan, who had had charge of something like a million soldiers in the war. Deputy Surgeon-General Miller, R.N., responded for the navy, and Major Jocelyn Swan for the army. The latter said that two past presidents of the association—Sir Alfred Keogh and Sir Havelock Charles—had taken leading parts in the organization of the medical services in this war. No fewer than forty-two Irish medical graduates had distinguished themselves by signal heroism at the front during 1917. Dr. A. Giles gave "Our visitors," to which Major Willsoughby replied. The other toast, "The Association," was responded to by the president.

Correspondence.

LONGEVITY.

SIR,—Dr. William Bramwell gives a generous approval to my paper, "On the influence of muscular exercises on longevity," but finds that I have not sufficiently insisted on the importance of mental exercise. I therefore hasten to state that I thoroughly agree with him about "the life-long tendency of mental activity," to which I have devoted a paragraph in the little book on *Prolongation of Life*. My remarks in the *JOURNAL* of February 23rd I purposely restricted to muscular exercises, and alluded only slightly to the influence of mental work, and of the tenor of mind, of cheerfulness, and contentedness as prolonging, of gloominess and pessimism as shortening, agencies. Nor have I entered into moral matters, such as, on the one side, the suppression of anger, envy, jealousy, avarice, undue ambition, etc., and, on the other, the cultivation of sympathy, benevolence, helpfulness, and a good conscience, which is a great asset towards a happy old age.—I am, etc.,

Bournemouth, March 18th.

HERMAN WEBER.

SIR,—There is much more to be said on longevity than is contained in the contributions by Sir Herman Weber and Dr. William Bramwell.

To live long without being well in body, mind and soul is wearisome. The difficulty about the whole matter is that most men and women wake up too late in life to know the full importance of the growth of the whole man. We have waited many centuries to obtain Mr. Fisher's Education Bill, which for the first time takes into consideration, and means to put into practice, the education or drawing out of the three essential parts of our nature—namely, the physical, intellectual, and moral. It is when all these qualities are early trained and progressively taught and practised throughout the entire life, that the pleasures of health, mental equipment, and balanced character will be enjoyed even to old age.

Our profession has been slow to preach and practise these great truths, perhaps because of our want of political

and municipal power. I can conceive no greater advantage to our nation at this time than for the whole medical profession, with its unique knowledge, to throw its full weight and power into the present educational campaign.—I am, etc.,

Folkestone, March 18th.

W. J. TYSON, M.D., F.R.C.P.

ATTENDANCE ON DISCHARGED DISABLED MEN AND THE WIVES OF SERVING MEN AND WIDOWS.

SIR,—I am desired by the Minister of Pensions to ask your permission to call attention to a matter of some importance affecting the interests both of medical practitioners and of the public. Cases have come before Mr. Hedge in which both discharged disabled men and wives of serving soldiers or widows whose husbands have been killed in the war have obtained medical attention during illness and on being presented with the bill by the practitioner have appealed to the local War Pensions Committee or to the Ministry for assistance towards meeting it. It is clearly contrary to all principles of sound administration that bills thus presented after the event should be recognized as a charge upon public funds. A disabled man is entitled under the Instructions of the Ministry to apply to his local War Pensions Committee for the treatment necessary to his case, and is instructed to do so by notification at the time of his discharge and by public notice in post offices and elsewhere. Similarly widows of men who have been killed and the wives and dependants of serving soldiers are in cases of serious illness entitled to ask the assistance of their local War Pensions Committee. Practitioners should therefore realize, if they take up cases without previous understanding as to the extent of assistance which will be given by the local War Pensions Committee or the Ministry, that they do so at their own risk and that the Minister cannot be held liable for any charges which may be incurred.—I am, etc.,

MATTHEW NATHAN,

Ministry of Pensions, Secretary's Office,
Westminster House, Millbank, London, S.W.1.
March 19th.

SUPPLY OF ARSENOBENZOL DRUGS TO GENERAL PRACTITIONERS.

SIR,—In reply to Dr. J. A. Butler, I may point out that I did not say that the intramuscular route was clinically preferable to the intravenous: I agree that it is not. I said that the latter constituted the only passport possessed by the doctor usually consulted by the infected "amateur" for the possession of free salvarsan. My point was social, not clinical.

My personal experience with the intramuscular route does not quite agree with that of Dr. Butler, though, like him, I think it unwise to generalize from it. I have given arsenobenzol in some form intramuscularly in about fifty instances, excluding hospital cases, and I have only once seen anything like the disabling pain he describes. I think it is important to use a cream that has not been repeatedly heated, and which contains an adequate proportion of creocamp, but it is also essential to inject deeply in the gluteal muscle, and to avoid proximity to the sciatic nerve.

The bulk of our experience, however, has been obtained in the various hospitals, and I can find there no record of severe pain. I do not agree that in estimating the value of a remedy a large class should be ruled out because they are "under discipline."—I am, etc.,

Sheringham, March 18th.

A. KNYVET GORDON.

STAFF PAY FOR REGISTRARS OF MILITARY GENERAL HOSPITALS.

SIR,—I have for many years urged that medical officers filling the important part of "secretary and registrar" of military general hospitals should receive staff pay in addition to their ordinary military pay. For a general hospital of 500 beds I would give the registrar 5s. per diem extra salary, and for a 1,000 bed hospital 10s. per diem. It is a very important duty, and the pay would be a stimulus for medical officers to study specially this line of staff duty. It seems to me strange so vital a matter has been for years neglected.—I am, etc.,

GEORGE J. H. EVATT, M.D.,

Junior United Service Club,
London, S.W., March 15th.

Surgeon-General (retired)

Universities and Colleges.

UNIVERSITY EDUCATION IN WALES.

THE Royal Commission on University Education in Wales has made a unanimous final report. It recommends the continuance of a single national University of Wales, but a remodelling of the existing organization. The university should set the standard of admission for students and the period of residence and study for the initial degrees, but the approval of syllabuses of courses should be a matter entirely between the teacher and his college. The college should be responsible for the intermediate examinations. The Welsh National Medical School should be organized as an independent constituent college of the university, governed by a council and senate of its own.

A committee, of which Sir William Osler is chairman, met in Cardiff last week to prepare a scheme for the Mansel-Talbot Chair of Preventive Medicine endowed by Miss Talbot. When the scheme had been approved the election of a professor will be proceeded with.

UNIVERSITY OF EDINBURGH.

At a meeting of the General Council on March 13th two proposals affecting medical education were confirmed. The first provides for the introduction into the medical curriculum of instruction in tuberculosis, consisting of lectures and practical work, attendance on which will be obligatory for the degrees of M.B., Ch.B. as from October, 1918. The other proposes that when the chair of *materia medica* falls vacant a separate chair of therapeutics bearing the name of the late Dr. Robert Christison shall be established, and a separate course of therapeutics required. Another draft ordinance approved affected regulations for the admission to Scottish universities; it provides that the educational test for admission should be co-ordinated with the national system of leaving certificates from secondary schools on conditions which will fully safeguard the freedom of the universities. All questions as to entrance will be determined by a Scottish Universities Entrance Board.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

An ordinary Council was held on March 14th.

The Council adopted the following resolution:

That in view of the large reduction in the number of candidates presenting themselves for the first and second professional examinations for the licence in dental surgery, the number of examinations will be reduced to two in the year, namely, May and November.

Diplomas were issued to nine candidates found qualified for the licence in dental surgery at the recent examination.

Election of Council.

There are six candidates for election to the Council of the College on Thursday, July 4th, and four vacancies. Sir Watson Cheyne and Mr. Bilton Pollard will not seek re-election. Sir John Bland-Sutton and Mr. Walter Spencer are again candidates. An analysis of the Council as it now stands appeared in the JOURNAL last week, p. 330. The four new candidates are Mr. J. Lynn Thomas, C.B., C.M.G., of Cardiff, Fellow since 1892; Mr. H. B. Grimsdale, ophthalmic surgeon, St. George's Hospital, Fellow 1894; Mr. F. J. Steward, Guy's Hospital, 1898; and Mr. E. W. Hey Groves of Bristol, Fellow 1905 (Member 1395).

Obituary.

DR. SYBIL LONIE LEWIS, who died at Hull on March 10th after a short illness, was born in 1874. She studied medicine in Edinburgh and Dublin, having previously been trained in nursing and midwifery, and obtained the L.R.C.P., L.R.C.S., and L.R.F.P.S. diplomas in 1905. After serving as assistant resident medical officer at the Larbert Asylum she began practice in Hull, and held the appointment of school medical officer and the honorary medical officerships of the Diocesan Maternity Home, the Hull Sheltering Home for Girls, and the West Hull Crèche. In the spring of 1915 Dr. Lewis volunteered for work in Serbia, and went out there in June under the Scottish Women's Hospitals. She was in Serbia when the country was overrun by the enemy and the hospital staffs taken prisoners in 1915. Although a Red Cross party, they were detained in Hungary for four months, under the roughest conditions, and were not released and sent home until February, 1916. Dr. Lewis went out again in August, 1916, and worked with the Serbian army in Macedonia and among the civilian refugees till December, 1917, when she was recalled by urgent need at home. She received the Serbian decoration of the Order of St. Sava, Fourth Class, in recognition of her devoted work

among the Serbs. Her illness lasted only three days, but, in the opinion of the surgeon attending her, the conditions causing it were contracted abroad, and her name must be added to the growing list of medical women who have given their lives for Serbia.

Medical News.

THE Gill Memorial of the Royal Geographical Society has been awarded to Dr. Cuthbert Christy for his surveys and explorations in Central Africa.

THE Royal Dental Hospital, Leicester Square, has received Canada 3½ per cent. Registered Stock to the value of £500 from the executors of the late Mrs. Gore-Lloyd.

A MILK dealer of Islington was sentenced at the North London Police Court on March 15th to a month's imprisonment with hard labour, and ordered to pay £5 costs, for selling milk adulterated with added water to the extent of 36 per cent.

THE library and offices of the Royal Society of Medicine will be closed from Thursday, March 28th, to Saturday, April 6th, both days inclusive; but officers of the R.A.M.C. and Colonial and allied services will be admitted to the library between the hours of 11 and 6.

A DISCUSSION on industrial alcoholism will be opened by Dr. W. C. Sullivan, medical superintendent of the State Criminal Lunatic Asylum, Rampton, Notts, at a meeting of the Society for the Study of Inebriety, at 11, Chandos Street, W.1., at 4 p.m., on Tuesday, April 9th.

THE graduates of the universities of Durham, Manchester, Liverpool, Leeds, Sheffield, Birmingham, and Bristol form a single parliamentary constituency. Mr. Herbert G. Williams, 130, Ashley Gardens, London, S.W.1. honorary secretary of a Conservative and Unionist Association for the constituency (of which Sir Maurice Abbot Anderson is chairman), desires to obtain the addresses of all graduates in sympathy with the aims of the association.

At a meeting of the Executive Committee of the General Medical Council on February 25th the President was authorized, in consequence of representations from the Food Controller and the Home Office Committee on drug supply regarding the necessity of the discontinuance of the use of certain fats and oils for the official preparations of the *British Pharmacopoeia*, 1917, to announce the alterations and amendments in the *British Pharmacopoeia* rendered necessary by the present emergency.

MR. J. Y. W. MACALISTER was entertained at dinner recently by members of the Library Association, of which he is president. Sir William Osler, who was in the chair, paid a warm tribute to Mr. Macalister's services to the medical profession as what would be called, he said, in America a "merger"—that is, a man who got people together and to work together. He recalled in particular his work in bringing the Royal Society of Medicine into being, by the merging of the many medical societies which used to meet in the house of the Royal Medical and Chirurgical Society.

AT a meeting of supporters of the New Hospital for Women, Euston Road, London, on March 14th, which was attended by H.R.H. Princess Louise, Duchess of Argyll, it was decided to rename the institution the Elizabeth Garrett Anderson Hospital for Women, in memory of its founder. Lady Hall, treasurer of the memorial fund, said that nearly a quarter of the sum of £50,000 for the endowment of fifty beds had already been raised. The Right Hon. H. A. L. Fisher, President of the Board of Education, expressed his deep interest in the medical education of women, especially in relation to the school medical service. The other speakers were the Right Hon. F. D. Acland, Dr. Mary Scharlieb, Dr. Jane Walker, and Dr. Flora Murray.

THE Local Government Board is attempting to obtain a complete register of the blind as a preliminary to drawing up schemes for making suitable provision for the different categories of blind persons. The definition of blindness adopted by the Board is "too blind to perform work for which eyesight is essential." The Board is asking all institutions, societies and agencies for the blind, Poor Law guardians, local education authorities and county nursing associations to give assistance, and has issued a circular letter to county councils and local sanitary authorities, asking them to enlist the help of their health visitors, school nurses and other officers, and also of nursing associations not affiliated with county associations and any other suitable charitable organizations.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

Authors desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are:

1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Aitiology*, *Westrand, London*; telephone, 2631, Gerrard.

2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, *Westrand, London*; telephone, 2630, Gerrard.

3. MEDICAL SECRETARY, *Medisecra*, *Westrand, London*; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin. The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

QUERIES AND ANSWERS.

MOSQUITOS: OILING OF PONDS.

N. B. R.—The following extract from the book by Willoughby and Cassidy, reviewed elsewhere, will supply the information required, but we would recommend the purchase of the book (Lewis, 3s. 6d.):

"In the instances where draining and filling in are not possible, oiling may be done. Crude petroleum or other oil that will make a fairly stable surface film will quickly destroy larvae. Half a pint of petroleum will make a film over about 100 square feet of surface. It should be applied by a sprayer. Failing a sprayer, a sack can be soaked in oil, weighted by a stone, and thrown into the centre of the pond. The oil can also be applied by slow dripping from a tin with a tiny aperture. This method is useful for automatic reapplication in slowly moving water, or at the windward edge of a pond. Theoretically, once a week should be enough for re-oiling, but practically oiling is not a success unless it is done about three times weekly."

INCOME TAX.

W. A. is seeking an adjustment of an assessment based on his predecessor's earnings. Must he return his total fees booked?

*A. The basis of "cash takings" is accepted by the Inland Revenue authorities on the ground that in the long run no difference would arise between the duty paid on that basis as compared with that paid on a basis of total bookings less a proper allowance for irrecoverable debts. But where a fresh start is made with the bookings the assumption no longer holds good, as there are no fees for previous years coming into the cash receipts to swell it out to a normal income, and the requirement to which W. A. refers is in accordance with the usual practice in similar cases. It follows, of course, that when W. A. gives up the practice he will not be liable to assessment on fees paid after the cessation of his connexion with the practice.

LETTERS, NOTES, ETC.

THE following appointments of certifying factory surgeons are vacant: Birstal (Yorks, W. Riding), Clwythout (Carnarvon), Wilton (Wilts.).

SPIRIT DUTY (VOLUNTARY HOSPITALS) GRANT.

THE Local Government Boards for England and Wales and for Scotland are now prepared to receive applications from voluntary hospitals for grants in respect of payments of duty involved by the use during the calendar year 1917, in these hospitals, of duty-paid spirit or drugs containing duty-paid spirits for medical and surgical purposes. Forms of application will be sent only to those hospitals to which a grant was paid last year. Any other hospital which desires to make application should communicate immediately with the Secretary to the Local Government Board for England and Wales or the Secretary to the Local Government Board for Scotland as the case may be.

LUNACY LAW AND EARLY MENTAL DISORDERS.

DR. S. E. WHITE writes to correct an error in the article on this subject published on March 9th, p. 291. The memorial there mentioned was presented in July, 1914, to Mr. Herbert Samuel while he held office as president of the Local Government Board; he did not become Home Secretary until 1916. Dr. White considers this distinction important. The memorial, she writes, supported by the signatures of 330 members of Parliament, expressly stated that the homes or hospitals which it advocated for uncertifiable patients should be free from suspicion of detention and should be "kept wholly outside the jurisdiction of the Lunacy Board." The President took favourable note of this special characteristic, and that the proposal could be carried out administratively

by the Local Government Board without changes in the Lunacy Laws, which are only applicable to cases where restraint has become judicially imperative.

ELECTRIFIED SEEDS.

DR. CHARLES MERCIER (Parkstone) writes: I am obliged to you for placing my assertions with respect to the electrification of seeds on the same level as those of Professor Arrhenius with respect to the electrification of growing children. Perhaps you will allow me to point out that the two assertions are not quite comparable. Professor Arrhenius's assertion with respect to the result of electrifying growing children was based on a single experiment. Mine is based on hundreds of experiments. His one experiment was carried out by an ignorant woman who completely misunderstood her instructions. The many experiments to which I refer were made, some by an experienced scientific experimenter, others by practical men whose living depends on their practice in this matter, and who have, as the result of their experiments, adopted the practice. The result of the one experiment was not checked, even by himself, before Professor Arrhenius published it. The results of the experiments on seeds have been checked by experts of the highest authority and of immaculate integrity. No doubt electricity is a word to conjure with, and as I am not unfamiliar with paranoiacs, I am quite aware that effects are sometimes wrongly attributed to it; but I think my contributions to your pages in the last thirty years or so are evidence that I am not excessively credulous, nor apt to accept assertions at their face value, without scrutiny, and without examination of the evidence on which they rest. My advice to those who doubt, as I did, the efficacy of electrifying seeds is contained in the classical, if somewhat discredited admonition, Wait and see.

PART-TIME MEDICAL OFFICERS OF HEALTH.

DR. A. W. LEMARCHAND (Barnstaple) writes to point out the advantages which a part-time medical officer of health might obtain, through his official position, over other general practitioners in the same area. He maintains that a whole-time public health service should be instituted for all districts, the officers being answerable to a central authority, and not to small local councils. This raises a matter of policy which has frequently been discussed in the past. It is one which might properly be brought to the notice of the Representative Meeting through the Division of which our correspondent is a member.

A SUGGESTION FOR EMPIRE DAY.

WE have received a letter, signed by representative medical practitioners and educationalists in Sheffield, expressing national solidarity and determination to see the war through, and advocating the need for a declaration of policy on schemes for social reform. The signatories suggest that the medical and teaching professions are in an exceptionally good position to initiate a response to Mr. Bonar Law, who in the House of Commons lately said he did not believe the spirit of this country was weakening in the war, and that if the question could be put, "Are you prepared to go on with the war until the results you set out to achieve have been attained, or are you not?" the response would be astonishing alike to our enemies and ourselves. The signatories suggest that the two professions should take steps to arrange for public meetings to be held throughout the country on Empire Day, for the purpose of declaring determination to secure a satisfactory peace and to promote schemes for reconstruction after the war. The medical signatories are: Dr. J. B. Leathes, Dean of the Faculty of Medicine; Mr. R. J. Pye-Smith, Emeritus Professor of Surgery; Dr. H. Scurfield, Professor of Public Health; Dr. Sophia Witts, Honorary Secretary of the Sheffield Branch of the British Medical Association; and Dr. A. W. Forrest, Honorary Secretary, Local Medical War Committee.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE following subscriptions to the Fund have been received during the week ending March 18th:

	£	s.	d.		£	s.	d.
Dr. Matilda Hunt ...	3	0	0	Dr. F. R. Mallett ...	1	1	0
Mr. Herbert Tilley ...	5	0	0	Dr. Mark Style ...	2	2	0
Dr. Charles Pollard ...	2	2	0				

Subscriptions to the Fund should be sent to the Treasurer, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank Limited.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

Harveian Lecture

ON

THE FUNCTIONAL ANATOMY OF
THE HEART.*

BY

ARTHUR KEITH, M.D., F.R.S.,

CONSERVATOR OF THE MUSEUM OF THE ROYAL COLLEGE OF
SURGEONS OF ENGLAND.

ABOUT the middle of last century, when physiologists broke away from anatomists, they stole our patron saint—Harvey. Yet Harvey was an anatomist; from 1615, when he was 37 years of age, until 1656, when he was 78, he was the leading lecturer on anatomy in London. It was the application of a right method to the study of the structure of the human body which led him to see that the heart was a double pump forcing the blood to circulate throughout the body.

To understand how Harvey became an anatomist we must follow him to the University of Padua in the last year of the sixteenth century,¹ when he was in his twenty-second year. It was a fortunate circumstance for Harvey that Fabricius, Professor of Anatomy at Padua, was then reinvestigating the occurrence and use of valves in veins. He explained to his students that valves did not occur in arteries because in them the blood ebbed and flowed; but they were absolutely essential for veins in order that the venous blood, which was designed for the nourishment of the tissues, might be evenly distributed to all parts of the body. Were the veins of the arms and legs destitute of valves, it was quite clear, he maintained, that blood would gravitate to the hands and feet and so rob other parts of the body of their just share. We see, then, that Fabricius was studying the anatomy of the various parts of the human body in order to find out the purpose which they served; he was a functional anatomist. We may smile at his conclusions, but we could not make a greater mistake than to condemn his methods, for it was by following Fabricius's example that Harvey was led to his great discovery.

We have no exact information relating to Harvey's investigations between the time of his return to England in 1602 and his appointment as Lumleian lecturer at the College of Physicians in 1615. During those thirteen years he dissected many kinds of animals,² for Harvey was not only a functional anatomist, but a comparative anatomist and embryologist as well. We have only to turn to his introduction to his book on the motion of the heart and blood in animals to discover the manner in which he proceeded to work. He used anatomy as a touchstone on which to test the physiological theories of his day—the theories which Fabricius could expound so convincingly to his students. It was impossible to gainsay the then dominant theory relating to the use of veins. From an anatomical point of view the theory was apparently sound. The products of digestion certainly passed into the radicles of the portal vein and were "concocted" in the liver before being passed into the systemic venous system. The theory explained the existence of the liver and the distribution of veins to the most distant parts of the body. Fabricius had given the reason for the presence of valves in veins—except those in the jugular veins at the root of the neck. Harvey was quick to note that they pointed the wrong way, if Fabricius's theory were true. His real difficulties began when he sought to explain the parts connected with the right side of the heart. The blood entered that side of the heart, so he had been taught, for two reasons: (1) To supply the lungs with nourishment; (2) to send a supply to the left ventricle through the interventricular septum. "Why, then," asked Harvey, "is the vein which carries the blood from the right ventricle to the lungs given the coats of an artery and made as large as the aorta which has to supply 'vital' blood to the whole body?"

To men of Harvey's time the explanation of air passages to the lungs and of venous passages leading from the lungs to the left chambers of the heart were perfectly satisfying.

They were the means by which air reached the left ventricle of the heart. In that chamber the air mixed with the transuded venous blood, and so vital blood was brewed—the blood which gave life and heat to all parts of the body. That the heart was the centre of life and heat had been proved beyond all dispute. Cut out the heart of an animal, and what happens? It died and turned cold; that was plain proof of the truth of the thesis. That air was necessary for the brewing of vital spirits in the left ventricle was a matter of common knowledge. Occlude the windpipe and an animal died, because the element necessary for the manufacture of "vital spirits" no longer reached the left ventricle. The left ventricle and arteries were clearly designed for the distribution of life-giving blood to all parts of the body. The heart could be felt to expand and suck the blood in, and then in turn the arteries could be felt to swell and suck the blood out. The blood ebbed and flowed in the arterial channels. It was a law of nature to ebb and flow. The sea ebbed and flowed; so did the breath.

To this physiological theory Harvey applied the critical judgement of the anatomist. No theory of the function of an organ could be true that did not explain every detail of its structure. To trace the direction of the blood current he took the valves as his guide. The venous valves pointed in every case towards the heart. The valves in the right side of the heart directed him towards the lungs; the valves on the left side of the heart directed him away from the lungs and towards the arteries. There was only one theory which accounts for all of those facts—namely, that the heart acted as a "water-bellows," a double pump, and in order that it could so act he had to presume that the blood moved in a circle. Such a theory of the heart gave a complete and absolutely satisfying explanation of all points in its structure; Harvey could conceive no other theory that would account for all the details of the heart's structure.

Harvey's theory was originally an anatomical hypothesis, but being a man who knew how deceitful hypotheses may prove to be, he put it to the test of experiment. He examined the movements of the living heart; he tested the flow of blood in arteries; he noted the flow of blood in veins. He found the flow to be such as his anatomical reasonings had led him to expect. But to the day of his death his conception of a blood circulation was still a theory; three years after his death in 1657, Malpighi saw with his eye those passages which lead from arteries to veins—passages which Harvey had pictured only in the eye of his imagination.

It might be said that the anatomical methods applied by Harvey at the commencement of the seventeenth century are not applicable to the conditions which prevail at the beginning of the twentieth century. I will give an example to show that they are—that they will be applicable as a basal principle in biological research for all time. Soon after the introduction of Roentgen rays in 1895 I used the method of transillumination to study the action of the crura of the diaphragm. I could not see how it was possible for the crural parts of the diaphragm to contract without acting directly on the heart and roots of the lungs, because the pericardium links the middle part of the diaphragm to both of these structures. I found that it did act directly on them. In the course of my investigations I was led to study the exact attachment of the musculature of the auricles to the pericardium, and thus indirectly to the diaphragm. That led me on to investigate other points in the musculature of the heart. In the course of these investigations I had noted the fine tendon-like structures in the left and also in the right ventricle. I never investigated them; I supposed them to be, as other anatomists had supposed them to be, means for preventing over-dilatation of the ventricles.

In 1906 Tawara, a Japanese, working in the laboratory of Professor Aschoff, discovered that these tendon-like structures were the arborescences of a muscular trunk which commenced in the region of the auricles and descended on each side of the interventricular septum towards the apex of the heart. Tawara explained the presence of the bundle and its branches by supposing that they formed a system for conducting and distributing impulses from the auricles to the ventricles of the heart. Erlanger and others proved by experiment that his guess was right. Tawara noted that the bundle at its

* Delivered before the Harveian Society of London, March 21st, 1918.

commencement in the auricle was made up of a peculiar muscular (nodal) tissue, in which he supposed the inception of the contractile impulse took place. In the following year Major Martin Flack and I, while investigating hearts on which Sir James Mackenzie had made his classical polygraphic records, discovered tissue of a nodal nature at the junction of the right auricle and superior vena cava. We supposed, because of its position and structure, that this node was the centre at which the heart-beat commenced. In 1910 Dr. Thomas Lewis and Dr. Wybau proved by electrical means, and independently of each other, that our guess was right. You can see that Tawara, Flack and I were applying Harvey's anatomical methods; Erlanger, Lewis, and Wybau applied his experimental methods. Harvey realized more fully than any anatomist that structure is a sure guide to function; that no physiological theory can be true unless it gives a complete and final explanation of all points of structure.

Taking Harvey as our guide, then, let us see how far our modern functional conception of the heart falls short of giving a full and satisfactory explanation of its structural features. We shall take the apical region first. Why are the ventricles of the mammalian and avian heart shaped like a cone? Why is it that the wall of the ventricles in the region of the apex is so thin that even in a cart-horse it is only 2 mm. in thickness, while the rest of the ventricular wall ranges from 10 mm. to 25 mm. in thickness? Why do the spiral fibres of the ventricles form the well known apical vortex? Why do the main arborescences of the A.V. bundle terminate in the apical region so that, as Dr. Thomas Lewis has demonstrated, the contraction wave is first manifested there? The arrangement of the musculature of the heart, both of auricles and of ventricles, is so complex that not any one of us has succeeded in giving a satisfactory explanation, yet we cannot claim to have mastered the mechanism of the human heart until we can give a functional explanation of its architecture.

In searching for an answer to some of the questions I have placed before you, we have to remember that the heart is a pump of a peculiar kind. In all forms of pump invented by man only one part of the wall is movable (the piston), and it is moved by a power which lies outside the pump. In the cardiac pump the whole wall is movable and the power is resident in every part of the pump wall. The expelling energy is manufactured in the wall of the pump—not in an adjacent boiler. Further, we must remember that the human heart is made up of a central or principal pump—the left ventricle, to which is attached three subsidiary pumps—the right ventricle for the maintenance of a pulmonary circulation, and the right and left auricles—loading pumps for the right and left ventricles. I brush aside a theory which is prevalent at the present time, a theory that defines the auricles as mere reservoirs. No one who has given attention to the elaborate architecture of the auricular musculature can countenance such a theory.³

As practical engineers we must look into the manner in which the cardiac pump is fixed. Each chamber of the heart must have its fulcrum—the point from which its musculature obtains a fixed point—before it can exert its power. The auricular pumps are fixed to the dorsal wall of the pericardium, and through extensions of that sac, and by means of the pulmonary vessels and the lungs, they are fixed to the walls of the thoracic cavity—both costal and diaphragmatic. When we open the thorax we at once undo the fixation of the auricles. Professor Berry Hayscraft⁴ was, I believe, the first to recognize that fact. There are two points of fixation—two fulcra—from which the musculature of the ventricular pumps act. There is, in the first place, the ascending aortic stem fixed within the cupular part of the pericardium and the extensions of that membrane to the neck and to the roots of the lungs. There is, in the second place, the apex of the heart itself. By a most cunning mechanism—one of the most marvellous in the body—nature has converted the apical region of the heart into a movable fulcrum from which its ventricular musculature can and does act. In lower vertebrates, such as the tortoise, the mechanism of apical fixation is supplied by a ligament which anchors the blunt curvature of the ventricular chamber to the pericardial sac.

We have been discussing the fixation of the complex four-chambered cardiac pump; we must now look into a

more important matter—the manner in which the ventricular chambers of the heart are fixed. For that purpose we must appeal to comparative anatomy and embryology for help. From these sources we learn that the primitive tubular heart undergoes an extraordinary transformation in the human embryo—a transformation not unlike that which takes place in the stomach. In the stomach one border undergoes a rapid and extensive development to form the greater curvature, while the other is retarded in growth and becomes the lesser curvature. In some animals the lesser curvature is so short, so suppressed, that the oesophageal and pyloric orifices are almost in contact. In the ventricular part of the cardiac tube the lesser curvature undergoes so great a degree of retrograde development that the auricular or proximal orifice comes to be situated side by side with the aortic or distal orifice, with only the anterior cusp of the mitral valve between them. The greater curvature has grown out as evaginations to form the ventricular chambers, leaving an untouched part between them to form a septum. The beginning and end of the ventricular tube have come to rest side by side on the lesser curvature, and form what we call the "base" of the ventricles.

It is quite clear that the anterior cusp of the mitral is a most important landmark on the ventricular base; it separates the auricular commencement from the aortic termination of the ventricular tube. The distinction between auricular and aortic bases is one of the utmost practical importance. When the ventricles contract it is the auricular base, surrounding the mitral and tricuspid valves, which becomes greatly reduced in size; the aortic base is, from a functional point of view, scarcely altered. When the ventricles contract the aortic base becomes a fulcrum from which the expelling musculature acts, while the auricular base descends towards the apex,⁵ drawn by a musculature which acts from the apical fulcrum. The auricular and aortic bases are contrasted in both a morphological and a physiological sense. The descent of the auricular base necessarily enlarges the auricles; the movements of the auricular part of the ventricular base provide a key to the venous pulse. They do more than that, they give us a clue to the muscular architecture of the ventricles.

The complex architecture of the ventricular musculature was, in Harvey's time, a well-worn theme. A century and a half after Harvey, Hunter dismissed the matter by saying: "Much more pains than were necessary have been taken to dissect and describe the course and arrangement of the muscular fibres of the heart." The principle, however, which Hunter steadfastly applied to the elucidation of muscular action does prove of the utmost assistance. For Hunter it was a law that no muscle acted alone; every muscle acted in co-operation with an antagonist. His supreme example was the circular muscular coat of an artery. In the bowel the circular fibres have longitudinal fibres as their antagonists, for the effect of contraction in a circular muscular coat is to diminish the calibre of a tube, and at the same time to increase its length. Hunter saw that arteries were elongated by the contraction of their muscular coat, and regained their normal length by the contraction of their elastic coat, the muscular and elastic coats being antagonistic.

When we apply Hunter's principle to the study of the muscular coats of the left ventricle we see that we have to deal with a co-ordinated antagonism between a very massive circular "expelling" coat set between an outer and inner spiral coat. That principle will not help us unless we also recognize the two fulcra or fixed points of the left ventricle—the aortic fulcrum and the apical fulcrum. The fixed axis of the left ventricle passes from the mouth of the aorta to the apex; all the muscular fibres of the left ventricle are so set that in contraction they approach that axis. Besides the principle of antagonism and of fulcra, there is a third principle involved in the architecture of the ventricular musculature. The principle of the iris diaphragm is utilized. All the muscular coats or fasciculi of the heart are so set that they ultimately end in the internal spiral coat of the left ventricle, just as every segment of an iris diaphragm takes a share in forming the margin of its pupil. Without doubt the left ventricle represents one of nature's greatest mechanical triumphs.⁶

When we apply the principles just enunciated to elucidate the muscular architecture of the heart we are at once

impressed by the functional importance of the region of the apex. The chief terminal arborescences of the A.V. bundle end in the trabecular network of the apical region. Dr. Thomas Lewis¹ has demonstrated that the apical region is the first to pass into contraction with the onset of ventricular systole. When we open the ventricles we see that their internal musculature—columnae carneae and musculi papillares—commence in the apical region and divide into two sets. The larger set terminates in the auricular or movable base, the smaller or septal set in the fixed or aortic base. When we examine the outside of the ventricles we find the same arrangement in the spiral fibres. They commence in the vortex of the apex and divide into two sets—an extensive one which ends in the auricular movable base, and a less extensive, which ends in the fixed aortic base. Between these outer and inner sets is placed the great middle driving muscle of the left ventricle; its spirals are so closely pressed together that they give the appearance of being purely circular; we may speak of them as the circular set. The circular musculature, acting by itself, would diminish the circumference and at the same time lengthen the lumen of the ventricle; the elongation is antagonized by the internal and external apico-basal musculature. We know that, at least in the earlier phase of ventricular systole, the auricular base approaches the apex and therefore the circular fibres are more than antagonized; in the later stages of ventricular systole the opposite is the case; the circular fibres become dominant and press again on the auricle, raising the intra-auricular pressure. The apico-aortic fibres are purely sustaining in function; they neither shorten nor lengthen in systole.

In several respects the structure and mechanism of the right ventricle is peculiar. There is incorporated in the infundibulum of the right ventricle a chamber—the pylorus of the primitive cardiac tube—an element which has completely disappeared in the left ventricle. The pulmonary orifice does not serve as a fixed point for the ventricular musculature; the infundibular septal bands of the right ventricle act from the aortic base. Further, the right ventricle has only one wall—the lateral; its septal wall—the interventricular septum—is part of the left ventricle; it takes only a passive share in expelling blood from the right ventricle. On the other hand, the right ventricle is provided with a highly developed internal musculature passing from its apex to the auricular base. The systolic movement of that base is more marked on the right side than on the left side of the heart. Hence we find in the lateral wall of the right auricle a well-developed opponent set of muscles—the musculi pectinati. In auricular systole the musculi pectinati elongate the apico-basal fibres of the right ventricle; in ventricular systole the opposite occurs.

I noted, when investigating those hearts in which Sir James Mackenzie first observed that the auricles had ceased to functionate—from auricular fibrillation, as was afterwards proved—that a condition was present similar to that which occurs in a limb when a set of muscles undergoes contracture from paralysis of the opponent group. In such cases the lateral wall of the right auricle had become elongated and stretched, while in their opponents—the apico-basal fibres of the right ventricle—an extreme degree of shortening had occurred.

I have merely touched on some of the unsolved problems relating to the structure and mechanism of the heart. I am content if I have succeeded in showing that Harvey's methods of investigating anatomical problems are still the best that we anatomists can adopt.

THE TOLERANCE OF PHYSICAL EXERTION, AS SHOWN BY SOLDIERS SUFFERING FROM SO-CALLED "IRRITABLE HEART."

By THOMAS LEWIS, M.D., F.R.S., F.R.C.P., D.Sc.,
PHYSICIAN OF THE STAFF OF THE MEDICAL RESEARCH COMMITTEE;
ASSISTANT PHYSICIAN, UNIVERSITY COLLEGE HOSPITAL.
(From the Military Heart Hospital, Colchester.)

It is now two years since we introduced at the Military Heart Hospital, Hampstead, a system of graded drills, arranged from exercises in the army exercise book, and employed these both remedially and as means of grading soldiers returned to us for the condition known as "disorderly action of the heart," "irritable heart," etc. We have repeatedly contended that the surest means of gauging capacity for physical endurance is to test the men upon drill, the highest grades of which should approach in their severity the tasks which will be set to these men when they return to their dépôts. The test of capacity for work should be the observed reaction to work. That this thesis has been justified fully is shown clearly in an article published recently elsewhere,¹ in which the after-histories of 239 graded out to duty categories by this system are compared with the recommended categories of discharge. This comparison is reviewed in the subjoined table:

Recommendations.	Disposition within 11 Months.
Fit for general service 72	Full duty overseas, 79: Known to reach firing line (of whom 26 make good) 35 Not known if in firing line 23 Known not to have been in firing line 21 In provisional units 30
Likely to be fit for general service within 3 months 47	Full duty home service 8 Light duty overseas 7 Labour companies (H.S.) 23
Light duty; unlikely to be fit for overseas within 3 months 20	Light duty (H.S.) 33 Sedentary duty 16
Light duty, but unlikely ever to be fit for service overseas 68	Under treatment 5 Discharged permanently unfit 38
Sedentary work at home ... 32	
239	239

This system and its results have aroused a good deal of interest, and a large number of military hospitals both at home and abroad have adopted it; others are following suit. Since the recent removal of the heart hospital to Colchester we have continued to receive numerous inquiries as to the details of our method. In part these have been described in previous publications.² In the present article the work of the medical officer's examination room is described, his method of prescribing exercises, and his method of judging the toleration of exercises so prescribed.

The drills now in use are termed B 15, C 15, BC 30, C 30, and D 30,* the letter indicating the stiffness of the exercises, the number the duration of the drill in minutes. B 15 consists of simple movements, and calls for no considerable expenditure of energy; D 30 includes many of the stiffest exercises of the army exercise book, and entails thirty minutes' hard work.

Seeing that most of our patients are recently from France, all those cases to whom drills are prescribed start on the easiest drill, and progress from this to those of higher grades, according to tolerance. A few days or a week upon the two 15-minute drills suffices; a week is usually spent on each of the three 30-minute drills. Men who promise well may be kept a week or so longer on the highest grades of drill to harden them. It is a rule of the hospital that patients upon 15-minute drills are to be considered unfit to leave the hospital premises except under escort; those on 30-minute drills are given afternoon passes freely. This rule has the advantage of stimulating the men to accomplish the 30-minute drills. All men on exercise C 15 and BC 30 go regularly for route marches in the early afternoon; these are short marches of one or two miles in the immediate neighbourhood of the hospital, and at slow time. Men in classes C 30 and D 30 are taken for longer marches of four to five miles in the

* Two of our original drills, A 15 and AB 30, have been discarded.

country at a brisk pace. The exercises and marches are supplemented by outdoor games. At suitable intervals all men are examined as they come from drills or marches. It is understood that any man who feels his drill or march to be beyond his power is to report at once to his medical officer. The drill instructors are ordered to report upon men who seem to them to tolerate exercise badly, and, on the other hand, upon any men who fail to make reasonable effort. Co-operation between the medical officers and the instructors is a very essential feature of our system, and much is left to the instructor's discretion. It is the habit of most medical officers to see each man immediately after he has taken the first drill of each grade; other officers prefer to raise the grade more automatically, and to await complaints from such men as feel themselves hard pressed. At the examination, whether it be at the dictation of the medical officer or drill instructor, or at the wish of the man, questions of a general nature only are asked; the rule is to allow the man to tell his own story; it is inadvisable for the officer to introduce any symptom into the conversation. Notes are kept on simple forms provided for the purpose; each symptom complained of is entered, as are corroborative signs and readings of pulse-rate, etc. This sheet forms in the end a summarized history of the work accomplished and the reaction to it. In the average one or two examinations of each man are made weekly directly after exercise. Medical officers are careful to conceal so far as possible the particular symptoms or signs upon which they judge tolerance.

SIGNS AND SYMPTOMS AFTER DRILL.

The chief complaints of the men as they come from drill are of breathlessness, precordial pain, palpitation, giddiness, and fatigue. It is essential that objective evidence of symptoms should in each case be found before a complaint is allowed to weigh. Most patients emphasize a single symptom, and emphasize it constantly; a changing symptomatology can rarely be corroborated by outward signs, and is to be distrusted. Some men complain on all occasions and in equal degree from the lowest to the highest exercise; others complain little. The medical officer has ever to be on his guard against those who exaggerate their sensations, and equally on his guard against those who are reticent. The tolerance of exercise is to be judged by physical signs, and not by symptoms; symptoms are chiefly of value in directing the attention quickly to physical signs. It has happened more than once that a medical officer has laid recognizable emphasis upon a particular symptom, and that it has led to a corresponding epidemic in his service.

Facial Expression and Breathlessness.

The facial expression when it exhibits genuine distress is generally that associated with breathlessness. The accessory muscles begin to be called into play, the alae

nasi are expanded, the tendons of the sterno-mastoid lift, and the lips part a little; where there is greater distress the alae nasi are active, the eyebrows are drawn together, frowning the forehead vertically and yielding an expression of anxiety or actual pain; the mouth opens wider, its angles droop, and the breathing is more audible. If questions are asked, the breathing is ill-regulated during the replies, the flow of words is interrupted by inspiratory movements. Not infrequently, and especially where there is fatigue, a slight but distinct dusiness develops under or around the eyes; pallor or sallowness of the whole face is not unusual. The facial traits deserve careful observation, for they cannot be simulated; rapid breathing is by itself a scarcely sufficient evidence. In a few patients in whom distress has been frequent and has been experienced for long periods, the altered facial expression is maintained at rest.

Photograph of a patient, aged 28, admitted for long-standing and severe "D.A.H." The photograph was taken immediately after fifteen minutes' easy exercises (B 15), and shows the tension of the sterno-mastoid, slightly opened mouth, and dilated nostrils. The eyebrows are depressed, the forehead furrowed (the central furrow is permanent). The face expresses fatigue and the anxiety of early breathlessness.

Precordial Pain.

This is a common complaint after exercise; it is to be checked by physical examination. With the chest stripped, the hands of the examiner are placed outspread symmetrically on the axillary and sub-mammary regions and pressure is exerted as though to steady the chest or to bring the patient to a more convenient position. This simple action may be sufficient to disclose hypersensitiveness; in some patients, indeed, the slightest pressure on the left precordial region and a wide surrounding area is resented. In others it is necessary to slip the hands higher, bringing the thumbs over the borders of the pectoral muscles and pressing again, or to proceed further and while interrogating the patient, to grasp the pectoral folds with increasing firmness between thumbs or fingers. Where the muscles are sensitive on the left side the patient winces, the left shoulder is depressed, the facial expression alters, or the reply is momentarily interrupted or actually broken off by a movement or expression of protest. When no

hypersensitiveness of the left chest wall is detectable after exercise, the plaint of pain may usually be neglected. In extreme cases hyperaesthesia is found beyond the chest area and exists in the skin of the upper arm; not infrequently it also involves the tendons of the sterno-mastoid muscles. Tenderness of the anterior border of the trapezius muscle suggests a closer examination for signs of early tuberculosis. Patients should not be asked, Is this or that region sensitive?

Palpitation.

A complaint of palpitation is to be neglected as such, but is serviceable as a guide to persistent or excessive tachycardia. The usual rate of the heart's action while a patient is up and about, and especially after set test exercises, is of much importance. It may be normal, raised, or very high. To give actual rates might create a false impression. Heart-rate cannot be used by rule of thumb; rates vary too much with circumstances, and in

general it is impracticable to render these uniform. However, the conditions pertaining to a particular service may be maintained sufficiently constant for different patients and at repeated examinations of the same case. It is essential that heart-rates should be regarded broadly, and particular emphasis is to be laid upon consistency of separate readings. Thus, a patient who reports himself as disturbed by a given drill, will usually show uniform high readings after that drill if distress is genuine; and these high readings will be foreshadowed by raised rates after drills of lower grade. Equally important is consistency between these drill rates, the routine ward rates, and the rate obtained by test exercises.*

Giddiness.

This is a common complaint, but one which is given for the most part in the initial stages of treatment. It consists of transient dizziness or dimness of vision, and is often described as a cloud before the eyes. Rotation of surrounding objects is not experienced. Giddiness may be felt after the patient has stood quietly for some while, immediately at the cessation of effort, or on rising to the upright position abruptly. As a prognostic sign it has little value.

Fainting.

Although nearly 3,000 patients sent to us with diagnoses of "D.A.H." or "V.D.H." have now been submitted to graded drills, there has been no single accident of consequence. Where several hundred men are drilled each day, a fainting attack on drill is less than a monthly incident. The chief form of attack, and one which may always be regarded as genuine, is that accompanied by a feeble and slow heart action (30-50). It may be preceded by a short interval of giddiness, by a sense of weakness or unsteadiness. Consciousness is lost, and the fall is sudden, but rarely heavy. Pallor and sweating are present. Involuntary movements are slight, and usually confined to the face and arms; a general rigidity may be developed; the tongue is not bitten, neither is the urine passed. Nausea or vomiting may be present. The attack lasts from a few seconds to a few minutes, and is followed by lassitude and headache. A history of earlier attacks is common; these are associated usually with emotion (sight of blood, etc.), long standing at attention or the cessation of sudden effort; they do not occur in recumbency. Recovery is always complete, and an attack should not break the routine of drill for more than forty-eight hours. Attacks which are inconsistent with this picture are to be viewed with suspicion unless they may be ascribed to epilepsy.

A complaint of *fatigue* or *exhaustion* is rarely unaccompanied by other complaints, and may be disregarded unless often repeated and accompanied by signs, such as pallor, or by uncontrollable tremor of lips or limbs, or by signs of breathlessness, as the grade of exercise is raised. Stiffness of the limbs or trunk muscles, accompanied by tenderness, is experienced by some unpromising cases to an unusual degree as an after-effect of short exercise. Pain in the axillary region, back, or limbs is usually related to a particular action during drill, and as a general rule does not endure.

Simulation.

If it were wise it would be impossible to hide the meaning of the exercises or their use for sorting purposes from the patients, and they come to understand the significance of any deliberate special examination. We believe that complaints of distress, where absolutely no distress exists, are on the whole rare. Such complaints do not deceive; the manner of their presentation awakens doubt; they are unaccompanied by objective signs or the signs are incompatible with the complaint.

The over-emphasis of symptoms actually experienced is somewhat more difficult to recognize and is undoubtedly common; it is recognized by the same careful comparison of the objective and subjective. Medical officers will be well advised to guard against wilful efforts to produce or to exaggerate signs of distress. A man returning from exercise to the medical officer's room will from time to

time sprint on the flat, dash upstairs, or perform vigorous exercises before opening the door and presenting his wrist for examination. But such attempts are not easy to maintain, and repetition is essential to their success. The man must repeatedly risk detection by a member of the staff, or, maybe, fails to find his opportunity; in the last case his observed reaction is out of harmony with former reactions. The genuineness of a sudden increase in the reaction to exercise is to be tested by visiting the man while he is at drill, or by imposing simple exercise tests in the examination room or ward. The constant supervision of drill by medical officers has been abandoned as both unnecessary and inexpedient; the men work better and more uniformly when left to the drill instructor. No doubt the voluntary production of distress is overlooked from time to time in individual cases, but it cannot long be concealed from the man's comrades, and many of these at once resent the deception. If less gross, the deception may be contagious, and comes to be practised by small groups of men; its early discovery is from that time certain. When discovered, it is met at once by placing the man upon a higher grade of drill without comment.

The other and brighter side of the picture is the man or men who steadily refuse to complain; these tax the medical officer's power of discrimination most of all. Medical officers who get to know their men, who can win their confidence, who treat them tactfully and fairly, experience little difficulty. By far the larger part of our patients desire only full examination and consideration, and recognize the justice of the final decision, understanding for themselves that they are judged for grade of service according to their proved tolerance for work.

NOTES ON RHEUMATOID ARTHRITIS.*

BY

ERNEST A. DENT, M.B., C.M.,

PRESIDENT, GLOUCESTERSHIRE BRANCH, BRITISH MEDICAL ASSOCIATION.

I FIRST had the opportunity of making a special study of rheumatoid arthritis and allied conditions when working at Buxton several years ago. Much has recently been done in investigating its nature, and means for its relief or cure. It is in reference to these sides, and to the differential diagnosis, rather than to the clinical types, that I wish now to allude.

Rheumatoid arthritis has been defined as a progressive degeneration of joints of a special kind, accompanied by atrophy of some structures and hypertrophy of others, but it is really no more than a name given to a number of conditions the exact cause of which is unknown. It is probable that there is more than one disease to account for the different types. The course is variable, but is usually towards irrevocable damage to structures involved. It is a disease of great antiquity, and although it has long received much attention, there is perhaps no other disease in which such confusion exists as to its pathology and place in medicine.

During the last few years bacteriological researches have to a great extent modified former ideas and given light from a new direction. Joints have been aspirated and the fluids so obtained examined microscopically and by cultivation, and it is stated by some observers that a specific organism has been isolated.

Crowe considers that in the majority of cases one particular organism, which he calls the *Staphylococcus deformans*, is concerned; he states that he is able to cultivate it from the urine in about 90 per cent. of all cases of the disease, and that the same organism is recoverable from the urine in many cases of obscure neuritic trouble; he holds that there is a close connexion between neuritis and acute rheumatoid arthritis. Fuller believes that many cases are due to a streptococcus, and that in a very large number of male cases this streptococcus is derived from post-gonorrhoeal infection of the

* The test exercise is employed in all patients on admission as part of the routine examination, and consists of waking briskly up forty steps. The pulse-rate is taken before, immediately after, and two minutes after this test. As an alternative test, we have suggested hopping twenty times on each foot, raising the shoulders approximately nine inches at each hop. In health the pulse will rise to 110 or 120 per minute, but will fall to normal usually within one minute.

* An extract from the Presidential Address on "Some of the affections connected with the war ('shell shock,' 'trench fever,' and 'rheumatoid arthritis')," delivered before the Gloucestershire Branch of the British Medical Association at Cheltenham.

genito-urinary tract; he has operated upon a great many cases of chronic arthritis deformans by opening up and draining the infected seminal vesicles, and although improvement after the operation may be delayed for several months, he says that the ultimate benefit has been, without exception, considerable. Symes considers that it is a disease derived from an intestinal cause, an auto-intoxication of unknown origin.

The general idea seems to be that several micro-organisms have the power of producing the characteristics of the disease; it is extremely probable that in many cases rheumatoid arthritis is an infective disease, and that it is due to micro-organisms settling in the joints or dwelling elsewhere, and elaborating toxins, which cause a progressive inflammatory condition.

Owing to the symmetrical nature of the affection, it was at one time believed to be of nervous origin, and it is likely that some cases are so.

DIAGNOSIS.

The affections for which this disease is most liable to be mistaken are rheumatism, gout, and sciatica. It is in the early and slowly progressive chronic cases in which there is not any very marked enlargement of bone apparent, and in subacute attacks, that the chief difficulty arises in distinguishing rheumatoid arthritis from rheumatism. The points which may serve as a guide to diagnosis are:

1. From Rheumatism.

(a) In the chronic form, invasion of the small joints first (notably the proximal phalangeal joints of the first and second fingers and the metacarpo-phalangeal joint of the first finger and thumb), fusiform swelling, symmetry of the affection, prevalence in women, affections of the temporo-maxillary articulation and those of the cervical spine, pain along the clavicle, crepitation or grating felt in the joints on movement, muscular atrophy (especially interossei), clamminess of extremities, tendency to spread from small to large joints, anaemia always present, family history of phthisis. Sometimes the first indications to the patient are numbness and tingling in the limbs.

(b) In subacute attacks it may be for the first few days impossible to decide. The small joints are attacked first, without any tendency to rapid migration; the swelling is circumscribed; the symptoms persist, although under treatment; there is little tendency to high temperature curve; there is very little (if any) tendency to endocarditis and pericarditis. Garrod went so far as to consider the absence of cardiac inflammation as one of the most important diagnostic features of rheumatoid arthritis, and said he had never traced either endocarditis or pericarditis in this disease.

2. From Acute Gout.

In gout there is a tendency to commence by sudden pain and swelling, especially of the great toes, with oedema and redness. Rheumatoid arthritis has an insidious onset; it is more common among the poor and ill nourished. Gout is comparatively rare in women: it may be more difficult

to distinguish from chronic gout, but the history will help. The deformities of chronic gout may resemble to some extent those of advanced rheumatoid arthritis, but in gout definite attacks occur from time to time, and usually deposits of sodium urate will be found near the articulation or in other parts, such as the ears or hands. It occurs more frequently in men, and there is little or no tendency to emaciation. In rheumatoid arthritis the temporo-maxillary joint is often affected, and also the joints of the cervical vertebrae, as evidenced by pain and stiffness, and there is symmetrical involvement of the small joints of the hand. In gout these conditions are not present. It is of great importance to distinguish between the two conditions because the treatment is essentially different. A case of rheumatoid arthritis must not be subjected to a régime so necessary in certain forms of gout. There are some cases in which, I believe, the diseases coexist.

3. From Sciatica.

Where the hip-joint alone is affected there is often a resemblance in the symptoms to those of sciatica. A diagnosis can usually be made by careful examination of the part. In rheumatoid arthritis the affected leg cannot be crossed over the other without causing great pain. If the foot is jarred pain is felt in the joint. There may be considerable thickening, due to bony outgrowths, and grating may be felt on rotation. The general pain is referred more to the joint than to the region of the sciatic nerve and down the limb. Charcot's joint disease is thought by some to have the same pathology as rheumatoid arthritis, the suggestion being that the affection is rheumatoid arthritis occurring in a patient debilitated by the cord disease. There is in Charcot's disease no pain in the joint, although there is so much degenerative change that the functions are in abeyance. Monarticular rheumatoid arthritis, usually in one of the larger joints, may simulate a tuberculous affection, and the distinction is at times extremely difficult. The vertebral column is sometimes involved to such a degree that the pain and rigidity may lead to the belief that spinal caries is present, and great care is needed in distinguishing these affections.

Still's disease in children, which occurs mostly in young girls, closely resembles rheumatoid arthritis, and is, possibly, a modified form of the disease; its nature is uncertain. It differs from rheumatoid arthritis, however, in that the spleen is enlarged and also the liver. The lymphatic glands are increased in size, at first near the joints, and later throughout the body. There is defective development, the eyes may be prominent. It is usually a fatal disease, although it may last for years.

TREATMENT.

Although rheumatoid arthritis is a progressive disease, and by some considered incurable, much can be done in the early stages to arrest, and in the more advanced cases

FIG. 1.—Acute case in a boy aged 14. During the first two weeks of treatment the temperature in the evening was usually between 101° and 103°, with morning falls to normal. All the joints more or less affected, and muscular wasting pronounced.

FIG. 2.—Subacute case; boy aged 8. Seven and a half months' duration.

to relieve. It is a disease which seems to attack a constitution debilitated from some cause, and it is of great importance, therefore, to refrain from any kind of lowering treatment, either in the acute or chronic forms. In acute

and subacute cases the patient should be in bed, and an endeavour made to relieve pain by soothing applications, such as lint wrung out of lead and opium lotion. The joints should be kept at rest while acute symptoms last, but as soon as they subside gentle movement should be begun, as there is great tendency in this affection for the joints to become stiff. Splints, if used, should not be kept on continuously. The pain may sometimes be lessened by painting the joints with guaiacol and tincture of iodine in the proportion of 1 of guaiacol to 6 of iodine. Mesotan with olive oil, or a 25 to 50 per cent. ointment with lano-

the swelling. Sometimes extension with weights is soothing and helps to counteract the tendency to flexion so often present; it is specially useful when the pain is severe, as is often the case in the knees, apparently from

rubbing of the ulcerated cartilages one upon another; the weights should not be heavy and should be applied continuously. Fingers which are becoming flexed can be rendered considerably straighter by a suitable splint on the palmar aspect; this should be applied at night and taken off in the morning, so that the fingers

may be moved during the day. Patients should be told to use their joints as much as they can short of giving rise to pain afterwards, also to take exercise in the open air. If the affection is in the joints of the lower limbs, walking is rendered less painful and difficult by the use

FIG. 3.—Chronic case; male. Dislocation, pigmentation, wasting, and deposits.

FIG. 4.—Chronic case: female, aged 45. Marked ulnar deviation, dislocation at metacarpophalangeal joints. Twenty-five years' duration.

FIG. 5.—Chronic case: male, aged 19. Seven years' duration.

line, may be used. Methyl salicylate with three parts of olive oil, or with six parts of tincture of iodine, may be thickly painted over the painful articulation, which should then be covered with lint and oilsilk and lightly bandaged. I have known an icebag give relief when other methods had failed. In chronic cases there is perhaps no more generally useful application to affected joints than blisters, which seldom fail to relieve pain and stiffness so often complained of, and in no joint more successfully than the temporo-maxillary; they should be small, and may be repeated. Sometimes bathing with hot water does good. Midelton advocates the use of continuous counter irritation over the spinal cord, even in the most advanced cases where all treatment may appear to be hopeless, believing that nervous changes are an important factor. The principal methods he uses are (1) blisters followed by savin ointment; (2) acupuncture with counter-irritant drugs such as cantharides, croton oil, or oil of mustard; and (3) the galvano-cautery. When joints are more stiff than painful olive oil may be used for rubbing instead of liniments, especially in children, where weakness of joints is a symptom; or if there are soft swellings, adhesive strapping gives support and comfort and tends to reduce

of an apparatus so constructed with adjustable crutches on wheels that part of the weight of the patient can be transferred from the lower limbs to the axillae and arms. Adhesions are occasionally broken down under an anaesthetic, but the results I have seen have not been

encouraging as most of the joints again became stiff (possibly in some cases owing to neglect by the patients themselves in after-treatment).

Excision, scraping of joint tissues, or merely washing out the joint, in the acute stages, have been tried with a view to arrest the spread of the disease; it is stated that by the removal of the diseased cartilage and synovial membrane of one joint, not only is that joint improved (if not cured) but the other affected joints are also improved.

Diet.

In acute cases the diet should be light, easily assimilated, and nonriching—milk, raw meat juice, broth, eggs, etc.—

and increased to more solid food as the febrile symptoms subside; stimulants may be required. Chronic cases should not be on low diet; this, like phthisis, is a disease in which good feeding is essential. Attempts have been made to discover whether the nature of the food has any bearing upon the severity of the joint symptoms.

FIG. 6.—Chronic case: female, aged 49. Interosseal much wasted, and knuckles thickened. Five years' duration.

The conclusion is that diet has little relationship to the disease; no advantage is to be gained by excluding red meats from the diet; fruits and salads may be taken. Meals should be arranged at regular intervals and should be varied. No hard and fast rule can be laid down, and probably the most generally successful diet is a mixed one. Fats are needed, cod-liver oil, and also milk and cream.

Woollen clothes should be worn at all seasons of the year, and any exposure to cold and wet avoided; the most suitable climate is one which is dry, warm, equable, and sunny. Residence at the seaside is not generally recommended and sometimes seems to aggravate the symptoms of the disease.

Drugs.

In febrile cases antiseptics are indicated, as also in many chronic cases. Guaiacol, creosote, quinine, salol, or salicylates, should be given; they often relieve pain. Sodium salicylate is of most use when there is a history of rheumatism, and if combined with twice as much bicarbonate can be given freely. Aspirin and phenacetin often relieve the pain. Anaemia is always a symptom of the disease and requires treatment. Iron and arsenic are probably the most useful of all drugs for improving the general health. They are best given in combination; the syrup of the iodide of iron is one of the most suitable forms. Potassium iodide is often given for pain at night. For cramps, hyoscyanus or cimicifuga is worth trying. Morphine and opium should be avoided if possible. I have not found it necessary to prescribe either, and their routine use is to be deprecated.

Constipation, which is common, and other digestive troubles require attention. Sulphocarbolate of soda and the antiseptics already mentioned are serviceable. If the stomach is dilated it should be washed out. It is important to remedy any oral sepsis; the teeth must be attended to, but I strongly deprecate indiscriminate extraction. Antiseptic washes should be used freely. Paraldehyde, phenacetin, and bromide may be given for sleeplessness. Where gout is present colchicum and alkalis should be prescribed; an alkaline mixture of quinine is also of service.

The chief advantages claimed for treatment by passive congestion appear to be relief of pain, which is often very marked, and the prevention of stiffness. Pain gives rise to muscular spasm, and this causes stiffness. The relief of the pain by congestion enables the joint to be moved, and this counteracts the tendency to the formation of adhesions. It is also said to promote the resolution of thickening in joints and tendons.

Massage is of value for the relief of pain and in keeping up the nutrition of muscles; it also relieves or prevents stiffness and fixation of joints.

Electricity, in the chronic conditions where there is atrophy and debility and the disease is not in an active state, in the form of a weak continuous current, may be of service. I have used galvanism with some benefit to nutrition and lessening of pain. Electric baths are also useful in certain stages.

Heat almost always relieves pain, and the most efficacious form appears to be the dry radiant heat; the diaphoretic effects of the combination are greatly superior to those of the same degree of non-luminous heat, and the body can bear with this form much higher temperatures than by any other application; a whole body bath can be used at a temperature as high as 300° or 400° F.; with a local bath it may be raised to 500° F. Besides relief to pain, other important changes are effected. Free perspiration is induced over the whole body even although the rays are applied locally, local arterial pressure is diminished, and metabolic processes are increased. Light has the effect of tending to increase the haemoglobin and in this way the anaemia is benefited; the appetite is also improved. The effects of the baths are enhanced if they are followed by massage and the free use of iodex or some other ointment or application of the same kind; adhesions and muscular contractions around joints are softened and relaxed and can be more easily broken down, and in this way some of the most chronic forms can be relieved.

Vaccines have been used, and acute infective cases have been treated by hypodermic injections of antistreptococcal serum. Crowe has found much benefit from the use of vaccine prepared from the *Staphylococcus deformans* in acute rheumatoid arthritis, and in obscure neuritis where

the micro-organism has been shown to be present in the patient's urine. It is at times very difficult to distinguish true rheumatoid arthritis from septic arthritis (gonorrhoea, pyorrhoea, etc.).

If a local suppurative active centre, such as endometritis, erosion of cervix, or possibly a similar condition in the nose or mouth, be present, a culture should be made and a vaccine given. Stock so-called rheumatic vaccines should be avoided.

Wallace and Child advocate the use of an extract of the pituitary body of the ox, prepared in a particular way; 1 c.cm. is given by intramuscular injection, generally every other day. The reports were that the patients so treated were practically crippled before the treatment was begun, all put on weight, the swellings around the joints disappeared, and they could be moved without pain after two or three months of treatment. Roberts also is in favour of the use of glandular extracts in chronic cases, whatever other treatment may be adopted at the same time; he uses, in particular, the thyroid, thymus, and pituitary. The thymus, it is said, acts very slowly, and should be continued for six months before it is given up; it is unsuitable if there has been a rapid increase of weight, because it sometimes stimulates nutrition to an unusual extent.

Baths have long been held in repute; they are chiefly indicated when the disease is in an early stage and the patient in fair general health; they are not advisable in the old or debilitated. The chemical properties of the water used is not a matter of vital importance, the chief point is the mode of application. The objects aimed at are: decrease of pain and stiffness in the joints, a general improvement in the patient's strength and nutrition, increased elimination by the skin, and absorption of the swelling around the joints. My experience convinces me that bathing, with its accompaniments, is a form of treatment which in suitable cases is of the utmost value, and there is not a doubt that, even in some of the most chronic and advanced cases, great relief or permanent benefit is a frequent result. The good effect is greatly enhanced by the internal administration of a mineral water properly prescribed, and although the use of any pure water may be of advantage, it is well known that if a water prepared according to the formula made out from the analysis of a mineral water be drunk, the effects are not at all the same as those obtained by drinking the original water in its natural state.

The advantages of a course at a mineral water spa do not consist only in the special medicinal virtues of the waters used but in the fact that the treatment is carried out with care and skill. The change of air, the modification of diet, and freedom from home cares and worries, are all important adjuncts, and patients should be recommended to visit year after year some health resort where such a régime can be provided. We have in Cheltenham the facilities necessary to carry out such treatment. Especially are we well off in regard to the mineral waters for internal administration, which have been shown by analysis to be superior to most and surpassed by none of their kind at any health resort either in England or abroad. Now is the time, when the foreign spas which have hitherto been so greatly in demand are closed, to make known in every legitimate way the many special advantages offered by our own town.

A great deal has already been accomplished, and efforts are still being made, to advertise the place and render it attractive and wholly efficient for the comfort and entertainment of patients and visitors. Much depends on the medical profession generally to help the undertaking by sending patients here to drink the waters and to undergo the usual courses of treatment which are expected at a spa, and which they can obtain in Cheltenham quite as well as they can at some of the health resorts which are much farther away.

THE Carnegie Foundation has given £200,000 to McGill University, Montreal, in recognition of that institution's "devoted service and sacrifice towards Canada's part in the war." The gift is intended as an expression of the appreciation and sympathy with the people of the Dominion felt by their allies in the United States. A part of the work which has earned this tribute is the maintenance of a general hospital in France with more than 2,000 beds.

AN ESSENTIAL PRINCIPLE IN THE TREATMENT OF GAS GANGRENE.

BY TEMPORARY COLONEL H. M. W. GRAY, C.B.,
M.B.ABERD., F.R.C.S. EDIN.,
CONSULTANT SURGEON, BRITISH EXPEDITIONARY FORCE.

I wish to urge the wide recognition and application of a principle which I believe is essential for the successful prevention and eradication of gas gangrene in war wounds met with in France. My reason for doing so is that I have not seen it definitely mentioned in any writings in the public press. I have recommended it for the past two and a half years, and it becomes daily more evident that the principle is correct.

The causative bacilli of gas gangrene will not develop in tissues which are provided with a vigorous circulation of healthy blood. They thrive best when the circulation is entirely stopped—for example, in a person dead of gas gangrene or in a limb of a living person where the main vessels have been severed. Long application of a tourniquet often allows the infection to obtain a firm hold. Feebleness of circulation in the wounded part, whether from a general cause, such as shock, or from a local cause, such as tension from effused material or pressure of foreign bodies, favours its development. As Major-General Cuthbert Wallace and others have pointed out, these bacilli grow most luxuriantly in devitalized muscle. The injured muscle or group of muscles is deprived, in part or in whole, of its normal blood supply according to whether the missile severs the main nutrient vessels or merely causes isolation of lacerated portions. Pressure in the neighbouring parts, whether caused by effused material in the wound, by inflammatory reaction, or by external constriction, interferes still further with the circulation, and forms a most important arc of the ever-widening vicious circle of spreading inflammation.

From purely clinical observations, then, the principle has been evolved, and it is this: Whether one undertakes preventive, pre-inflammatory operation, or curative operation after the gangrene has developed, success and safety are assured only when the wounded parts are excised until definite bleeding of the cut surface is seen. The bleeding must be definite; it need not be free. In pre-inflammatory operations the use of a tourniquet during operation may be permissible; it is not advisable unless the patient is exsanguinate. In cases where gangrene is already well marked it should not be used. Care must be taken that in excising parts at the later stages of the operation the blood supply of tissues left behind at an earlier part of the operation is not interfered with; therefore, as a rule, proximal parts should be excised before distal parts. It is usually easy to decide, when this principle is kept in view, how much should be excised—whether only part of a muscle, the whole muscle, a group of muscles, or the limb.

Surgeons who base their work on this principle have more success, and have to perform fewer secondary operations than those who do not follow it.

On the successful application of the principle I have enunciated depends the justification of the practice of excision and primary suture of wounds—a procedure which I carried out with gratifying results as far back as November, 1914.¹

A CASE OF PYAEMIA TREATED WITH INTRAVENOUS INJECTIONS OF EUSOL.

BY ROBERT AITKEN, M.D., M.R.C.P.E.,
TEMPORARY SURGEON R.N.

In my opinion there can be no doubt that the intravenous use of eusol saved the life of the patient whose case is here recorded. He was exceedingly ill on the Wednesday when he was admitted, and I did not expect that he would see the end of that week. It was very noticeable how he improved after each injection of eusol, and I have pleasure in adding my testimony as to the value of that remedy.

William C., aged 20, a gunner in the R.G.A., was admitted to the R.N. hospital ship *Plassy* on October 18th, 1916. Ten days earlier he had had tonsillitis which soon cleared up. Four

days before admission he had become feverish again, and marked deafness was present in both ears.

His temperature was 103°, and he complained of pain in the left sterno-clavicular, left shoulder, left wrist, and right ankle joints; all of these were swollen and tender. He was very deaf. There was no pain or tenderness about the ears or mastoid region. The tonsils were slightly congested and enlarged, but he had no pain on swallowing. No other physical signs were made out.

The day after admission the joints were still very painful, and the patient was seriously ill. He was put on tincture of strophanthus and brandy, alternating every two hours. As he seemed to be suffering from a pyaemia he was given that evening an intravenous injection of eusol as recommended by Lorrain Smith¹ (80 c.cm.). The following morning his hearing had slightly improved, and he said that the pain in his joints was easier. Towards evening the pain got worse again, and I gave him another intravenous injection of 100 c.cm. of eusol. He had a fairly comfortable night, his temperature falling steadily for six hours after the injection to 100°, which was the lowest reached since admission. He complained, however, of pain over the right foot.

For the next three days he improved, requiring less assistance, and taking more notice of what was going on in the ward. As the right foot had become more painful and oedematous, an incision was made and the pus present evacuated, the wound being dressed with eusol. Staphylococci and a few streptococci were cultivated from the pus.

The temperature continued high, frequently being 103°, and on the evening of October 24th I gave him another 100 c.cm. of eusol intravenously. Half an hour later he had a rigor; the temperature rose to 105.8° and the pulse to 156. In two hours the temperature had fallen to 98.2° and the patient was feeling comfortable. The following morning there was a marked improvement. He could hear almost ordinary conversational tones from the other end of the bed. The temperature was 97°. The joints were no longer swollen and there was practically no pain or tenderness.

For the next few days he improved and was able to move himself without pain, but he was still very ill. The temperature had been remittent, but now became intermittent. In spite of the tendency of the temperature to fall, dullness began to be noticed on the left side of the chest, and its area increased. On October 30th his chest was aspirated and 105 fluid ounces of thin peapop-like fluid drawn off; this contained both staphylococci and streptococci. He was so ill, however, that I did not consider it advisable that he should be operated on to establish free drainage.

From this time he improved more rapidly, but a few days later his temperature began to rise again and the fluid showed signs of reaccumulating. Accordingly, on November 8th he was again aspirated and 64 fluid ounces of thick creamy pus withdrawn. It contained numerous short chains of streptococci. In view of the more definitely purulent nature of the fluid, it was decided to open the pleural cavity that evening; 25 fluid ounces of pus containing large flakes of lymph, came away. The operation, under local anaesthesia, was well borne. Though there was a copious discharge each time the wound was dressed, the patient's general condition continued to improve, his temperature becoming normal.

On November 10th he was discharged to a shore hospital, where convalescence was soon established, and his further progress was uneventful.

It was my opinion that the original infection came from the tonsils, and I advised him to have them removed. This was done later, and in July he wrote to me saying that his condition was quite satisfactory. Since then he has been passed as fit for general service.

TREATMENT OF PSORIASIS IN THE ARMY.

BY

H. W. BARBER, M.A., M.D., M.R.C.P.,
CAPTAIN R.A.M.C.(T.C.).

The importance of psoriasis as a cause of disability among troops is not great, but men with an extensive eruption require treatment. At the time of writing, out of 1,100 patients admitted to hospital for skin disease, 56 (that is, about 5 per cent.) are being treated for this complaint. In order to return these cases to duty as quickly as possible I have recently adopted the following method, which has afforded more rapid and uniform results than any other that I have yet tried.

1. Treatment of a Generalized Eruption on the Body and Limbs.

The patient attends for treatment twice daily. Every morning he is given a bath, to which on the first two days cresol (1 oz. to an ordinary sized bath) and an alkali

(a handful of sodium or potassium carbonate) are added; on subsequent mornings the cresol is omitted. After the morning bath, and again in the evening, the following ointment is applied to all affected parts from the neck downwards, excepting the genitals;

R Chrysarobin.	gr. 10
Acid. salicylic.	gr. 15
Acid. carbolic.	gr. 10
Zinc oxide	dr. 1½
Lanoline }
Vaseline }
				℞ ad	oz. 1

Throughout the period of treatment a suit of pyjamas is worn next the skin night and day, and thus becomes thoroughly impregnated with the ointment. The patient is inspected by the medical officer at least every second day.

As a rule the ointment is well tolerated, but, should any area of skin become acutely inflamed and tender, the application of the ointment to that part is at once discontinued, and, instead, some soothing preparation, such as Lassar's paste* (to which a little ichthyol may well be added), is kept thickly applied to the affected region. The genitals are throughout protected by Lassar's paste.

At the end of a week, sometimes earlier, the eruption in most cases is to a large extent cleared, whereupon Lassar's paste, containing 10 grains of salicylic acid to the ounce, is applied to the treated parts, to allay irritation and assist desquamation. A clean suit of pyjamas is at the same time issued to the patient, and at this stage a bath on alternate days only is given.

2. Treatment of Resistant Patches.

It will usually be found that a few active patches remain after the greater part of the eruption has disappeared. Such areas are commonly seen on the elbows and knees, wrists and hands, in the hollows just behind the great trochanters, and sometimes elsewhere. In the treatment of these a stronger ointment is employed as follows:

R Chrysarobin.	gr. 20
Acid. salicylic.	gr. 25
Acid. carbolic.	gr. 10
Zinc oxide	dr. 1½
Lanoline }
Vaseline }
				℞ ad	oz. 1

This is rubbed well into the patches twice daily, and is also kept applied to them on lint during the night, providing that the healthy skin immediately surrounding them is not actively inflamed.

3. Treatment of the Scalp and Forehead.

In order to prevent the occurrence of conjunctivitis the chrysarobin ointment is not used for these parts. The hair is cut very short, and the scalp shampooed three times a week. An ointment of the following composition is kept applied by means of lint, or, better, a closely-fitting linen cap:

R Acid. pyrogall.	gr. 10
Acid. salicylic.	gr. 15
Acid. carbolic.	gr. 10
Ung. hyd. ox. flav.	oz. 1

4. Treatment of the Face and Front of the Neck.

As a rule, psoriasis of these regions will yield to zinc ointment containing 10 grains of ammoniated mercury and 20 to 30 grains of salicylic acid. In more resistant cases the pyrogallac acid ointment, as recommended for the scalp, has proved effectual.

5. Internal Treatment.

The external treatment described has up to the present been uniformly successful in clearing even the most extensive eruptions in a comparatively short time. Its object is to render a man fit for duty as quickly as possible; it will not, of course, prevent relapses.

Internal treatment is only adopted in certain cases. As regards diet, probably the most important factor to be considered in the prevention of relapses, it would in most instances seem hardly worth while to attempt to control it, seeing that the patients will return to active service conditions after their discharge from hospital. Florid individuals, however, with an inflamed eruption are kept for

a time on a milk diet, with plenty of fluids, and freely purged, and a mixture containing vinum antimoniale and potassium citrate is prescribed thrice daily. In another class of patient there is evidence of intoxication from some septic focus—frequently, apparently, the mouth. In these cases a thymol mouth-wash is directed to be used several times a day, the sockets of the teeth are cleansed with hydrogen peroxide, the bowels are kept well opened, and a mixture containing dilute hydrochloric acid and nuxvomica is given after meals. After their discharge they are recommended for dental treatment.

Contraindications and Modifications.

Very acute cases, and those in which the eruption is inflamed and angry-looking, should not be treated at once with the chrysarobin ointment. Free purgation and diuresis, a milk diet, and the administration of vinum antimoniale, together with the local application of Lassar's paste containing salicylic acid and ichthyol, form the lines along which treatment should first be directed. When the acuteness of the eruption has subsided the method of treatment already described may be cautiously begun.

No patient who is suffering from boils or other forms of pyoderma should begin the treatment until these have been cured; otherwise very acute dermatitis is apt to be provoked.

Psoriasis is not uncommonly seen in persons of the seborrhoeic diathesis, and impetiginized seborrhoeic eczema of the face, scalp, ears, and neck sometimes coexists with psoriasis of the trunk and limbs. In seborrhoeic subjects not only does the character of the psoriatic eruption differ from that usually seen, but the distribution is apt to be that of a seborrhoeic eczema—that is, the flexures and midline of the back and chest tend to be involved. As seborrhoeic subjects are peculiarly susceptible to all forms of external irritation the treatment of psoriasis in them must be carried out under very careful supervision in order to avoid chrysarobin dermatitis. The following alkaline citrate mixture is very useful in these cases: Sodium citrate gr. 30, potassium carbonate gr. 15, and sodium bicarbonate gr. 15, thrice daily one hour before meals.

CONCLUSIONS.

Although this method of treatment may not appear to differ materially from those usually employed, the fact remains that no other preparation I have ever used has given me nearly such rapid results. This, too, is the experience of my colleagues, all of whom are dermatologists. We are agreed that the carbolic acid, incorporated in the ointment, must have some specific effect. Whether its action is local, or whether it depends on absorption cannot be proved, but it is interesting to note that Kaposi considered that carbolic acid given internally was as effective as arsenic in the treatment of psoriasis. No ill effects have as yet been noted, but, of course, the possibility of renal irritation and carboloria must be considered. For this reason application of the ointment over a wide area must never be continued for longer than a week without a break; fortunately the eruption over the greater part of the body is usually cleared at the end of this period.

Apart from any special virtue of the applications used, I would lay great stress on the thorough supervision of the treatment as a factor in its success.

I wish to express my gratitude to Major MacCormac, R.A.M.C., who has kindly given me every facility for the carrying out of the treatment, and to my colleagues, Captains Semon, Small, Stewart-Smith, and Pellier, for providing me with cases.

ELECTRICAL TREATMENT OF MUSCLES IN "TRENCH FEET."

BY

FLEET SURGEON G. MURRAY LEVICK, R.N.(RET.).

A NUMBER of cases of trench feet have been treated very successfully in the Electrical Department at Tooting Military Orthopaedic Hospital.

At first nearly all the patients were sent from the wards with a request for radiant heat treatment. After a short trial this was abandoned completely. Not only was it no use, but in nearly all cases the patients complained that it increased their pain instead of relieving it. As already

* The formula for compound zinc paste (B.P.C.) for which "Lassar's paste" is a synonym, is as follows: Zinc oxide finely sifted and starch in powder, of each 24 parts; salicylic acid in powder, 2 parts; soft paraffin (white) 50 parts. The salicylic acid may be omitted, but the name "Lassar's paste" is retained.

pointed out by Mr. Jocelyn Swan and others, the application of heat in any form in the more acute stages is contra-indicated, and relief is more likely to be found in cooling applications than in hot baths or radiant heat.

In the later stages, with which we are here concerned, there is functional loss of movement in the intrinsic muscles of the foot, with or without pain and swelling. The muscles have been completely inactive for some time and are wasted. Tissue changes have taken, and are taking, place. In addition to the blood extravasation through the walls of the damaged blood vessels, there has been inflammatory invasion of the surrounding tissues, and the products of this are not removed owing to stagnation in the veins and lymphatics. Massage and passive movements of the foot give much relief and do a great deal of good, and I think that, apart from electrical means, there is no better treatment to adopt, especially if it is carried out after immersion in hot water. In addition to this, however, some means of getting rhythmical contraction of the muscles is urgently called for, as it is the best method for re-establishing lymphatic and blood efflux; if this be left until too late, permanent tissue change will take place, with loss of muscular function, commonly leading to flat-foot.

Method of Application.

The patient sits with his feet in a warm foot-bath, deep enough to rise above his ankles. If it does not cause pain the temperature of the water may be 110° F. If this is painful, lower temperatures may be used.

After a quarter of an hour, water is removed from the bath until only the soles of the feet are covered as they rest flat on the bottom of the bath, the water rising between the toes, but not into the dorsum of the foot.

An indifferent electrode of a faradic circuit is connected to a piece of wet lint which encircles the ankle of the foot to be treated; it is better to do one foot at a time. The active electrode, a carbon plate, is first immersed in the water in front of the toes.

A metronome is in the circuit, making not more than fifty interruptions a minute, and the current is gradually introduced. It will be seen now that rhythmical contraction is taking place in the foot. The action of the interossei and flexors and extensors of the toes can be seen in a remarkably satisfactory manner. The simultaneous action of the opposing sets of muscles is unavoidable, and matters little, because the object in view is attained—namely, a rhythmical contraction and relaxation, with the certainty of increased blood supply, and efflux of blood and lymph from the part.

The stimulus should be weak at first, but it will be found as a rule that a good contraction of the muscles can be borne from the start if the whole of the above technique is followed exactly. The position of the electrode in the water can be adjusted in its relation to the foot, thus allowing a diffusion of the stimulus before it enters the tissues, and a more even application to different parts. Careful watch should be kept on the muscle contractions the whole time, and the treatment should be discontinued as soon as the muscles show signs of fatigue. This point will take longer to reach as the treatment progresses.

Results.

So satisfactory is this method, and so pleasing the appearance of the part, with the parting and closing of the toes by the action of the interossei, that it at once suggests itself as the best method of applying any form of electrical stimulus to the muscles of the feet, for whatever reason. It is highly probable, though hard to prove, that the deeper layers of muscles are all stimulated in some degree. On moving the electrode to the outer side of the foot, the abductor minimi digiti is seen to start rhythmical contraction, and on the inner side the abductor hallucis may be stimulated, and so on.

After this treatment voluntary movement will soon return in most cases, and care should be taken to elicit this as soon as possible. When it is established, regular and carefully selected exercises should be given until the muscles have regained their tone and ready response. Above all things, until tenderness has disappeared from beneath the feet on pressing them to the ground, the patient should not be allowed to walk about the hospital. His first essays in walking should all be carried out under

instruction, as otherwise he will probably develop a bad style, and I have seen cases of flat-foot which I believe to have been acquired in this way.

MEDICAL, SURGICAL, OBSTETRICAL.

MALIGNANT DISEASE AFTER INJURY.

UNDER present war conditions injuries to bone, accompanied or unaccompanied by suppuration, are of relatively great frequency. In addition to bone lesion, such injuries may be associated with extensive cicatrization. In view of the common belief that squamous cell carcinoma is liable to occur in an ulcer or scar of long standing and that sarcoma is liable to supervene on injury to bone, I have examined the records of the Middlesex Hospital in order to obtain some idea of the future chances of the wounded soldier in these two respects.

Out of over 10,000 records of malignant disease less than 1 per cent. are examples of cancer affecting the skin of trunk or limbs. Amongst these, cases of carcinoma arising on scars form a very small proportion and have chiefly been associated with cicatrices from extensive burns. Somewhat allied to this class are rare cases affecting the face where lupus has been treated with x rays, and the less uncommon cases where cancer has developed on the scalp at the seat of a sebaceous cyst of long standing.

Histological diagnosis indicates that sarcoma constitutes about 9 per cent. of all malignant disease, affects practically all regions of the body, and occurs at all ages with fairly uniform distribution. Direct association of sarcoma with injury is not often recorded; when it is stated to have occurred the sarcoma most frequently affected a long bone.

So far as concerns date of onset of the malignant disease after the trauma carcinoma and sarcoma are in marked contrast; "one year since injury" is an average period when sarcoma is said to have followed on injury of a long bone; "twenty years since injury" is an average period when carcinoma develops in a scar.

It will be seen, therefore, that past experience is reassuring; the probability that a given soldier will suffer from malignant disease at the site of his wound is so small that it may be neglected. Nevertheless, the total number of wounds, injuries to bone, and cicatrices will be very considerable, and there can be no doubt that examples of the type of malignant disease under consideration will not be infrequent in coming years.

GUNSHOT WOUND OF ABDOMEN IN A BOY.

A BOY, aged 6, was admitted to the Royal Devon and Exeter Hospital on the evening of November 19th, having been brought from Chagford in a motor car. With other children he had been playing with a loaded rook rifle when it went off; the bullet entered his abdomen on the right side of the umbilicus, and was evidently directed upwards. On admission the child was very collapsed and his clothing saturated with blood.

He was taken to the theatre and anaesthetized; the abdomen was washed with methylated ether and painted with tincture of iodine. An incision about 4 in. long was made to include the entry wound, from which blood was flowing freely. On opening the abdomen the lower part was found full of blood, which was wiped out and the pelvis packed with gauze; the coils of small intestine were then in turn taken out of the abdomen on to hot Cripps pads and the wounds in the small intestine sought for and in turn sutured; there were sixteen wounds, and from some of them portions of food and blood clot were protruding; the last hole was in the left mesocolon. The operation wound was sutured in layers and closed and the child put back to bed. A normal saline enema with glucose was ordered every six hours. As the last coil of the ileum was being returned a very long and slightly inflamed appendix made its appearance; to avoid possible future trouble this was removed in the usual way.

The temperature was 100.8°; it rose on the next day to 101.6°, and on the evening of the third day to 103°, but the next morning it fell to 100°, and did not afterwards rise above 99° except on the seventh day, when all external stitches were removed. On this day the child was observed to have some irritation posteriorly in the left loin; a hard point which could be felt under the skin was cut down upon and a small rifle bullet easily extracted.

The child made a good recovery, and was discharged cured on January 12th no whit the worse for his experience.

EDWARD J. DONVILLE,
Consulting Surgeon and House-Surgeon,
Royal Devon and Exeter Hospital.

AN ERRANT RABBIT BONE.

The report on February 2nd, 1918, p. 166, of an errant fish-bone by Dr. I. David of Colombo brings to mind a similar incident in which a rabbit bone was concerned. I attended a gentleman, aged about 50, in March, 1882, on account of a swelling in the left iliac fossa, with symptoms of colic. A week later I found him still in bed with a temperature of 104°, when he was suddenly seized in my presence with vomiting and purging. Although enjoined by me to stay in bed he went to business next day and considered himself well.

Some months after, the late Mr. Reginald Harrison read at the Liverpool Medical Institution¹ a case in which a rabbit bone had passed by the urethra. On asking Mr. Harrison for particulars I found we had both had to do with the same person. It seems that in April, 1882, this gentleman was seen by Mr. Harrison on account of a large swelling at the base of the bladder, irritability of that organ, pus in the urine, and the escape of gas bubbles at the end of micturition. Later, in the urinary deposit striped muscular fibres were found. Early in June, 1882, he reported himself greatly better after the passage by the urethra of a bean-like body $\frac{3}{4}$ in. long, which he brought to Mr. Harrison and had taken for a stone. This on being cleaned proved to be part of a rabbit's femur. Gas bubbles continued to issue for a few months, but during the following year he became quite well.

It is evident that during my attendance the bowel was undergoing perforation and adhesion to the bladder, with a toxic "crisis" evinced by the vomiting and diarrhoea. Later the perforation of bladder and the formation of a vesico-intestinal fistula were proved by the presence in the urine of striped muscular fibres derived from food. No particular date was given on which the patient had eaten rabbit, which, however, he often did.

Mr. Harrison in his report also quoted two similar cases: (1) a swallowed hair pin passed by the urethra as a calculus, of which it formed the nucleus;² and (2) a swallowed piece of slate pencil removed from the bladder by lithotomy.³

Reports of Societies.

PURPURA AND HAEMOPHILIA.

At a meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine on March 22nd, Dr. ROBERT HUTCHISON being in the chair, Major W. PALMER LUCAS, Professor of Pediatrics at the University of California, spoke of clinical experiments he had carried out according to the methods described by Dr. W. H. Howell, Professor of Physiology at the Johns Hopkins Hospital. Three factors were essential to clotting: (1) Prothrombin, (2) thrombin elements, and (3) the substance known as antithrombin, which held the blood in solution. If the coagulability of the blood were decreased there was either an increase of antithrombin (as in cases of purpura due to streptococcal infection and in some cases of jaundice), or a decrease of prothrombin. This occurred in most cases of purpura and in haemophilia. In Henoch's purpura, for instance, prothrombin was decreased during an attack; the decrease was very marked, and the amount of prothrombin

present was always below normal. In blood transfusion for purpura he preferred whole blood to serum, as in some serums there was an excess of antithrombin. Good results had been obtained from blood transfusion in purpura, but in haemophilia he had not been able to raise the prothrombin factor enough to obtain success. He usually depended upon rest and local treatment. Haemophiliacs usually bled up to a certain point and then stopped. If the blood were examined at once (and it was very difficult to get a sample at this time) the factors were practically in the normal condition. The whole factor in coagulation was the balance between prothrombin and antithrombin. Replying to questions, Major Lucas said it was not advisable to employ the method in private homes. A hospital laboratory was required. Kephalin was not by any means a panacea. He had used it on haemophiliacs, but it had not had much effect. There were, he said, two types of the haemorrhagic disease of the newly born: (1) in which the antithrombin factor was increased—the septic cases belonged to this type, and the mortality was very high on this account; (2) in which there was diminution in the amount of prothrombin. In one case recovery followed whole blood transfusion. So far he had done no work on syphilitic cases. The reason for the want of balance between prothrombin and antithrombin was at present being worked at, but, so far, analyses had given no results. The investigation was difficult on account of the number of tissues that had to be analysed. In rheumatic purpura prothrombin was usually deficient. He had noticed that haemophilic patients were often able to predict the moment of recovery. This was especially so in the case of children, who often announced that they were "now going to get quite all right," even though there appeared to be no change in the condition. It was often possible to tell the moment of recovery even from the facial expression.

VALUE OF X-RAY TREATMENT.

At a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland, on February 15th, Dr. W. G. HARVEY, Major R.A.M.C.(T.C.), assistant physician and in charge of X-ray Department, Adelaide Hospital, Dublin, gave an estimate of the value of x-ray treatment in various conditions, founded upon an experience of over 500 cases. His observations were summarized as follows:

1. Ringworm. In this the rays were used as an epilating agent. A fortnight after a proper dose of x rays the irradiated area shed all its hair, healthy and parasitic, while some three months later a new growth of hair, free from the parasite, occurred. This treatment was the best for the cure of ringworm. It was certain, painless and rapid, and left the child free from infection within a month of starting. There were, however, many technical points which required attention, or accidents—for example, alopecia—might occur.
2. The results in favus theoretically should be equally good, but such cases often became reinfect.
3. Rodent ulcers in general did well, unless the periosteum or cartilage were involved. True epithelioma were more variable, but many responded well to x rays.
4. Epithelioma on a lupus site should never be treated with x rays—the results were very bad.
5. Warts—senile and juvenile—were amenable to x-ray treatment. Four cases of warty growths on the feet did well.
6. Keloid was satisfactory in its response to x rays.
7. Lupus did well, but the cosmetic results of Finsen light were probably better. Tuberculin injections appeared to favour the treatment.
8. Lupus erythematosus was not benefited.
9. The results with tuberculous glands had not been all that was to be desired.
10. Actinomycosis (one case) was not affected. In the treatment of neoplasms and deep-lying tissues much improvement had been obtained since the methods of "filtration" and "cross fire" were introduced.
11. The symptoms of Graves's disease subsided under x rays. No considerable benefit was derived in simple goitre.
12. Malignant tumours, whenever possible, should be surgically removed. When that was impossible x rays might occasionally bring about a cure, and frequently relieved pain and diminished the tumour.
13. Uterine myomata and enlarged prostates required massive doses of x rays, but with them appeared to do well.

In the discussion which followed Dr. MOORHEAD said that he looked on x rays as a specific in the treatment of Graves's disease, but Dr. CROFTON raised the question whether there might not be danger of thyroid insufficiency following the treatment.

TREATMENT OF TUBAL STERILITY.

At a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, on February 22nd, Dr. HASTINGS TWEEDY read a paper on the cure of sterility by means of catgut strands passed through the Fallopian tube into the uterus, and showed a specimen of ectopic gestation removed from a tube which had been resected on two previous occasions. On the second occasion catgut was placed in position; the specimen showed a free passage to spermatozoa. He attributed the tubal pregnancy to the irritative effect of chromicized catgut, and held that some less harmful material must be employed in future. He described a method which would make it possible to pass silkworm gut through the tube, and to remove this gut in three or four days by the extraction from the uterus of a plug of iodoform gauze. He maintained that the first three days constituted the critical period for the keeping open of the tube after resection, and said that in 50 per cent. of women, sterile in spite of curettage and other local treatment, the sterility resulted from occlusion of the tubes.

Dr. BETHEL SOLOMONS read notes of a case of extra-uterine pregnancy resulting after resection of the tube and insertion of catgut to keep it open. The patient had had five children, and sought advice because she had not become pregnant for four years. A retroverted uterus with salpingitis was found. The left tube was resected and chromic catgut No. 4 inserted in the lumen. The right tube was dilated with air, and a Gillian operation was performed. Two months later a left tubal pregnancy of five weeks' duration was removed. Dr. Solomons considered the insertion of catgut in the tube to keep it open after resection to be a rational procedure. He doubted if chromic catgut made tubal pregnancy more likely; he was of opinion that when this occurred it was due to an uncured salpingitis.

The PRESIDENT of the Academy said that it was probable that some peristalsis occurred in a healthy tube, having regard to its structure, but it had not yet been demonstrated. He was inclined to question the soundness of the view that a piece of gut placed in the lumen of the tube had any irritant action.

Dr. FITZGIBBON said the idea of passing something down the Fallopian tubes to act as a bougie and maintain their patency was an advance in the treatment of tubal sterility. It was impossible at present to judge the efficacy of the method, and even the methods of clearing the tube of adhesions and kinks gave a certain number of good results. He thought the clearing of the fimbriated end the main thing in the operation, and if this were feasible and the fimbriae in good condition, satisfactory results might be expected in a fair number of cases, without the resection of any part of the isthmus of the tube, except where there was marked disease.

The President of the Section (Dr. ALFRED SMITH) considered that a hydrosalpinx where there was little interstitial hypertrophy gave best results in salpingostomy. Where there was much interstitial hypertrophy it seemed hopeless to operate. He recalled cases where healthy children were born after salpingostomy. He was not quite satisfied with insufflation as a test of the permeability of the tube, and preferred the injection of warm saline through the uterus by the Bozeman catheter. In this method the return flow was blocked by the finger; this raised the tension within the uterus and, if the tube were permeable, forced the saline through the tube in droplets. The catgut bougie was not convincing; it might, however, make a useful splint to ensure accurate adaptation in the end-to-end anastomosis.

WE have received the first number of the *Revista del Instituto Bacteriológico del Departamento Nacional de Higiene* of Buenos Aires, in which work done in the laboratories of the institute is to be published. It will also serve as a central organ for the work of researchers on microbiology, hygiene, and experimental medicine, published in Spanish America. The new review is a handsome volume, and the first number contains, among other papers, communications on the specific precipitating properties of anti-snake-venom serums by B. A. Houssay and J. Negrete; studies on experimental poliomyelitis by R. Kraus and L. Kantor, and on the antigen of the mistagmine reaction in malignant tumours by A. H. Roffo.

Rebichus.

WOUNDS OF PLEURA AND LUNG.

ONE of the most recent additions to the Collection Horizon is a well balanced work on wounds of the pleura and lung by a surgeon, Professor GRÉGOIRE, and a physician, M. COURCOUX, both members of the staff of the Paris hospitals.¹ The book is of special interest in connexion with the burning question, referred to in the review of Pierre Duval's book on war wounds of the lung (vide *BRITISH MEDICAL JOURNAL*, 1917, ii, 420), of the advisability of early surgical interference to prevent rapid death from intrapleural haemorrhage. In their full discussion of this problem the authors point out the danger of moving such patients, and the practical difficulties of operating in such cases near the front. One of the questions that have to be answered is whether or no haemorrhage has stopped. On this fact they maintain that coagulation of blood withdrawn from the chest by an exploring syringe is evidence that bleeding is going on, and that operation should be undertaken; on the other hand, if the blood does not clot it may be concluded that the haemorrhage has ceased and that operation is unnecessary. While generally in favour of tapping a sterile haemothorax, the authors recommend waiting a week, as a rule, and do not advise the introduction of air or oxygen to prevent too rapid expansion of the injured lung. A raised temperature associated with an increased number of leucocytes in the blood withdrawn from the pleura does not, in the absence of obvious pus, justify the opinion that the haemothorax has been infected. These conclusions depend on the interesting account given of the changes undergone by the blood in the pleural cavity. The blood, which is usually derived from the lung rather than from the chest wall, does not coagulate unless the pleura is infected or its endothelium damaged, and further, after about five hours it does not coagulate outside the body. There appears to be some anticoagulating agent present, as this blood prevents coagulation in blood added to it. At first the intrapleural blood contains an excess of polymorphonuclear leucocytes, but about the sixth day 60 per cent. of the leucocytes are eosinophils, and macrophages are present. Haemolysis occurs and bilirubin appears, thus confirming the extrahepatic formation of bile pigment.

The work is divided into sections on (a) uninfected wounds, (b) infected wounds, and (c) their sequels. Analysis of over 50,000 war wounds shows that 5 per cent. are of the chest, and that, in contrast to others, those of the chest are relatively seldom infected—in about 15 per cent. The lung is not a favourable site for the growth of the anaërobic *Bacillus welchii*, but this infection, when it does occur, is almost always fatal. Infection on or soon after the fourth day leading to empyema proves fatal in about half the cases. Pneumonia and bronchopneumonia, very rare indeed in association with sterile haemothorax, occur in some of the infected cases and render the outlook extremely grave. The fear that pulmonary tuberculosis may be induced by these chest wounds is shown to be unfounded.

MINOR MALADIES.

THE fourth edition of Dr. LEONARD WILLIAMS's arresting little book on *Minor Maladies*,² revised, enlarged, and brought up to date in medical outlook, is a volume of interest to all practitioners of medicine. Combining as it does both nutritive and irritant properties in a high degree, it forces the reader to think; and, whether he agrees with all he finds in it or not, he will arise from its perusal stimulated, informed, and amused. In the present edition the author lays stress on the study of the internal secretions, and of their influence on the course and causation of health and disease. The future of medicine lies with the endocrine glands, just as its immediate past was ruled by bacteriology. So the author; and he makes out an excellent case for his views in the ten chapters into which his book is divided. The longest of these is that devoted to "goutiness," a term used as the equivalent of "insufficient

or perverted metabolism." Lack of space unfortunately prevents us from following the author into the ramifications of this protean disorder. We wish this interesting and well-written little book the wide popularity it deserves.

THE JEWISH CHILD.

DR. FELDMAN'S book, *The Jewish Child*,³ is the work of one well skilled in the ancient learning and familiar with the traditional beliefs and customs of the Jews, but equally at home in the sphere of rational medicine. He traces the teaching of the Jews as to heredity and eugenics, marriage, pregnancy, embryology, birth, childhood, and adolescence through the Bible and the Talmud, and compares it with the results of modern research. Bacon speaks contemptuously of the fables of the Talmud, and Lightfoot, who gave his life to its study, was disgusted by the *stupenda inanitas* of its contents. In that strange medley of legend and mystical lore, however, there is not a little practical wisdom besides some shadowy anticipations of doctrines now established on a scientific basis. If Dr. Feldman has not altogether escaped the danger that besets such inquiries of reading deeper meanings into old texts than can fairly be found in them, his interpretations are always ingenious and plausible.

The importance attached by the Jews to everything that concerns the begetting and rearing of offspring is thought to have played a part in conserving and increasing the vitality of the race. It was the ideal of the Jews to produce and perpetuate healthy, beautiful, and capable men and women. The influence of injurious conditions in the parent was recognized. The Talmud says that children begotten in drunkenness are mentally deficient; marked difference in age between persons wishing to marry was regarded with disfavour, and the union of imbeciles was discouraged as likely to result in the propagation of imbecility. Midwives are often mentioned in the Talmud, and some of them seem to have been possessed of considerable skill. Caesarean section was performed on the dead mother, and sometimes on the living. Men were forbidden to use measures to prevent procreation, but women were allowed to do so when pregnancy involved danger to the mother or the child. Recourse could even be had to ovariectomy or hysterectomy to produce sterility. Breast feeding was regarded as imperative unless the mother was in bad health. In Talmudic times a child was sent to school at the age of 6. The buildings were lofty and well ventilated, and there is mention of open-air schools. The higher education does not seem to have been open to girls; according to the Talmud the only accomplishment suitable for them was spinning. The child was carefully studied in order to discover what teaching was best suited to its individual powers. It was held that in elementary classes too many subjects should not be taught at once. The strap might be lightly used for the punishment of stubbornness and inattention. Great stress has always been laid on cleanliness of the body, and the public baths were regarded as second in importance only to synagogues and schools. Contrary to popular belief the birth-rate among Jews is lower than that of the general population; they bring fewer children into the world but rear more to maturity. Jewish mothers are more careful than the average Christian of the health of their children. Infant mortality among Jews is at all ages considerably lower than among Gentiles, and the chances of surviving the first critical year are much greater. Illegitimate births are much fewer. Statistics from various sources show that, age for age, Jewish children are as a rule shorter and lighter than the non-Jewish, and have a smaller chest measurement.

Dr. Feldman's book is full of interesting matter, and his use of the facts which he has gathered from the most varied sources is suggestive if not always convincing. He has made a valuable contribution to the study of a people which, under many disadvantages, has written its mark deep on human history. Were military predominance the vital principle of an enduring national prosperity the Jewish race would have perished long ago. One of the secrets of their preservation is the loving care lavished on their children, and this regard for the welfare of the future

citizens affords the best hope for the success of the interesting experiment which is now, thanks to British statesmanship and British arms, about to be tried in Palestine.

NOTES ON BOOKS.

DR. LACHLAN GRANT of Ballachulish has reprinted from the *Caledonian Medical Journal* an address on *Keeping Fit*, delivered to the guard of the German prisoners of war while he was acting as medical officer to the prisoners of war camp, Kinlochleven.⁴ It is a summary in simple language of the laws of bodily and mental hygiene. There is much sound advice as to food. The Roman soldier conquered the world on a diet of ground corn boiled in water, and on campaign Caesar shared the fare of his men. Mark Antony had been daintily brought up, yet, when the occasion called for self-denial, he drank "puddle water," and ate the barks of trees and "such beasts as never man tasted of their flesh before"; and this "was borne so like a soldier that (his) cheek so much as lank'd not"; but all men are not cast in this heroic mould. Dr. Lachlan Grant rightly insists that, in order to keep fit, mental control and moral discipline are necessary in addition to physical culture. The will may be strengthened by practice in right thinking—that is, resolutely looking at things in their true perspective and not suffering oneself to be disturbed by every rumour or scared by any of the inevitable reverses that occur in every war. Hannibal, Caesar, Napoleon, Nelson, Wellington, and other great commanders had their full share of such misadventures, and were denounced as incompetent by the pessimists of their day. We should, in Dr. Grant's words, "guard our thoughts against what may be termed the deleterious microbes of the mind which tend to maim our mental control." Moral discipline, which means the adjustment of one's conduct and emotions to the promotion of the highest interests of the community, is a vital factor in the maintenance of fitness in the individual as in the nation as a whole. In the recognition and application of this truth lies the hope of restoring civilization and building a new and better world on the ruins left by the devastating hand of war.

FOODSTUFFS FOR PATHOLOGICAL LABORATORIES.

THE Medical Research Committee has recently brought to the notice of Lord Rhondda the special difficulties confronting the directors of pathological and other scientific laboratories in the regulations relating to food supply. Many instances have been brought to the notice of the Committee in which scientific work of the highest national importance has been endangered by difficulties, under existing conditions, in obtaining necessary foodstuffs in sufficient amount or variety, though the total amount required is quite negligible in relation to the general food supply.

The Ministry of Food has now issued the following memorandum for the guidance of Food Control Committees:

Food Office Instruction No. 15.

MINISTRY OF FOOD.

MEMORANDUM FOR THE GUIDANCE OF FOOD CONTROL COMMITTEES.

Supplies of Foodstuffs to Pathological Laboratories.

1. Lord Rhondda's attention has been called to the difficulties experienced by scientific laboratories in obtaining the small quantities of foodstuffs required by them for the purposes of their scientific work.

2. These laboratories throughout the country are engaged on work of the greatest importance both for civilian medical practice and for the maintenance of the health of the Navy and Army.

3. The Food Controller is authorizing laboratories duly licensed by the Home Office under Act 39 and 40 Victoria, cap. 77, to obtain supplies of any rationed article on production to the supplier of a certificate signed on behalf of a laboratory to the effect that they are necessary for the purposes described above. In due course special Order Forms will be issued to such laboratories for this purpose. Committees should also assist such laboratories in obtaining necessary supplies of unrationed foodstuffs in case they experience difficulty in securing them.

4. A statutory order will shortly be issued by the Ministry of Food exempting from the provisions of the Food Controller's Orders the use of grain and other foodstuffs in any such licensed laboratories for the maintenance of animals or for the preparation of laboratory materials.

SATURDAY, MARCH 30TH, 1918.

MEDICAL REINFORCEMENTS FOR THE WESTERN FRONT.

AN APPEAL BY THE MINISTRY OF NATIONAL
SERVICE.

THE result of the concentrated German attack on the southern part of the Western Front from a point south of Arras to La Fère may have disappointed the enemy's hopes, but it has disappointed also the expectation of the British Command that it would be possible to hold a line considerably to the east of the Somme.

The country fully understands the position, particularly the threat to Amiens by the approach to Albert. The enemy claim that during the first five days (March 21st to March 25th) they took 45,000 prisoners, besides guns and great stores of supplies. This claim has not been denied by the War Office; in that total must be included many medical officers not only of the battalions, but also of field ambulances and probably some casualty clearing stations. The fighting throughout the area, both where most and least ground has been yielded, is officially described as very severe, and it is certain that the number of casualties to be treated by the British Army Medical Service, even allowing that many wounded fell in areas overrun by the enemy, and are now prisoners, must be very large.

The emergency is so great that the Ministry of National Service makes an urgent appeal to members of the medical profession to come forward with offers of voluntary service to meet the existing pressure. The appeal is made—

First, to medical men now in this country who have relinquished their commissions and have not rejoined. Their services are immediately and urgently required with the armies in France.

Secondly, an appeal is made to medical men under the age of 55 who are physically fit to offer their services either at home or abroad.

The statutory Professional Committees have the practical aspects of the matter under close consideration, and are working in immediate touch with the Ministry of National Service. We understand that a letter conveying this appeal and stating the conditions of service proposed will be sent to all medical men who are believed to be in a position to respond.

We are aware that the number of men in these categories who can be available is small, and we know that in many areas the number of civilian practitioners has been reduced to a level which has caused anxiety to civilian authorities; but the situation which has to be faced is serious, and we are confident that the volutary spirit of medical men will face it. Every one of them who responds immediately will be performing an act of practical patriotism as well as of individual fortitude.

THE DEMAND FOR AN INCREASED CAPITATION FEE.

THE main business of the special conference of representatives of Local Medical and Panel Committees, to be held on April 11th at the Connaught Rooms, will be to consider the position with regard to the demand for an increased capitation fee put forward by the last annual conference, and the unfavourable reply thereto of the Chairman of the National Health Insurance Joint Committee. The Insurance Acts Committee was instructed to press for an increase in the capitation fee from 7s. to 10s., this sum to cover the increased liabilities in respect of discharged disabled soldiers and sailors and all services now rendered to tuberculous patients by panel practitioners. The decision of the conference was conveyed by letter to the Insurance Commissioners early in November; a deputation waited on the Commissioners ten days later, and on December 8th a memorandum* setting out the reasons for the demand was forwarded to Sir Edwin Cornwall. On February 19th the Insurance Acts Committee had an interview with the Insurance Commissioners, when Sir Edwin Cornwall, in his capacity as chairman of the Joint Committee, read a long statement, which in substance amounted to a refusal to grant any general increase in the capitation rate to insurance practitioners. Sir Edwin Cornwall had spoken of receiving a deputation to discuss the whole subject with him personally, but, in fact, his reply had already been printed; the interview, for all practical purposes, was merely an occasion for hearing this White Paper read. Every insurance practitioner has now had an opportunity of studying the correspondence which has passed between the Insurance Acts Committee and the Commissioners, including the full text of Sir Edwin Cornwall's statement and of the reply the Insurance Acts Committee had since prepared. The gist of the Government's decision is conveyed in certain passages which may be lifted from Sir Edwin Cornwall's statement without injury to the context. In choosing them we have passed over the debating points and irrelevances with which the refusal is padded out.

Dealing with the effect of war conditions on the doctor's liability for attendance, the conclusion is that "it is difficult in the absence of positive evidence to accept the view that there has been such an actual increase in the amount of medical attendance required per head of the insured as to justify the sanction of the Government being sought for any increase in the capitation rate based upon this ground." Dealing next with the contention that the rise in the cost of living and of the expenses of practice has lowered the effective remuneration of insurance practitioners: "the Minister can only treat the application as one put forward, on war grounds solely, for a general and uniform increase of remuneration to the extent of 3s. per insured person per annum—that is, an increase of over 42 per cent. on the present remuneration—to all doctors engaged in National Health Insurance work, without discrimination of any kind between the circumstances of one insurance practitioner and those of another. He is compelled to say that he considers that the application if so presented is not one which the Government could entertain or which it is likely that Parliament would be willing to concede."

This decision is defended on two grounds: First, that expenses of practice admittedly vary widely in different practices, and that the increase in such

* SUPPLEMENT, December 22nd, 1917, p. 123.

expenses due to war conditions is also variable; hence, "no uniform increase of remuneration to *all* insurance practitioners would be a proper method of compensating practitioners affected so diversely." Secondly, such an application must be examined "not as one specially affecting insurance administration, but as related to similar applications from other sections of the community, and therefore to be decided in accordance with the general policy of the Government in dealing with applications of the kind. . . . Such grants as have been made in consideration of hardships produced by the rise in prices have taken careful account of the incomes of the persons in question, and the principle underlying them has been that of mitigating hardship in the case of those persons whose incomes are small. . . . In view of all these considerations, the Government would not be justified in asking Parliament to make, in respect of the increased cost of living, a grant which should apply *uniformly to all insurance practitioners without discrimination*, as proposed by the conference." While, however, Sir Edwin Cornwall could not entertain the application as submitted to him, he professed himself willing to examine a detailed case, if put forward with adequate confirmatory evidence, dealing with hardships due to the increased cost of practice expenses and the increased cost of living. Concerning practice expenses—especially travelling—any case put forward for a suitable grant to meet hardships in this respect was to be supported by the necessary evidence as to the actual amount of hardship thus entailed upon practitioners of different types, and accompanied by suggestions for the equitable distribution of such grants.

The Insurance Acts Committee, believing that this answer if it stood alone would not satisfy the medical profession, asked the Chancellor of the Exchequer to make some authoritative pronouncement as to the general Government policy in regard to applications for increased remuneration. Mr. Bonar Law accordingly received a deputation upon this matter on March 15th, and an agreed report of the proceedings has been issued to insurance practitioners. The Chancellor discussed the claim for an increased capitation fee for insurance practitioners under two heads: (1) in respect of increased out-of-pocket expenses; and (2) on the ground of the higher cost of living. He thought the first point reasonable, but difficult to meet, because the extra cost to doctors must vary very much according to the nature of their practices; he added, however, that if the profession could submit an equitable scheme for meeting these increased expenses the Treasury would be prepared to consider it. He would not accept the second contention. In giving war bonuses to many of the wage-earning classes the Government had made no distinction in respect of income, because this distinction was impracticable; otherwise it would have been right to discriminate between high wage earners and the others. In the case of medical practitioners he could not approve a uniform increase, since the cost of the necessities of life had risen just as much for the man with a low income as for the man with a high income. He was sure Parliament would not agree to an increase for all doctors irrespective of their incomes, but he promised that the Treasury would consider sympathetically a scheme based on the principle that doctors with small incomes should get some increase on the ground of the higher cost of living. He explained that in dealing with any such claim an income limit of £500 would apply to insurance practitioners, the net professional income being taken as the basis, and it would not be necessary to deal with each case

individually, but to take classes of practitioners and different kinds of areas. He was not, he said, prepared to consider any general increase—even a small one—on account of the changed conditions and consequent alterations in the liabilities of insurance practitioners due to the war. He declined also to undertake any partial revision of the general conditions in order to meet the special claims of rural doctors; that, he said, must wait until the general revision. But the Treasury was willing to meet fairly any actual increase in out-of-pocket expenses, claims for which would probably come mainly from rural practitioners.

All the documents are now in the hands, not only of Local Medical and Panel Committees, but of their constituents. The case for an increased general capitation fee has been argued by the Insurance Acts Committee, and the Government has given its reply through the mouths of the Chairman of the National Health Insurance Joint Committee and the Chancellor of the Exchequer. The forthcoming conference will decide what is to be done next. In giving their decision the representatives will, no doubt, bear in mind the circumstances of the present moment.

"PANCREATIC INSUFFICIENCY": COELIAC DISEASE.

ACCORDING to the general regulations permitting invalids to have food in excess of the compulsory rations, reproduced on page 290 of our issue of March 9th, extra meat and fat may be allowed to patients suffering from diabetes, tuberculosis, coeliac disease, and pancreatic insufficiency. The two last conditions were added at the instance of the Scientific Adviser (Sir H. Thompson) after consultation with one of the medical referees to the Ministry of Food, and were not among those recommended by the Committee of Reference of the Royal Colleges of Physicians and Surgeons and the Central Medical War Committee. As is not unnatural, some difficulty has been experienced in connexion with these two additional justifications for a mere liberal diet, and especially with regard to pancreatic insufficiency. As diabetes is separately mentioned, it appears that carbohydrate inadequacy of the pancreas is not referred to, and we are therefore left with pancreatic failure to deal with fats and proteins. For the detection of failure to digest proteins laboratory methods, such as Schmidt's nuclein test or Sahli's iodoform capsules, would be necessary, and it seems fair to assume that in ordinary practice "pancreatic insufficiency" would be confined to and based on the presence of large quantities of undigested fat in the stools without jaundice, for the occurrence of pancreatic infantilism, as described by Dr. Byrom Bramwell, is a curiosity too rare to be taken into account. Steatorrhoea, though long known to be associated with pancreatic disease, may occur in other conditions, such as intestinal catarrh and sprue, and to determine both a real excess of fats in the faeces and the cause of the steatorrhoea laboratory tests, quantitative and qualitative, such as those devised by Cammidge, are strictly speaking desirable, but obviously are not practicable in the majority of cases. In ordinary practice "pancreatic insufficiency" will therefore probably be based on the naked eye diagnosis of fatty stools; this leaves a not inconsiderable loophole for error, and it is perhaps a pity that the term "pancreatic insufficiency," which does not appear in the last edition of the *Nomenclature of Disease* (1906) and from a clinical point of view is wanting in clearness and definition, should have been introduced. It might, indeed, have been better to have been content with "excess of fat in the stools"; and, as at present ordained, some statement of the grounds on which this diagnosis is made should be required before the permit is granted. The coeliac disease, described by the late Samuel Gee

in *St. Bartholomew's Hospital Reports* for 1888, is better recognized; Dr. R. Hutchison contributed the article on it to Garrod, Batten, and Thursfield's *Diseases of Children* (1913), Sir W. Osler has given it his imprimatur, and Professor Still has taken it as his subject for the current Lumsden lectures before the Royal College of Physicians; but it did not appear in the *Nomenclature of Disease* (1906). Clinically it is a diarrhoea, mainly of children, characterized by bulky pale stools with the consistency of porridge; etiologically it has been variously connected with disease of the pancreas, of the liver (Cheadle's "acholia"), or with a special intestinal infection (C. A. Herter). From the point of view of treatment, raw or underdone meat, as much as 6 oz. daily for a child of 4 years, is recommended; and this practical consideration, taken in conjunction with its fairly definite clinical features, makes its inclusion less open to question than that of pancreatic insufficiency.

POST-OPERATIVE PNEUMONITIS.

By pneumonia Whipple¹ means not necessarily pneumonia, but a condition of the lung recognized in 1848, and called, after its describer, Woillez's disease by the French. The lung shows engorgement of the capillaries and exudation into the alveoli of mucus, red blood, epithelial, eosinophil, and mononuclear cells, but no fibrin. As a post-operative event this change is much commoner than is generally thought, and is often dismissed under the casual term "post-operative reaction." Among 3,719 operations at the Presbyterian Hospital, New York, during 1915-16, when this subject was being specially investigated, it was detected in 97 cases, 88 being laparotomies. The most important disposing factors are recent or concurrent inflammation of some part of the respiratory tract, pulmonary congestion, inhibition of the normal respiratory movements by the pain of the abdominal incision, by distension or tight bandaging, debility, sepsis, and cachexia, and increased numbers and virulence of the pneumococcus during the winter and early spring. Five of the cases were regarded as embolic pneumonia, but in no instance was this proved by examination after death, and the widespread belief that post-operative pneumonia is generally embolic is not accepted. Neither can the anaesthesia be regarded as solely responsible, for the cases of pneumonia may show a higher percentage incidence among cases under local than among those under general anaesthesia. Ether, however, is especially irritating to the oropharynx, and so should never be given to a patient with "a cold." The infective agent is in most of the cases—in 46 out of 69 examined—pneumococcus Type IV,² a saprophyte in 60 per cent. of throats, responsible for a short, atypical, and mild form of pneumonia. Fourteen cases showed pneumococci of other (I, II, III) types, and five the influenza bacillus. As a rule there is no initial rigor, no rusty sputum, no sustained high temperature for five to seven days, no severe toxæmia, or alarming symptoms terminating by crisis. The symptoms come on within forty-eight hours of the operation with a sharp rise of temperature to 102° or 104° F., cough, increased respirations, pain, though rarely severe, in the side, more often the right, and usually dullness over the base of one lung; but bronchial breathing does not appear for another two days, and then after another day the fever goes by lysis. Skiagraphy is a valuable means of diagnosis in the early stages, and usually shows a shadow before there are physical signs of frank consolidation. In cases infected with pneumococcus Type IV agglutinins appear during the second week after the onset. Prophylaxis, it is said, consists in avoiding operation, when possible, on a patient with inflammation of the respiratory tract, in care in the anaesthetic, in protection against chills, and in anticipating pulmonary congestion by digitalis four-hourly for thirty-six hours before the operation.

SEROTHERAPY OF SPIROCHAETOSIS ICTERO-HAEMORRHAGICA.

WHEN originally introduced the immunizing serum for icterohaemorrhagic spirochaetosis was injected hypodermically, but since May, 1916, Inada, Ido, Heki, Ito, and Wani¹ have given it intravenously, and have found this method much more potent. Immune bodies could be demonstrated as complete in the patient's blood five minutes after intravenous injection of 0.5 c.cm. of serum per kilo of the body weight, whereas after hypodermic injection the immune bodies could not be detected until after an interval of eight hours, and were then not completely absorbed. As a rule 60 c.cm. of serum from an immunized horse were given intravenously, irrespectively of the degree of illness; sometimes the whole amount was injected in a single day, sometimes 40 c.cm. on one day and 20 c.cm. the next, or sometimes 20 c.cm. for three successive days. It has not yet been settled which plan is the best. In mild cases a total of 20 to 40 c.cm. is sufficient. The best results follow early injection, and from consideration of the infectivity of the patient's blood, the distribution of spirochaetes in the body, and clinical results it appears that intravenous injection is effective up to the fifth day of the disease. The serum is spirochaetolytic and spirochaeticidal; in two cases its injection gave rise to rigors and a rise of temperature, a serum rash occurred in 3 out of 41 cases treated, but no anaphylactic symptoms were seen. Out of the 41 patients treated, 12, or 29 per cent., died, but after eliminating 3 cases the mortality worked out at 23.7 per cent., or considerably lower than cases not treated with serum. The mortality of patients treated by subcutaneous injection was lower—17 per cent.—but this is correlated with their comparative youth. The serum shortens the duration of jaundice, and it is probable, though not proved, that if given in a pre-icteric stage it may prevent the onset of jaundice. The haemorrhagic tendency is somewhat lessened, particularly from mucous surfaces, and the incidence of suppurative complications greatly reduced. But the fever is not influenced, and the percentage of after-fever is somewhat higher, probably because more patients severely ill recover. From examination of 8 fatal cases Kaneko and Okuda² find that the spirochaetes are markedly degenerated and fewer than in cases not treated by serum, and that their disappearance from the organs and tissues is not so well marked after subcutaneous as after intravenous injection, though the manner of their disappearance is the same.

SACCHARIN.

OWING to the very widespread use of saccharin or allied synthetic substances for sweetening beverages in place of sugar, which is now unobtainable in restaurants and tea-shops, many inquiries have reached us as to whether these coal-tar derivatives, taken continuously though in very small quantities, have any injurious effect. Some quite unfounded statements have been made to the effect that saccharin disturbs the digestion, injures the kidneys, or is even responsible for gastric carcinoma. These appear to have been evolved from *a priori* reasoning when they were not the product of the uncontrolled imagination pure and simple. There is no evidence that saccharin or its allies has any effect whatever on the economy, even when it is used in quantities larger than are required to sweeten foods and beverages to suit ordinary tastes. And this in spite of the fact that saccharin has been in use for more than a quarter of a century. The mere fact that it is an artificial substance remotely derived from coal-tar does not necessarily render it poisonous, as some seem to suspect. At the same time, it is of course valueless as a food in the sense in which sugar is a food, and, even as a flavour, is to most tastes inferior to the natural substance.

¹ A. O. Whipple, *Surgery, Gynecology, and Obstetrics*, 1918, xxvi, 29-47.

² Compare BRITISH MEDICAL JOURNAL, January 12th, 1918, p. 57.

¹ R. Inada, Y. Ido, R. Iloki, H. Ito, and H. Wani, *Journ. Exper. Med.*, 1918, xxvii, 285-305.

² R. Kaneko and K. Okuda, *ibid.*, 1918, xxvii, 305-303.

Glusidum, benzosulphinide, or saccharin, whose empirical formula is $C_7H_5NSO_3$, is an imide prepared from the coal-tar product toluene. When chemically pure it is some 500 times sweeter than sugar, but commercial saccharin is neither a pure nor a uniform product, and often contains less than 50 per cent. of actual glusidum. Besides being a sweetening agent it has antiseptic properties, but these are negligible. In the United States the use of both saccharin and its sodium salt (which is more soluble but less sweet) is prohibited in food or beverages by the Food and Drugs Act. It may be noted that "saxin" is a proprietary preparation said to be considerably sweeter than saccharin, but allied to it in chemical constitution.

FEMININE EQUINISM.

M. QUÉNU, one of the most eminent of French orthopaedic surgeons, has been making investigations, with the help of Dr. Ménard, into the effect of the high-heeled shoe or boot on standing and walking. As M. Kermisson observed in the discussion at the Académie de Médecine, the subject has been forced on male attention recently by the very short skirts that women have taken to wearing. M. Quénu says that the three reasons which induce women to wear the very high heel are that it makes the foot look shorter, that it accentuates the curve of the back, and that it increases the standing height. He admits that the foot looks shorter, because the eye judges its length from the distance between the tip of the toe and the heel of the boot. In one instance, in which the natural length of the foot was 23.5 cm., the distance between the toe and the high heel was only 17.5 cm.; the heel in this case was 9 cm. ($3\frac{1}{2}$ in.) high. The gain in height was only 5 cm. (2 in.). Quénu will not admit any advantage in appearance in throwing the abdomen out and the shoulders back; it entails an ugly hollow in the back and an ungainly balance and gait in walking. Quénu and Ménard regard the arch of the foot as resting on two pillars, the heel behind and the broad anterior end of the metatarsal bone of the great toe in front; they look on the other metatarsals as flying buttresses. In an experiment on a man they found that with the foot bare 70 per cent. of the weight was carried by the posterior pillar, 30 per cent. by the anterior, and that the centre of gravity of the body passed through the external malleolus, or slightly in front of it. When a wedge 5 cm. high was placed under the heel the centre of gravity was thrown 1.5 cm. in front of the heel; the proportion of the weight carried by the anterior pillar was increased to 44 per cent. and that carried by the posterior pillar diminished to 56. In another subject, a woman, with the bare foot the distribution of the weight was the same—30 per cent. in front, and 70 per cent. at the heel; but when a wedge was put under the heel, raising it 6 cm., the amount of weight thrown on the two pillars, front and back, was exactly equal. The centre of gravity was thrown far forward, in fact almost to the centre of the total length of the foot as so raised. This extreme alteration in the distribution of the weight on the foot is corrected in a high-heeled boot by putting the heel far forward. In one young woman, whose bare foot was 19 cm. long, the length was reduced to 15 cm., measured from the artificial heel. The centre of gravity passed much less far in front of the heel and the distribution of the weight became normal—namely, 30 per cent. on the anterior pillar and 70 per cent. on the posterior. In another young woman, in whom the length of foot when bare was 23.9 cm., the wearing of a boot with a heel 9 cm. high reduced it to 19.5 cm. Further, the breadth of the heel in contact with the ground instead of being 5.3 cm. wide was only 2 cm. wide. Quénu and Ménard calculated the total area of contact between the foot and the ground in this subject when standing on one foot: with the bare foot it was 105 sq. cm., with the 9 cm. heels it was 50 sq. cm. This diminution was due to bringing forward the heel, so that the normal distribution of the

weight between the posterior and anterior pillars was obtained by a very great diminution in the surface of contact. This is what they call, ungallantly, equinism, the horse foot, or hoof foot. So far the arch of the foot has been considered as though it were a single bone; when its actual anatomical structure is considered, it is seen that with a high heel the axis of the calcaneum instead of passing upwards passes downwards, the astragalus, which is nearly horizontal, becomes oblique, and the weight is transmitted through it to the scaphoid. In order to maintain the balance the knee is slightly flexed, and the upper part of the trunk is thrown backwards, the flexion taking place at the second or third lumbar articulation. With very high heels the gait is stiff and each pace is short and hurried, the high heel and the toe coming down to the ground practically at the same moment. Eventually the Academy passed a resolution declaring that the fashion of very high heels was injurious and absurd.

THE PRESIDENCY OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

THE President of the Royal College of Physicians of London is elected annually on the Monday following Palm Sunday. It has long been the custom to re-elect the president for several years, and Sir Frederick Taylor had held office for three years, the term for which it was held by Sir Russell Reynolds and Sir Samuel Wilks. He had intimated his wish, on the ground of health, not to be re-elected, and we regret to learn that he was not able to be present at the meeting last Monday. Dr. Norman Moore was elected president in his place and duly inducted by the senior censor, Dr. Samuel West, who had been in the chair. The new president, who is a graduate of Cambridge in arts and medicine, and consulting physician, St. Bartholomew's Hospital, London, became a Fellow of the College in 1877 and has always shown the deepest interest in its work and welfare. He was Bradshaw lecturer in 1889 and Harveian orator in 1901; he gave the FitzPatrick lectures in 1905 and the Lumleian lectures in 1909. He was censor in 1904-5 and 1908, and has been Harveian librarian since 1910. He has been representative of the College upon the General Medical Council since 1901.

ANATOMICAL NOMENCLATURE.

THE Anatomical Society of Great Britain and Ireland, at a meeting on March 1st at King's College, London, received and unanimously adopted a report by its Committee on Nomenclature. It resolved, without a dissentient vote, that the following paragraph of the report should be circulated among the several corporations and other bodies interested in the progress of medical education: "The Committee, after consideration of the matter, unanimously reports that it sees no reason for departing from the use of the old nomenclature as the recognized medium of description for employment in anatomical textbooks and departments, or by medical men in general; on the other hand, it thinks that there are very good reasons to be urged against the adoption of any other nomenclature for this purpose."

A MINISTRY OF HEALTH.

At a conference of delegates from the principal Insurance Committees and Approved Societies on March 22nd at the Central Hall, Westminster, Mr. P. Rockliff, President of the Faculty of Insurance, etc., anticipated that the Government bill for a Ministry of Health, of which Dr. Addison is in charge, would be found, when laid upon the table of the House of Commons, to go far to provide a separate ministry, with National Insurance as an integral part, and including the medical side of the Poor Law. Lord Rhondda assured the meeting that the Prime Minister was deeply interested in the proposal, and quoted Dr. Addison to the effect that his negotiations were

virtually completed, and that the bill would probably be introduced soon after Easter. Everybody, said Lord Rhondda, was agreed that, the difficulties having been surmounted, the bill should be introduced as quickly as possible. In the discussion which followed Major Waldorf Astor, Sir Robert Morant, and Dr. Alfred Cox took part. The general opinion was in favour of the bill so far as its terms had been revealed. The allied topic of reconstruction and the Poor Law was discussed by Sir Donald Maclean, chairman of the Local Government Board Committee which recently reported, and by Lord George Hamilton, a member of the same Committee. The indications at the present time would suggest that the Minister of Reconstruction has found a sufficient basis of agreement between the main parties affected to warrant the introduction of a Government bill for England and Wales, to amalgamate the Insurance Commission with the whole of the Local Government Board, leaving the non-medical functions of the latter department to be shed at a later date. It is not our desire "to pry into the secrets of the State," but this much seems to be common property.

Medical Notes in Parliament.

Tuberculous Soldiers.—In answer to Major Davies Sir A. Griffith-Boscawen said that colonies for tuberculous discharged soldiers were being established at various places in England, Scotland, and Wales, and arrangements were well in hand in connexion with colonies in Dorset (in which case application forms for admission had already been sent out), Cambridgeshire, Cheshire, and North Wales. The occupations in which training would be provided number about twelve, and included market gardening, pig keeping, poultry keeping, bee keeping, fruit culture, horticulture, forestry and rough carpentry, and smith work. Further proposals were under consideration for the establishment of colonies in Edinburgh, Northumberland, Durham, Norfolk, Suffolk, Worcestershire, and South Wales. As the need arose in other areas similar schemes would be considered. In reply to further questions, Sir A. Griffith-Boscawen said that the Ministry of Pensions had contributed in some cases a considerable sum towards the establishment of these farm colonies.

Training Centres for Discharged Soldiers and Sailors.—In reply to Sir W. Havelock-Allan, who called attention to a resolution of criticism passed by the Northern Counties Joint Disablement Committee, Sir A. Griffith-Boscawen said that in providing facilities for training disabled soldiers it was proper, as the need would probably exist for a few years only, to make use of existing institutions, and to arrange when necessary for their extension. If adequate provision could not be arranged otherwise, the creation of additional centres would be considered on their merits.

Poor Law Infirmaries.—In answer to Mr. Needham, Mr. Hayes Fisher said that every board of guardians either had at least one institution wherein the sick poor were medically treated, or had a settled arrangement for their treatment in an institution belonging to another board. There are ninety-five Poor Law infirmaries which had ordinarily one or more resident officers.

Glass for Eye Protection.—Sir J. T. Rees asked whether Mr. Charles Higgins, F.R.C.S., had by experiment established the fact that triplex glass, properly ground and treated, was a valuable protection to the eye from projectiles, splinters, stones, and such substances as were scattered broadcast by shell bursts, and did not itself splinter. Mr. Macpherson replied that some two years ago the question of substituting triplex glass for ordinary glass in spectacles for soldiers was considered, but it was decided not to adopt it in view of the expense involved, and of certain optical objections and difficulties in producing the enormous quantities of lenses required. Trials had also been made of visors fitted with these glasses, but they had not been recommended for adoption.

ON August 13th, 1917, the Cuban Junta Nacional de Sanidad passed a resolution in favour of legalizing cremation in all the cemeteries of the Republic, and the proposal has now received the sanction of Dr. Mendez Capote, Health Secretary.

M. J. GODART, until recently Under Secretary of State for Medical Services in the French War Office, has become the president of a French National Cancer League for the purpose of giving information to the public as to what is known with regard to the etiology of cancer and prosecuting further inquiries and research.

THE WAR.

LESIONS OF PERIPHERAL NERVES RESULTING FROM WAR INJURIES: PATHOLOGY AND TREATMENT.

A MEETING was held at the Alder Hey Orthopaedic Hospital on December 8th, 1917, to discuss this subject. The meeting was opened by Sir ROBERT JONES.

PATHOLOGY OF PERIPHERAL NERVE LESIONS.

Captain SYDNEY M. CONE gave a demonstration of the surgical pathology of peripheral nerve lesions, illustrated by lantern slides. The technique used was chiefly that described by him in the BRITISH MEDICAL JOURNAL, November 10th, 1917. In examining material removed during operations he had cut a very large number of sections from the central and distal ends and from surrounding tissue. Nerve fibres were demonstrated in the proximal end in 100 per cent., in the distal end in 95 per cent., between the two ends in 78 per cent., and in the surrounding adhesions in 80 per cent. In his view the hard tissue about the injured nerves and in the bulbous ends consisted of young nerves more than of fibrous tissue. In several cases he had found young nerves surrounding foreign materials, such as cloth; he had also found nerves growing in the meshes of a sheath of fascia lata which had been wrapped round a nerve junction.

THE DIAGNOSIS AND PROGNOSIS OF NERVE LESIONS.

Professor R. KENNEDY, after referring to the difficulty of diagnosis as to the exact nature of a nerve lesion from the clinical signs, emphasized the importance of obtaining an accurate history from the patient himself. He expressed the opinion that the determination of the nature of the lesion was more important from the point of view of prognosis than from that of treatment, for whether a nerve was anatomically divided or functionally interrupted by compression, the treatment in both cases was operative, although the possibility of doing good by the operation might be greater in the one than in the other. He quoted an interesting case of an unusual lesion which could scarcely have been diagnosed except by operation.

The patient presented a healed wound crossing the arm more or less transversely at the level of the insertion of the pectoralis major and extending over the anterior and inner aspects of the arm. The clinical diagnosis had been total paralysis of the ulnar nerve and partial paralysis of the median. At the operation what was taken to be the ulnar was readily exposed, and it was seen to be united by an extensive scar. The median, however, could not be found so easily, and it was soon apparent that what appeared to be the ulnar was in reality a composite nerve composed of the proximal end of the ulnar and the distal end of the median, while the proximal end of the median was found higher up ending in a large bulbous neuroma. At a lower level in the arm the distal end of the ulnar was found. It was, therefore, through the proximal end of the ulnar that the partial median function was being carried on.

Professor Kennedy called attention to certain circumstances which might have a considerable influence upon prognosis after operation: the existence, for example, of contractures in tendons and muscles and the amount of handling which the nature of the injury might have necessitated at the time of operation. The time which elapsed between injury and operation had an important bearing on prognosis. Investigation of this point had led him to take the view that if operation were performed at any time up to the third month from the date of the nerve section, recovery of movement would, everything being favourable, commence in about three months or a little more; but should five or six months pass before any operation was undertaken, then seven or eight months would probably elapse before there was any sign of recovery of motion. As the time between injury and operation increased, so the date of commencing recovery was advanced, so that when about a year or eighteen months had elapsed no motor recovery was likely to be shown for well over a year, or even two years. In his experience voluntary function was restored soon after contractions were obtainable to faradic stimulation. Nerve injuries met with in this war caused by lacerated wounds which had been infected and had healed after a considerable time, were found to give

results inferior to those of operations for nerve injuries caused by cuts with glass or knives which had not been seriously infected, for such nerve injuries as the latter were dealt with earlier and with less handling. Some years ago he had followed up and published a series of cases he had dealt with up to that date. He classified the results into three groups—as complete success, partial success, and failure. By complete success he meant recovery of sensation and motion with no interference by contractures sufficient to prevent a practically normal function of the limb. By failure he meant cases where no useful result had been attained; and by partial success cases where there had been useful recovery. Of 21 cases where the nerve had been completely severed, there were 10 complete successes, 7 partial successes, and 4 failures. In 14 cases where the nerve had been merely compressed 7 were complete successes and 7 partial successes.

OPERATIVE TREATMENT OF PERIPHERAL NERVE LESIONS.

Sir HAROLD STILES pointed out the great importance of a thoroughly practical knowledge of anatomy. He drew attention to many important points in the operative technique. Speaking of the disadvantages of the tourniquet, he said that the vessels often furnished a good guide to the nerve and its branches, whilst the tendency to oozing after the removal of the tourniquet made it necessary to spend much time over haemostasis. The necessity for using suitable instruments, for an adequately long incision for exposing a nerve above and below the lesion in the first instance, and for clean decisive cutting in place of scratching with the point of the knife, were insisted upon. He deprecated the protection of the wound from the adjacent skin, by clamping gauze to its cut edges, as unnecessarily encumbering the field of operation.

Treatment of the Nerve Lesion.

In dealing with the nerve lesion itself, attention was directed to the following points: if the lesion were complete, the bulbous or cicatricial extremities should be amputated with a very sharp knife, the nerve being meanwhile supported, and enough should be removed to expose the nerve bundles throughout the entire face of both stumps. If the nerve had not been completely divided, all cicatricial tissue should be removed from the sheath, after which the nerve should be carefully palpated to ascertain its degree of induration, and whether or not there were any cicatricial or gliomatous nodules in its substance. Next, the degree of excitability of the nerve to the faradic current should be ascertained, and while this was being done the limb should be carefully exposed distal to the lesion; the disinfection of the skin should, therefore, be continued down to its extremity.

If the nerve had been completely divided, the cicatricial or neuromatous stumps should not be amputated until all was ready for suture. If on stimulating, the thickened or bulbous nerve it was found that the muscular response was fairly good, it was often advisable to incise the involved portion longitudinally in one or two places. If, on the other hand, the faradic response was feeble, an excision should be done, and enough removed to expose nerve fibres free from all scar or neuromatous tissue. In partial lesions of nerves no hard and fast rules could be laid down; each case must be judged on its merits. If in doubt excision should be performed provided that the operator was satisfied that the two stumps could be brought into apposition without tension after the whole of the damaged segment had been removed.

In suturing a nerve the finest linen thread was used. After suture a nerve should not be ensheathed either with a vein, fascia lata, or Cargile membrane, as these materials only served to promote the formation of cicatricial tissue. The best bed for the nerve was one consisting of fatty cellular tissue or healthy muscle.

Date of Operation.

Increased experience had convinced him that often the delay before operating was too long. Delay was justified if there were definite evidence that improvement was taking place; this was more likely to happen if the nerve had been contused as a result of a fracture, or if the symptoms were due to the pressure of callus. In such cases the improvement was progressive, and often ended in complete recovery. In cases, however, where the nerve

had been directly injured by a missile, it was a mistake to wait, although the lesion might be only partial. Many of these partial lesions were attended with severe pain, with aggravated trophic disturbances, and cicatricial or reflex contractures. In such cases valuable time was wasted in waiting for a recovery which in the end was only very partial. If the wound had been healed for a few weeks, there was little fear of trouble arising from the lighting up of latent mischief. The operation could do no harm; the wound was healed in a fortnight, and the exploration enabled the surgeon to ascertain the exact nature of the lesion; the pain, the trophic changes, the reflex spasms, and the contractures often rapidly disappeared. In short, the operation would not only expedite the recovery, but at the same time render it more nearly complete.

The rest of the paper was devoted to injuries of individual nerves, and many important points in their anatomy and the technique of the operation were described.

INDICATIONS FOR OPERATION.

Captain T. P. McMURRAY spoke of his experience of over 300 cases. He had been led to make certain deductions regarding the indications for operation. The absence of faradic response several months after the injury was held to be a definite indication that there was serious impairment of function of a nerve following an injury in its neighbourhood. An exploratory operation, which in competent hands was entirely free from danger, should then be performed, and even if the nerve was merely freed from scar, marked improvement often followed. In his view a month should elapse between the healing of the wound and the operation.

Method of Operation.

Captain McMurray said that his operative technique approximated very closely to that of Sir Harold Stiles. The suture of nerves which had had to be approximated by flexion of joints led to the very interesting question as to the mode of subsequent lengthening which occurred when the limb was straightened. The slight amount of possible lengthening due to the slightly wavy position of the normal nerve had been taken up, and anatomists said that nerve tissue was quite unstretchable when weights were applied even for lengthy periods. It would seem, therefore, that the possible site for the stretching of a nerve was the line of suture, and that the elongation took place in the stretching out of the scar tissue between the two ends. Two facts, however, proved that this supposition was not true—first, the fact that these nerves recovered function even after having been let down from a position of extreme relaxation; and, secondly, a fact which he had noticed personally in six cases in which he had exposed the nerve for inspection several months after suture in flexion. In all these cases a narrow ring indicating where the suture had taken place was seen, and in no case was there an elongated scar which might have been due to the supposed stretching. All workers had found that the chances of recovery of a nerve after suture varied with the particular nerve divided. The best nerve of the upper limb was undoubtedly the musculo-spiral, while the median and ulnar nerves recovered with much less certainty, and their relative recovery was much slower. The reason assigned for this by many observers was the greater proportion of motor to sensory fibres in the musculo-spiral as compared with the median and ulnar nerves.

Blood Supply of Nerves.

In this connexion Captain McMurray expressed the opinion that the relation of the blood supply to the recovery of the nerves was a point of considerable importance. In regard to the blood channels of a nerve very little was known. When a large nerve such as the internal popliteal was found divided and sections were removed from each end down to normal healthy nerve tissue, it was found on arriving at this point that there was a central artery pumping blood from each end, and the deduction seemed to be that from the accompanying artery of the nerve which lay in its sheath, and from small blood vessels in the neighbourhood, tiny branches passed into the nerve between the fibres to a central vessel which coursed along the whole nerve and supplied it in its entirety. This artery he had demonstrated in the internal popliteal, external popliteal, and musculo-spiral nerves, but never in the median or ulnar, and it would seem that although

the blood system in these two nerves was similar to that in the other three, it was much smaller and therefore less likely to nourish young growing nerve tissue.

Captain McMurray preferred chromic catgut for suture material. He had found that after six months the line of suture made with chromic gut showed no sign of a foreign body and no roughness.

Injury without Division.

With regard to cases in which the nerve was injured and not divided, the question as to whether the site of injury should be excised or not arose. In his experience, if a hard fibrous mass were present, functional recovery would not be obtained by simple freeing of the nerve. If, on the other hand, as so often happened, the bulbous enlargement was of the soft fibrous type, freeing the nerve and longitudinally splitting its sheath would be followed by restoration of function.

ACCESSORY AND SPECIAL TREATMENT IN RELATION TO PERIPHERAL NERVE LESIONS.

Captain W. ROWLEY BRISTOW began by saying that no kind of after-treatment could make up for operative imperfections. His belief was that neither the time taken for regeneration of the nerve fibres, nor the completeness of the progress, could be affected to any appreciable extent, and questioned the statement of Tinel that the regeneration of a nerve appeared to be hastened by the simple passing of the electric current. The value of accessory treatment was to prepare the parts against the time when regeneration would take place, and the nerve reacquire its power of conduction.

Accessory treatment was (1) postural, and (2) treatment directed towards assisting nutrition. The former consisted in efficient splintage so as to secure the relaxed position for paralysed muscles. The second embraced heat, massage, electrical treatment, gymnasium and workshop.

Heat must be the preliminary to either massage or electrical stimulation, as muscle contracted better when the part was warm. Moist heat was better than dry before electrical treatment was used, because the moisture lessened the resistance of the skin to the current. Apart from the matter of moisture, no one form of heat was better than any other. In irritative nerve lesions heat usually increased the pain, and was contraindicated.

Massage was useful mainly to increase nutrition in the paralysed part, but it was also of great value if oedema was present. In such cases massage should precede electrical stimulation of the muscles, because, if there were much oedema, the resistance to the passage of the current was so great as to prevent penetration. This point must also be remembered in testing electrical reactions for diagnostic purposes.

The electrical treatment for the paralysed muscles consisted in stimulation with the interrupted galvanic current, this being the only form of electrical stimulus which would promote contraction in the presence of a lesion of a nerve. He did not consider that there was any value in electricity except as a stimulus. In his practice each muscle was made to contract some six or eight times, the treatment being carried out daily. In the early stages it was better to do too little than too much, as fatigue was easily induced. In cases in which there was no oedema, massage could be dispensed with. With return of faradic excitability both currents were employed; the muscle did not regenerate all at once, and if only the faradic current were used some fibres only would be exercised. With full return of faradic excitability the galvanic stimulation was given up, because the graduated contraction method of employing the faradic current simulated physiological contraction more closely and was to be preferred for this reason. The relative time for recovery of faradic response and voluntary power varied. In his experience faradic response was usually the first to recover, but this was not constant. It was only a question of skin resistance, for in all cases in which the exposed nerve was stimulated at operation, if the lesion were incomplete or if regeneration were well advanced, faradic response occurred before any voluntary power could be obtained.

Re-education was a most important part of after-treatment. He endeavoured to initiate and encourage voluntary movement from the earliest stages. The masseuse

spent some time immediately following the electrical stimulation in trying to induce the patient to reproduce voluntarily the action which she had provoked electrically. When a weak and newly recovered muscle was being asked to do voluntary work it should be put into the most advantageous position, and not asked to overcome the force of gravity in addition to moving the part. The value of the gymnasium and of the curative workshop lay in the general effect upon the patient rather than in their local effect upon the injured part. Great harm might be done to recovering muscles by overwork. In hospitals with several departments for after-treatment there was a risk of patients getting too much rather than too little in the way of physiotherapy.

In *causalgia* none of the remedial measures were of any value, and the same might be said for the less severe irritative lesions. Nerves involved in scar tissue, and tender from this cause, were not relieved either by diathermy or ionization.

STATISTICS.

Captain C. B. ALEXANDER gave some statistics regarding cases treated at the Alder Hey Military Orthopaedic Hospital between January, 1915, and December, 1917. During this period 876 cases had been treated—644 were complete lesions and 232 partial.

Relative Frequency of Involvement of Individual Nerves.

Ulnar...	...	265 or approximately	30 per cent.
Median...	...	179	20 "
Musculo-spiral...	...	122	15 "
External popliteal...	...	90	10 "
Sciatic...	...	48	6 "
Brachial plexus...	...	36	4 "
Internal popliteal...	...	26	3 "
Radial...	...	23	25 "
Posterior interosseous...	...	22	25 "
Anterior tibial...	...	18	2 "
Posterior tibial...	...	17	2 "
Circumflex...	...	11	1 "
Musculo-cutaneous...	...	12	1 "
Anterior crural...	...	7	1 "

Of the 36 cases of injury to the brachial plexus the whole plexus was involved in 11, and of the remainder the outer and posterior cords were injured more frequently than the inner—the proportion of 4 to 1. Of the 265 cases of injury to the ulnar the median was also involved in 58, the musculo-spiral in 8, and posterior interosseous in 2. The site of injury to the ulnar nerve was in forearm and wrist 44 per cent., in the upper arm 31 per cent., and about the elbow 24 per cent. Of the 179 cases of median nerve injury 58 were associated with lesions of the ulnar, 7 with musculo-spiral, and 2 with the musculo-cutaneous. The musculo-spiral nerve came third on the list with 122 cases. In 45.7 per cent. the nerve was damaged in the lower third of the arm, in 31.1 per cent. in the middle third, and in 9.8 per cent. in the upper third; 59 per cent. of all injuries of the musculo-spiral were associated with damage to the humerus. Of the large nerves of the upper limb, the musculo-spiral was least frequently associated with lesions of other nerves and most frequently with fracture. This led to the conclusion that the fracture and not the projectile was, in the majority of cases, responsible for the injury.

In the lower limb the trunk of the great sciatic nerve was involved 48 times, and of this number 25 were lesions of both its constituent parts. In 18 the external half only was concerned, and in 5 the internal half. Of the branches of the great sciatic, the external popliteal was involved in 90 cases and the internal in 26. The exposed position of the external popliteal, as it winds round the fibula, no doubt helped to account for the high relative frequency of its injury, but in wounds of the upper part of the thigh it was difficult to explain why the external half of the sciatic was so much more often damaged than the internal half. Makins had written:

The most striking observation with regard to injuries of the great sciatic nerve was the comparatively frequent escape of the popliteal element and the severe lesion of the peroneal. This was so pronounced as to amount to as high a proportion of peroneal symptoms as 90 per cent., and often when the whole nerve was implicated the popliteal signs were of the irritative (or partial) and the peroneal of the paralytic type.

During the period under review 474 operations upon peripheral nerves had been performed, of which 298 were sutures and 176 neurolyses.

Captain Alexander pointed out the difficulties of examining and estimating the results of these operations, and indicated the methods adopted by him in following up the cases for as long as possible. He had been able to trace for a sufficiently long period 260 cases, and the results were analysed as follows:

A. Those which were sutured.

B. Those in which neurolysis was performed.

C. Those in which operative interference was not thought necessary, or operation was not performed for some other reason, for example, sepsis, and which received only electrical treatment, corrective splinting and massage.

Class A (sutures), forming 40 per cent. of the total, shows 14 per cent. of complete recoveries over periods varying from six months to two years, partial recoveries 21 per cent., and no change 64 per cent.

Class B (neurolysis), forming 27 per cent. of the total, shows 14 per cent. of complete recoveries, partial recoveries 40 per cent., and no change 46 per cent.

Class C (no operation), forming 32 per cent. of the total, shows 18 per cent. of complete recoveries, partial recoveries 43 per cent., and no change 38 per cent.

By complete recovery was meant complete return of voluntary power; by partial recovery some return of voluntary power, with or without reaction to faradism, and with return of protopathic sensation.

Of the nerves of the upper limb which had been sutured the ulnar showed 13 per cent. partial recoveries and 3 per cent. complete recoveries, the median 23 per cent. partial recoveries and 38 per cent. complete recoveries, and the musculo-spiral 25 per cent. partial recoveries and 16 per cent. complete recoveries.

When neurolysis had been performed the ulnar showed partial recovery in 28 per cent. of cases, the median 31 per cent. partial recoveries and 15 per cent. complete recoveries, and the musculo-spiral 22 per cent. partial and 44 per cent. complete recoveries. In the lower limb the sciatic and its branches showed partial recovery after suture in 28 per cent. of cases and complete recovery in 7 per cent. Of the cases of neurolysis 62 per cent. showed partial recovery and 14 per cent. total recovery. Of the cases which had not been operated upon 44 per cent. showed partial recovery and 5 per cent. total recovery.

(To be continued.)

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Accidentally Killed.

CAPTAIN P. LEVICK, R.A.M.C.

Captain Percy Levick, R.A.M.C., was accidentally killed in France recently, owing to his horse slipping and falling, and throwing him beneath a motor lorry. He was educated at King's College Hospital, and at Cambridge, where he graduated B.A. in 1895, and M.B. and B.C. in 1898. After filling the posts of house-surgeon and of clinical aural assistant at King's College Hospital, he went into practice at Guildford, where he was honorary medical officer of the Royal Surrey County Hospital. He had served as medical examiner of recruits at Guildford prior to taking a temporary commission in the R.A.M.C.

Killed in Action.

Captain StC. Dunn, C.A.M.C.

Died on Service.

LIEUTENANT G. G. C. ADAMS.

Lieutenant George Gordon Crymble Adams, R.A.M.C., was reported as having died on service in the casualty list published on March 25th. He took the diplomas of I. R.C.P. and S.I. in 1917, and joined the army soon after.

DR. A. K. BAXTER.

Dr. Alexander Kidd Baxter died of typhus at Wei-hai-wei on March 14th, aged 50. He was the fifth son of the late David Baxter, of Leith, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1902. After acting as house-surgeon of Tiverton Infirmary, he went out to China as a medical missionary of the United Methodist Mission, and was for long stationed at Chn Chia Chai, Shantung, North China, in charge of the Yung Ping Fu Mission Hospital. For the past year he had been

serving under the War Office as medical officer of the coolie labour camp at Wei-hai-wei.

Wounded.

Captain H. C. Colver, R.A.M.C. (temporary).

Captain W. J. Phillips, M.C., Australian A.M.C.

Captain F. W. White, R.A.M.C. (temporary).

DEATHS OF SONS OF MEDICAL MEN.

Emmett, Cyril William, Flight Sub-Lieutenant R.N., youngest son of Dr. Richard Emmett, of Winton, Portsmouth, killed March 15th, aged 19. He was educated at Repton, entered the Royal Naval Air Service in May, 1917, and went overseas on January 16th last.

Knowling, Francis John Dobrée, M.C., Captain Argyll and Sutherland Highlanders, younger son of Dr. E. M. Knowling, of Tenby, South Wales, killed March 8th, aged 26. He was educated at Cheltenham College, and was an agricultural student when, at the beginning of the war, he enlisted in the Shropshire Light Infantry. He got a commission in the Argyll and Sutherland Highlanders on September 22nd, 1914, became lieutenant on May 7th, 1915, and captain in September, 1915. He went to France in May, 1915, served at Loos, received the Military Cross in June, 1916, was subsequently wounded, and returned to the front last January.

Mnspratt, Keith Knox, M.C., Second Lieutenant Dorsetshire Regiment, attached Royal Flying Corps, youngest son of Dr. Charles D. Mnspratt, of Bournemouth, killed in a flying accident in East Anglia on March 16th, aged 20. He was educated at Sherborne, got his commission in August, 1916, joined the Royal Flying Corps in November, 1916, and gained the Military Cross in September, 1917.

Stephenson, John, Lieutenant Royal Naval Reserve, younger son of the late Dr. Leader H. Stephenson, reported missing August 13th, 1917, now presumed killed on that date by enemy action, aged 34.

Veraguth, Guy Frank, Lieutenant Royal Field Artillery, only son of the late Dr. C. Veraguth, of Cannes, died in the military hospital at Bristol, of pneumonia following malaria, on March 18th, aged 20. He entered the Royal Military Academy, Woolwich, in February, 1916, passed out first in the same year, and joined the R.F.A. in November, 1916. He had been serving with the Salonica Force in the operations on the Strama river.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SUPPLEMENT to the *London Gazette*, published on March 22nd, gave statements of the services for which the decorations announced in the *London Gazette* of November 19th, 1917 (*BRITISH MEDICAL JOURNAL*, November 24th, 1917, p. 702), were conferred. The following officers of the medical services received the awards indicated "for conspicuous gallantry and devotion to duty":

Distinguished Service Order.

Major Sydney Vere Appleyard, A.A.M.C.

He established a forward dressing station immediately in rear of the front line during an attack, and attended continuously to the wounded, frequently going out and dressing cases in the open under heavy shell fire. His dressing station was hit by a shell, and, though he was badly shaken, he continued his work with great determination and devotion to duty. His fearlessness was an inspiration to all, and was the means of saving many lives.

Major William Wallace Stewart Johnston, M.C., A.A.M.C.

While the enemy were shelling very heavily the positions where assaulting troops were assembled he went out into the open with an absolute disregard of personal safety and attended to the wounded where they lay. After the attack was launched he continued to work for several hours under a very heavy enemy barrage until severely wounded. On many previous occasions his fearlessness and devotion to duty while acting as regimental medical officer have been most conspicuous.

Temporary Captain Gordon Wilson Armstrong, R.A.M.C.

He worked in the open under continuous and heavy shell fire, and dressed and evacuated 117 stretcher cases from his aid post in twenty-seven hours. Later on, while the shelling was very severe, he volunteered to go in aid of an officer and an orderly, carrying them to the aid post one after another on his back. Though wounded during the second journey, he refused to leave his post, remaining with his battalion until it was relieved.

Bar to the Military Cross.

Captain William McMeekin Chesney, M.C., R.A.M.C. (S.R.)

When in charge of stretcher-bearers he continually visited the forward aid posts throughout the day, and supervised the evacuation of the wounded under very heavy shell and machine-gun fire. Though wounded he refused to quit his post until he had rendered a valuable report on the evacuation of the wounded. He worked with indefatigable energy and great courage throughout.

Temporary Captain Robert Welton Hogg, M.C., R.A.M.C.

While in charge of the forward bearer post he worked indefatigably for three days, evacuating the wounded from the regimental aid posts in the line, moving about continuously under heavy enemy barrages. It was entirely due to his fine example and untiring energy that over 200 stretcher cases were safely got away from the front during the first six hours of the attack.

Temporary Captain Maurice Bertram Lawrie, M.C., S.A.M.C.

He established a collecting post in an advanced position, and when his post was filled with wounded he continued to dress cases in the open, though fully exposed to shell fire. In order to satisfy himself that all the wounded had been brought in, he personally searched the whole of the brigade front.

Temporary Captain Hubert Francis Wilson, M.C., R.A.M.C.

He established his regimental aid post in a shell hole close to the firing line, and maintained it in spite of heavy shell fire. During an attack he went forward under heavy fire and attended to the wounded who could not be brought in by the stretcher-bearers. His devotion to duty and unceasing energy is deserving of the highest praise.

Military Cross.**Captain Bernard Gordon Beveridge, R.A.M.C.**

He was in charge of a divisional collecting post and relay bearer posts during an action, and organized and carried out the evacuation of the wounded over the open under continuous fire. It was only by his unflinching courage and energy that the work was successfully accomplished.

Captain Vernon Carlisle Brown, A.A.M.C.

When the officer in charge of an advanced post and a stretcher-bearer were wounded he attended to them under a heavy bombardment and assisted in carrying them to a place of safety. He showed great courage and coolness.

Temporary Captain Dimock Stanley Cassidy, R.A.M.C.

When a party of men were gassed in a mine shaft he went down and remained there all night preparing to render first aid. He did not leave his post even when seriously affected by gas.

Captain George Eustace, R.A.M.C.

He was going forward with a party which came under a very heavy barrage. He remained out in the barrage attending to the wounded regardless of danger, and carried one wounded man several hundred yards through the barrage to safety.

Captain Frederick George Harper, R.A.M.C.

He worked incessantly, attending to the wounded under heavy shell fire. He set a magnificent example to all, and undoubtedly saved many lives.

Temporary Captain James Jack, R.A.M.C.

He established forward collecting posts and dressed and removed the wounded with great coolness and disregard of danger during a period of four days and nights. Most of the time he was under heavy shell fire, and set a fine example of courage to his men.

Captain Charles Hallily Kellaway, A.A.M.C.

For twenty-four hours following the attack he worked without a moment's respite, dealing with the wounded of five battalions in addition to his own, and at the same time controlling the work of his stretcher-bearers.

Captain Harold Howard Leeson, R.A.M.C.

He showed the utmost courage and total disregard for personal safety when commanding stretcher-bearer squads. His splendid example under heavy shell fire inspired those working under him.

Captain James Stewart McConnachie, R.A.M.C.

He was in charge of a divisional collecting post during an attack, and organized and carried out the evacuation of the wounded under heavy fire, in the course of which his post was several times hit. He carried on his work during several counter-attacks by the enemy, and set a splendid example of coolness and courage.

Temporary Captain Charles Fellowes MacLachlan, R.A.M.C.

He worked continuously for forty-eight hours under heavy shell fire, attending to the wounded, much of his work being done in the open. His services were of the greatest value, and he set a magnificent example to all.

Temporary Captain Peter Malcolm MacLachlan, R.A.M.C.

During an attack, as soon as the battalion captured its objective, he went to the front line under heavy shell fire to bring back the wounded. He did excellent work under heavy fire throughout the operations, and showed great gallantry and disregard of danger.

Captain Patrick Joseph Francis O'Shea, A.A.M.C.

While in charge of stretcher-bearers he displayed the utmost courage and devotion under heavy shell fire. His fine example was largely responsible for the maintaining of the lines of evacuation from the front line to the head quarters.

Temporary Captain Alexander Waugh Young, R.A.M.C.

He worked untiringly in attending to the wounded, continually going out into the most forward area under heavy machine-gun fire with his men, encouraging and directing them in their work. It was due to him that nearly 200 cases were evacuated from the line.

Quartermaster and honorary Lieutenant Francis Poole, R.A.M.C.

He remained at the advanced collecting station for several days organizing the rationing of the wounded, and daily visited the relay posts and regimental aid posts with supplies of medical comforts and dressings. During heavy shelling he helped to withdraw the wounded, and lives were saved by his action and example. He has continuously done excellent work.

The King of Italy has conferred the decoration of Cavalier of the Order of the Crown of Italy upon acting Lieut.-Colonel E. F. Eliot, R.A.M.C., and temporary Captain R. H. Lucas, M.C., R.A.M.C.

NOTES.**CANADIAN MILITARY LABORATORY.**

A NOTE in the *Bulletin of the Canadian Army Medical Corps* (No. 1, March, 1918) states that steps were taken at the end of last year to improve the organization of Canadian military laboratories, by subdividing the work and making special arrangements for the training of reinforcing personnel. The laboratories have been divided into four classes: Class A (central laboratories), to deal with all kinds of pathological and public health work,

Class B, Hospital laboratories dealing with general clinical pathological work, including Wassermann tests and tissue sections. They will not deal with sewage or water examination, or other strictly public health laboratory work. Class C, Hospital laboratories dealing with such clinical pathological work as analysis and examination of blood, sputum, stomach contents, urine and faeces, throat cultures and other simple culture work. Class D, Hospital laboratories dealing with haematological and urinary examination and analysis.

It has been decided to use No. 1 Canadian General Laboratory at Folkestone for the training of officers in routine pathological work. Officers and other ranks selected to reinforce personnel for laboratory work, after finishing their regular course of training at the C.A.M.C. dépôt, will be sent to the Folkestone laboratory. The officer commanding it has been given a supervising position in regard to the other laboratories. Each laboratory is equipped for its particular work and he will be responsible for its upkeep. He will also make suggestions regarding standardization of methods of collection and dispatch of specimens, methods of tests and analysis, and methods of recording and reporting. One result of the new arrangements will be that it will no longer be necessary to have fully equipped laboratories attached to all the smaller hospitals. Work sent to a particular laboratory which does not fall within its scope will be transferred to another laboratory authorized for such work. Care has been taken that the organization shall not limit the pathologist as regards research, and any special materials he may need for such work will be granted.

VENEREAL DISEASES.**Defence of the Realm Regulation.**

The following new regulation under the Defence of the Realm Act has been issued: No woman who is suffering from venereal disease in a communicable form shall have sexual intercourse with any member of His Majesty's forces or solicit or invite any member of His Majesty's forces to have sexual intercourse with her. If any woman acts in contravention of this regulation she shall be guilty of a summary offence against these regulations. A woman charged with an offence under this regulation shall, if she so requires, be remanded for a period (not less than a week) for the purpose of such medical examination as may be requisite for ascertaining whether she is suffering from such a disease as aforesaid. The defendant shall be informed of her right to be remanded as aforesaid and that she may be examined by her own doctor or by the medical officer of the prison.

MEDICAL ARRANGEMENTS IN THE ITALIAN ARMY.

Dr. Victor G. Heiser, a member of the American Red Cross Commission to Italy, in a paper read before the Philadelphia College of Physicians on January 2nd (*New York Medical Record*, January 19th), said that the Italians had provided approximately 1,000,000 hospital beds for an army of 4,000,000. There were seven principal units: advanced dressing stations; dispensaries, one or two kilometres behind the front; mountain ambulances from two to five kilometres behind the front, and somewhat larger and better equipped stations further back; mobile hospitals of 100 beds, the whole equipment of which could be transported on five motor trucks and three touring cars; field hospitals with 500 beds, used as distributing centres; base hospitals, providing 20,000 to 40,000 beds, several hundred kilometres behind the lines; and reserve hospitals, in various cities. Each army had a number of large quarantine stations provided with steam disinfecting apparatus or sulphur dioxide chambers; every patient before admission to a general hospital and all prisoners were passed through one of these stations. Hospitals were being located increasingly nearer the front and in very unusual places. Thirty or forty feet underground and directly under a point where a battle was raging, it was a novel experience, said Heiser, to see the hospital routine in good operating rooms and wards provided with artificial ventilation and modern equipment. In another place there was a hospital with 30 beds hewn out of the side of a cliff at an elevation of 6,000 feet in the Dolomites. Practically every hospital had one or more x-ray machines, all manufactured in Italy. The hospital train service worked smoothly. Great progress has been made in methods for the re-education of lost functions. Quarantine stations have been established for malarious soldiers invalided from Salonica and Albania, who, it is estimated, already number 100,000. A comparatively small amount of tuberculosis has been met with in the Italian army, but 30,000 tuberculous Italian prisoners have been returned from Austria. No official records of venereal diseases were available, but these scourges are said to have been reduced to almost negligible proportions.

X-RAY ORGANIZATION IN THE UNITED STATES ARMY.

As soon as America entered the war the matter of x-ray facilities and personnel engaged the attention of the Surgeon-General, and steps were taken to provide the necessary men and equipment. A committee on preparedness was appointed by Dr. Cole, president of the American Roentgen Ray Society, and this committee, together with representatives of other Roentgen societies, in consultation with officers of the United

States army, undertook the work of organizing proper instruction, making a canvass of suitable men, assisting in the design of standard apparatus, and securing a suitable manual for army work. A teaching staff was appointed, with the approval and co-operation of the army medical chiefs, to teach practical roentgenology to officers of the army medical reserve corps. This staff (*American Journal of Roentgenology*, vol. iv, No. 11) consists of roentgenologists in nine large cities in various parts of the States, from New York to Los Angeles. Up to the end of 1917 about 200 had been instructed; but it is estimated that between 600 and 800 will be needed, all of whom will be given a course of ten weeks. The hospital schools and clinics have freely given facilities for clinical work in the various cities where instruction is carried on; although the members of the staff of instruction are widely separated geographically, they are kept in touch with each other so as to secure some degree of unity in training. Provision is also made at the New York centre of instruction, Cornell Medical College, for medical officers of the navy; and an effort is being made to standardize roentgenological equipment in all naval hospitals and ships. The committee has also assisted in the development of the portable field outfit previously mentioned.

Scotland.

THE SYMPATHETIC AND PARASYMPATHETIC SYSTEMS.*

The Parasympathetic System.

In continuing his course of Morison Lectures, Dr. J. J. Graham Brown said that, like the sympathetic, the parasympathetic system was influenced by impulses reaching it from higher centres. The anatomical course and functions of the efferents originating in mid-brain, medulla, and sacral cord were described in detail. Throughout both systems there were many beautiful examples of reciprocal innervation, as where parasympathetic fibres running with the third nerve were motor to the sphincter of the iris, and at the same time inhibited the dilator. Fibres passed in the pars intermedia of Wrisberg to the palate and lacrymal glands, and thus tears might flow not only from emotion (sympathetic) but as a local protective mechanism (parasympathetic). The nerve supply to the salivary glands and other parasympathetic neurones from the medulla were also described. Individuals with high parasympathetic tone had rather copious saliva. Anything which stimulated the system would cause salivation. Other exciting causes were local pain and the psychic or sensory appreciation of food; the flow was arrested by paralyses affecting the neurones, by atropine, distaste for food offered, and by strong emotion (sympathetic dominant).

It was characteristic of the parasympathetic system that the medullated nerve ran straight to its destination, and the synapse was with cells of the local plexus. The vagus sent fibres to such plexuses in the heart, arteries, bronchial musculature, oesophagus, stomach, small intestine, pancreas, gall bladder, and bile duct; its action in relation to each of these was described. Fibres from the sacral cord came from the second and third segments, and were motor to the colon, rectum, and bladder, except the trigone (sympathetic). They inhibited the vesical, urethral, and internal anal sphincters, and dilated the vessels of the erectile tissue.

The parasympathetic protected the individual organs from overstrain and influenced the nutrition of the body and the sexual activities. For the eye it was protective against light, eyestrain, and dust. Through the vagus it saved the heart by inhibiting its rate and strength and diminishing excitability, and by its vaso-dilator action lowering blood pressure. Similarly the lungs were guarded against overdistension by the inhibition of inspiration, against foreign substances by coughing, and against noxious gases by bronchial contraction. An example of this last action carried too far was seen in "gassed" cases, and in such the fear of sleep (parasympathetic dominant) and a resulting spasm of dyspnoea were similarly explained. Again, many parasympathetic symptoms were evidenced during violent coughing. In the alimentary canal the parasympathetic was motor to the muscle wall, inhibitor to the sphincters, and also secretory to the stomach. Thus it provided against overdistension, and ridded the intestine of irritating material, while distension of the rectum and bladder was the reflex for defaecation and micturition.

The system subserved the nutrition of the body in three ways—by promoting digestion and assimilation, by removal of excretory products, and by certain general effects on metabolism. The immediate cause of hunger was a contraction of the stomach wall by parasympathetic neurones and the production of saliva and gastric juice; pancreatic juice, bile, and probably intestinal juice were to some extent secreted under its influence. It removed excreta by its tendency to cause emptying of the intestine and bladder. There was an increased carbohydrate tolerance, no alimentary glycosuria being obtained even with 300 grams of glucose, the effects of pilocarpine administration were marked, and the blood showed a tendency to eosinophilia. As the sympathetic was stimulated by adrenalin it was natural to ask if a corresponding hormone existed for the maintenance of parasympathetic tone, and certain homocholenes derived from the choline of the tissues appeared to act in this way. Special adequate stimuli were certain emotions, such as hunger, anxiety, sexual excitement; irritation either local or reflexly from a distance (for example, gastric hyperacidity from appendicular catarrh or gall bladder irritation), and distension of organs.

Parasympathetic hypertonus was seen not only in individuals with an inborn peculiarity of constitution, but whenever the sympathetic was unduly depressed, or the parasympathetic stimulated by drugs or toxins.

Men showed a constitutional hypertonus oftener than women, and these tended to exhibit a masculine type. A typical picture was of an individual, thick-set, stout (unless emaciated from dyspepsia), eyes, hair, and complexion dark, pupils small, palpebral fissure narrow, features strongly marked and coarse, and nose and lips full. The brow was broad, the face often tapering towards the chin; the skin sallow, thick, greasy. Acne was often present, and dermatographia. The palms and soles were often moist, the fingers cold and livid, and there was a tendency to mental depression. Saliva was copious, the palatal reflex might be absent. There were gastric and intestinal symptoms, and sexual hyperexcitability. Sugar tolerance was high. There was a tendency to eosinophilia, and the individual reacted strongly to pilocarpine.

Hypertonus from depression of the sympathetic was seen during sleep, and then contractions of the bronchial, intestinal, and uterine muscle were most likely to occur from the dominance of parasympathetic innervation. It was seen also in Addison's disease and in myxoedema.

Of the drugs which produce hypertonus the muscarine group formed the chief, while pilocarpine was the most important clinically. The lecturer here put forward the view that the sweat glands, like the lacrymal and salivary, have a double innervation—the sympathetic action associated with fear, the parasympathetic with the protection of the body; probably the sweating of fever was an example of this. Physostigmine, like pilocarpine, was useful where there was diminished tone, and was also laxative by stimulating peristalsis. The parasympathetic was stimulated by the bile salts, also by alcohol in small doses, while long-continued excess paralysed the system.

The serious symptoms from hypertonus were due to intestinal toxins, especially seen in ileal stasis; these toxins belonged to the diamines, the best known being histamine (3-iminazoly-ethylamine) formed by bacteria of the typhoid-coli group. Dr. Graham Brown referred to the likeness which had been noted between this condition and anaphylactic shock, and suggested that this latter should be specially guarded against in individuals showing parasympathetic overtone.

Given the constitutional tendency and toxic action many circulatory and alimentary troubles might follow—bradycardia, chilblains, asthma; gastric hyperacidity and pain returning even after gastro-enterostomy; there might be diarrhoea of anxiety, but more usually there was intestinal stasis, or mucous colitis caused by a spasm of the colon, analogous to asthma (in both Charcot-Leyden crystals are found and there is eosinophilia). Treatment should be directed to limiting intestinal putrefaction, to stimulating the sympathetic by thyroid and the iodides as adrenalin was so evanescent, and by camphor for the heart, and to paralysing the parasympathetic by drugs such as belladonna, hyoscyamus, stramonium. Atropine had the most complete effect, but its action in intestinal spasm depended on the cause; if due to hypertonus it reduced, if the tone was low it augmented, the

* Concluded from p. 357

local reflex; hence it might help some forms of constipation, and was useful in diagnosis. Opium and its alkaloids were also used. The phenanthrene group, morphine and codeine, in small doses, stimulated the sympathetic; for example, the stomach wall was relaxed, and that was pyloric spasm. Similarly the isoquinoline group paralysed the parasympathetic. Of this group papaverine was useful; it had no noticeable narcotic effect, and could be given in doses of $\frac{1}{2}$ to 1 grain.

Examples of treatment were given, as asthma by hypodermic adrenalin or by atropine, stramonium, papaverine, and, in chronic cases, the iodides; "gassed cases" by atropine, adrenalin, iodides, and oxygen; and mucous colitis by papaverine, and adrenalin by the bowel. At various points the lecturer gave details of many interesting cases with the treatment applicable, and throughout the course his remarks were finely illustrated by lantern slide and diagram.

Ireland.

PARLIAMENTARY REPRESENTATION OF QUEEN'S UNIVERSITY, BELFAST.

Candidature of Sir William Whitla.

At a meeting of the medical graduates of Queen's University, held in the Medical Institute, Belfast, on March 19th, when Dr. William Donnan, President of the Ulster Medical Society, was in the chair, the following resolution was unanimously adopted:

That the importance of the Medical School of Queen's University, Belfast, and the number of graduates in the Medical Faculty give the Medical School a very strong claim to provide the representative of the University in Parliament, and that at a time like the present, when matters of public health and of medical attendance on the working classes are claiming and are likely to receive a large amount of attention in Parliament, it is most important that the medical profession should be adequately represented in the House of Commons, an end which may most suitably be attained by the sending forward of medical representatives from this and other universities—representatives who will be untrammelled by the ordinary ties of party, and who will consequently be able to give expert and unprejudiced advice on such matters to the benefit alike of the country, of the profession, and of this university.

In moving this resolution, Mr. R. J. Johnstone, F.R.C.S. Eng., said that the medical profession was handicapped by the limited number of medical men, all of them party men, who were members of the House of Commons. A university representative would not be bound by the party caucus and would be able to speak with special knowledge as to the many medical matters that would arise in the future. In seconding the resolution, Dr. R. W. Leslie said that the medical faculty was the largest in the university, the total fees being more than double those of the other faculties combined. He hoped his colleagues on the senate would look upon the proposal to choose a medical representative with sympathy, for the interests of the medical faculty were not antagonistic to those of the other faculties. The question of primary education, for example, was of great importance to the medical profession, and in fact medical interests were those of the community at large. The resolution was supported by Surgeon T. S. Kirk, also a member of the senate, who observed that the university did not receive sufficient financial support from the city.

This resolution having been carried unanimously, Dr. John Campbell proposed that Sir William Whitla should be adopted as the candidate. He referred to Sir William Whitla's long and honourable connexion with the university, which he represented on the General Medical Council, to his world-wide reputation, to his interest in general politics and the local politics of Ulster, to his diligence as a member of the Irish Convention, to his popularity, not only with the Irish, but with the English and Scottish electors, and to his active interest in education in all branches. The most important reason, he said, for adopting Sir William Whitla was that he was in a position to devote his whole time to his parliamentary duties, and was ready even to give up his professorial chair, if necessary. In seconding the resolution, Dr. Gardner Robb observed that health problems would be most pressing in the immediate future. The ideal was to have a representative in the House of Commons who understood the

teaching side, had a knowledge of medical work from the experience of general practice, and a sympathetic understanding of industrial problems. The resolution was supported by Lieut.-Colonel A. B. Mitchell, and passed unanimously. Professor James A. Lindsay then read a memorial asking Sir William Whitla to permit himself to be nominated, and proposed that the signatories to it should be members of a joint committee for the promotion of his election. The proposal was seconded by Dr. F. C. Maun (Dungannon) and unanimously approved.

Our correspondent in Belfast states that the feeling in that city in favour of returning a medical man to represent the Queen's University in Ireland is very strong. The large and flourishing medical school has been for over sixty years the mainstay and backbone first of the old Queen's College from its foundation, and later of the Queen's University. But for the success of the medical faculty it is doubtful whether the university would have come into existence. It is particularly desired that the representative shall be a man of science, preferably a medical man, able to join in the forward movement of educational reform and to appreciate the great medical changes of all kinds that are imminent.

Correspondence.

THROMBOSIS AND EMBOLISM.

SIR,—The very interesting article by Mr. Charters Symonds in your issue of March 23rd, in which he draws attention to the positions of the patient in favouring thrombosis after operation, encourages me to offer, in support of his inference, my own opinion on a like subject; namely, in patients recovering from long illnesses, such especially as typhoid fever. My pupils will remember that for many years I have taught, and incidentally have published, the opinion that in such cases we meet with two kinds of thrombosis: first, that directly due to the septic element of the disease, and this may occur early in its course, as in pneumonia; secondly, that described by Mr. Symonds as occurring during convalescence. This latter kind I have attributed to the recovering strength of the patient, who finds at last he can throw one leg over the other, and even turn to sleep on his side. For many years I have impressed upon nurses and patients the duty, as the strength is restored, of avoiding all positions of pressure on a limb.—I am, etc.,

Cambridge, March 25th.

CLIFFORD ALLBUTT.

PARALYSIS FOLLOWING ARTERIAL INJURIES.

SIR,—It is remarkable that a kind of intermittent claudication of extremities (as described by Charcot and others) should be such a frequent and striking symptom in limbs (usually one or both lower limbs) affected by "thrombo-angiitis obliterans," whereas in cases of paralysis of traumatic vascular origin, such as the ischaemic cases of traumatic "angiotic" paralysis of extremities, recently described in the *BRITISH MEDICAL JOURNAL* (1918, i, p. 199) by Captain Harold Burrows, the symptom in question should be absent, or only present in the clinical background.

Another well-marked difference in the symptomatology of the two groups of cases is the absence in thrombo-angiitis obliterans of the typical anaesthesia or hypoaesthesia of stocking-like or glove-like distribution, which constitutes so noticeable a feature in the traumatic (ischaemic) cases described by Captain Burrows. I believe that after more or less complete recovery in traumatic cases one curious symptom may sometimes be observed—namely, a greater tendency to muscular cramp in the limb that has been injured than in its fellow. This was so in the case of a man, aged 41 years, whose case I described in an article on "Muscular Cramp" (*American Journal of the Medical Sciences*, May, 1894). The patient, in 1889, had apparently had his left common iliac artery obliterated by a traumatism, and was an in-patient, under Sir William Savory, at St. Bartholomew's Hospital, when I was house-surgeon. Cutaneous anaesthesia of "stocking" distribution was well marked, but there was no intermittent claudication, though when the patient was seen three years later there was still considerable impairment

of sensation in the limb. When lying in bed and asleep he was then sometimes awakened by cramp in the left leg. This was only when he went to sleep with his legs drawn up, but, although both legs might be drawn up, the cramp occurred only in the leg that had been injured.—I am, etc.,

London, W., March 16th.

F. PARKES WEBER, M.D.

EUROPEAN v. AMERICAN ETHER.

SIR,—I send you part of an interesting communication on anaesthesia at the front by a well-known American anaesthetist.¹ He voices the difficulty in producing anaesthesia by the open method which I have heard many American *confrères* in this country express. They find that they cannot produce anaesthesia with the ether prepared from methylated spirit, which we use, within a reasonable time and without a good deal of excitement even in patients who have recently had a preliminary dose of morphine and atropine. On the other hand, the late Sir Frederic Hewitt, who was a great advocate of open ether by much the same method as is in use in America, did not, I believe, find any special difficulty, although he used of late years ether produced from methylated spirit. Personally, although I never administer open ether *ab initio*, I have not noticed any difference between British methylated ether and American ether (Squibbs), which is pure ethyl oxide.

Professor Crile, writing on his experiences in an American hospital in Paris before America joined the allies, said that the American anaesthetists found that French soldiers did not take gas and oxygen or ether as well as did patients in the United States. (I presume that in his hospital American ether was used.) He suggested that the difficulty arose because French soldiers were accustomed to take a little alcohol.

These variations in the production of anaesthesia are probably not due to any difference in the method, which is much the same everywhere. They can only be accounted for by the difference (1) in the drug used, (2) in climate, (3) in racial characteristics or mode of life.

I cannot think that European or British methylated ether is so much inferior to the American ether as Lieutenant Guedel believes, and am inclined to attribute his difficulties to the last two factors mentioned. It is impossible to obtain American ether in this country, otherwise it would be of great value if British anaesthetists could administer it and compare results with those of their American *confrères*.—I am, etc.,

Birmingham, March 12th.

W. J. MCCARDIE.

PHARYNGEAL HAEMORRHAGE DUE TO LEECHES.

SIR,—This accident was very common in Napoleon's army when retreating from Syria into Egypt. Larrey (*Mémoires*) describes many cases.—I am, etc.,

March 22nd.

W. P. HERRINGHAM.

Obituary.

R. S. TREVOR, M.B., B.C.CANTAB.,

LECTURER IN PATHOLOGY, ST. GEORGE'S HOSPITAL.

ROBERT SALUSBURY TREVOR, a member of a family much connected with Indian military history, was the son of the late Colonel S. T. Trevor, and was born in India on January 22nd, 1872. Together with his twin brother (now Lieut.-Colonel W. H. Trevor, D.S.O.) he spent two years (1885-7) at Marlborough, and then was at "Wren's" with a view to the Indian Civil Service. This course, however, he abandoned, and subsequently went to Clare College, Cambridge, graduating in the Mathematical Tripos in 1894 and proceeding to the M.A. degree in 1898. In the meantime he had joined the medical school of St. George's Hospital, where his life's work was destined to be done. After taking the M.B., B.C. degrees he became curator of the museum and demonstrator of morbid anatomy. The high character of his work ensured his election as lecturer on pathology in the medical school and pathologist to the

¹First Lieutenant A. E. Guedel, *American Journal of Surgery*, January, 1918.

hospital in 1906, and he thus became entirely responsible for all the routine work entailed by these posts. In addition he was soon appointed pathologist to the Belgrave, Samaritan, General Lying-in, and Grosvenor Hospitals, lecturer on forensic medicine and toxicology in the medical school, and became increasingly in request as an expert in medico-legal work among the coroners of London. He was also for a time warden of the medical school and, from 1911 until his death, dean of the medical school. These multifarious activities may to some extent explain why his literary output was comparatively small, for he had collected much material, especially on the causes of sudden death, such as intracranial aneurysms and the status lymphaticus, and on congenital abnormalities. But the main reason was characteristic of the man—namely, genuine and unobtrusive modesty. Scattered papers on splenic anaemia, the morbid anatomy of the pancreas and other abdominal organs, and on medico-legal subjects, appeared under his name from time to time, but most of them saw the light only because they were conjoint efforts or specially called for, and any suggestion of self-assertion was entirely foreign to his mental attitude. His work was most thorough and methodical, and his wide experience, well enforced by a knowledge of foreign literature, rendered him an authority to whom frequent appeals were made, always met as a matter of course by most unselfish help. His hospital records will long serve as a model to his successors, and to his colleagues in the school and hospital his sad death is an irreparable loss.

Apart from his engrossing professional career, Trevor had other sides: he was a fine singer, a good speaker, was interested in old books, archaeology, and photography, held high rank as a Freemason, and entered fully into the life of the medical school, where he exerted a powerful though unostentatious influence for unity and right living. Charming as a companion, conciliatory as a colleague, and transparently honest, he was firm in what he considered right, and yet it is doubtful if he had any enemies. Of a sensitive nature, though few signs of this were allowed to appear on the surface, he was further handicapped by indifferent health, much aggravated by chronic overwork. Latterly the increased strain due to hospital shortage, and the disturbed nights entailed by his duties as a special constable, no doubt accentuated his long-standing tendency to depression, and thus led to the premature loss of a life characterized by self-sacrifice and devotion to duty.

The funeral took place at Kensal Green Cemetery on March 25th.

We have recently learnt with great regret of the death of Dr. E. J. EDWARDES, who was well known to the profession as an authority on the history of vaccination. He was the sixth son of Mr. Thomas Edwardes, F.R.C.S., of Llansantffraid, Montgomeryshire. His mother was an Englishwoman. He received his medical education at St. Mary's Hospital medical school, at which he held a scholarship in natural science in 1871, and in pathology in 1876; before winning the latter he took the diploma of L.S.A. in 1875; he became L.R.C.S. Edin. in 1887, and graduated M.B. Lond. in 1876. After holding the office of house-surgeon to the Western Ophthalmic Hospital, Marylebone Road, he joined his father for a time, but later settled in practice at Llanfyllin, Montgomeryshire, where his practice covered a very large area, and he held many appointments. After a few years he married and settled in London, taking the M.D. Lond. and the M.R.C.P. in 1882. He was at one time assistant physician to the North-West London Hospital, and physician to the Farringdon and to the St. Pancras Dispensaries. He was a man of many interests, a good linguist, and widely read in many subjects. In 1892 he published a remarkable little book entitled *Vaccination and Small-pox*, and ten years later *A Concise History of Small-pox and Vaccination*. In the same year he contributed an article entitled "A Century of Vaccination" to the Jenner Number of the BRITISH MEDICAL JOURNAL. He assisted Mrs. Garrett Anderson in the foundation of the Imperial Vaccination League, formed to appeal (which it did with much success) to the general public, and especially to those conducting large retail businesses; after Mrs. Anderson's retirement he became its honorary secretary. Among other subjects with which he occupied himself was the preparation of a book on mathematics, but the chief interest of his later

years, after his retirement from practice, was the preparation of a translation of Dante's poems; a translation of Hell was published about two years ago, and those on Purgatory and Paradise were in course of preparation. His health began to fail early in 1917; he became seriously ill in August, and died on December 11th. He is survived by his widow, by a daughter, and by a son who holds a Government appointment in Burma.

DR. BROOKS H. WELLS of New York, professor of gynaecology for many years at the New York Polyclinic Medical School and Hospital, and editor since 1892 of the *American Journal of Obstetrics and Diseases of Women and Children*, died recently at the age of 58.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE degree of Doctor of Medicine has been conferred on Eric A. Pearce-Gould, and the degree of M.A. *honoris causa* upon R. H. Anglin Whitelocke, M.D. Edin.

UNIVERSITY OF CAMBRIDGE.

PARLIAMENTARY REGISTER.

THE Registry of the University desires to make it known to graduates who are not already on the register as members of the senate, including Bachelors (who became full Bachelors in the December of the year in which they were admitted to their degrees), that they are entitled to be placed on the register of parliamentary electors of the university under the provisions of the Franchise Act of 1918. Forms for making the necessary claim will be sent on application to the Registry.

UNIVERSITY OF MANCHESTER.

THE following gentlemen have obtained the Diploma of Public Health: G. M. Coope, Isaac Flack, T. E. Flitcroft, J. E. Lezama, H. E. R. Stephens.

UNIVERSITY OF ABERDEEN.

At the graduation ceremony on March 22nd the following degrees were conferred:

M.D.—F. L. Keith, W. B. Livermore, Major J. Macpherson, A.A.M.C., *W. L. Miller.
M.B., Ch.B.—† J. D. Brown, I. G. Innes, Winifred M. A. Kindness, Mary J. M. MacLaren, A. Ritchie.

* Commended for thesis. † With second class honours.
‡ Passed fourth professional examination with distinction.

UNIVERSITY OF GLASGOW.

RESEARCH FELLOWSHIPS IN MEDICINE AND APPLIED CHEMISTRY.

UNDER the bequest of the late William Brechin Failla, Writer in Glasgow, a Research Fellowship in Medicine, of the annual value of about £200, tenable for three years, has been founded in the university. The Fellowship will be awarded, on the recommendation of the Faculty, by the *Senatus Academicus* to a recent graduate in medicine who has shown capacity for independent inquiry or research. He will devote himself to some branch of work approved by the *Senatus*, and will not engage in professional practice. He may be authorized or required to pursue his inquiry for one year elsewhere than in the University of Glasgow. The Ferguson Trustees have announced their intention of founding a Research Fellowship in Applied Chemistry, also of the annual value of £200, tenable by a Bachelor of Science of the University. He will be expected to carry out his investigations either at the university or at the affiliated Royal Technical College.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AT the meeting of the Royal College of Physicians of London on March 25th, when Dr. Norman Moore, as is noted elsewhere, was elected President, it was resolved, on the recommendation of the Committee of Management, that, inasmuch as the South African College, Capetown, is to become the university of Capetown on or about April 4th, the courses of instruction in chemistry, physics and biology, anatomy and physiology, hitherto recognized by the Conjoint Board in England when given at the South African College, shall be recognized under the constitution of the new university, and that the examination in chemistry, physics, and biology for the degree of bachelor of science of the university of Capetown shall be accepted in lieu of the first professional examination of the Conjoint Board in England in those subjects. The Western University, London, Ontario, was restored to the list of universities recognized by the Examining Board of England. At the same meeting a gift from Mrs. John Abercrombie of a pair of scales, formerly the property of Dr. Edward Jenner, was accepted.

Medical News.

THE Wellcome Historical Medical Museum will be closed for cleaning from April 1st to 30th inclusive.

ANDREW TAYLOR STILL, the founder of "osteopathy," died recently at the age of nearly 90.

AT a meeting of the College of Ambulance, Vere Street, London, on March 23rd, it was decided to place the institution on a permanent basis, for which purpose a considerable sum of money will be needed. Its founder, Sir James Cantlie, expressed the hope that it would be linked with the University of London, and brought into relation with the new Ministry of Health.

A PAPER on the medical aspects of the food problem will be read by Dr. Robert Hutchison at a meeting of the West London Medico-Chirurgical Society, at the West London Hospital, on Friday, April 5th, at 8.30 p.m.

PROFESSOR ARTHUR KEITH will give at the Royal Institution after Easter a course of five lectures on British anthropologists, and Dr. C. S. Myers two lectures on present-day applications of experimental psychology.

AN entrance Salomons Scholarship of £50 at Epsom College will be vacant at the beginning of the summer term. Applications must be received, addressed to the Secretary of the College, 37, Soho Square, W., by April 6th.

THE annual meeting of the Medical Sickness Annuity and Life Assurance Society will be held at the Holborn Restaurant on Friday, May 3rd, at 4 p.m. Nominations for members of the committee must be received in writing at the society's office, 300, High Holborn, W.C., not later than one month before the date of the meeting.

THE regulations of the University of London with regard to the M.D. (State Medicine) have been amended to recognize laboratory experience at a base hygiene laboratory and experience in charge of a base district on lines of communication of a British expeditionary force. Full particulars can be obtained on application to the Academic Registrar.

THE University of Edinburgh has accepted an invitation to attend a conference summoned by the Foreign Secretary and the Minister of Education to consider, with representatives of other universities, the possibility of establishing closer connexion between British universities and those of the allied countries. The conference is to be held on May 9th.

AT the monthly meeting of the Central Midwives Board on March 21st, the chairman, Sir Francis Champneys, referred with deep regret to the death of Mr. Arthur Henry Williams Ayling, L.S.A., who had represented the Society of Apothecaries, and announced that Mr. Charles Sangster, M.R.C.S., L.S.A., had been appointed his successor. Twenty-nine midwives were removed from the roll on their own application. At the meeting on the previous day four women had been struck off the roll on various charges.

THE Prehistoric Society of East Anglia is an energetic body which now draws members from districts far beyond its borders, and not a few among them are members of the medical profession. Its president last year was Dr. A. E. Peake, who does not reside in East Anglia, but his address described some new excavations of Grime's Graves at Weeting, in Norfolk. Like other papers in the *Proceedings*, and like indeed a great part of the matter on prehistory now being published, it is largely concerned with attempts to date, or rather to find epochs for, the objects unearthed.

AT the annual Court of Governors of the Hospital for Epilepsy and Paralysis, Maida Vale, on March 22nd, the observations made by Mr. Hodge, to which we referred last week (pp. 346, 352), and the letter by Professor Elliot Smith in the *Times* of that day, were discussed. It was pointed out that the Home of Recovery at Golders Green was established as a branch of the hospital at the end of May, 1917, to receive men, on the recommendation of the Ministry of Pensions, who had been invalided from the services suffering from what is commonly known as "shell shock." Two resolutions prepared spontaneously from the patients at present in the Home, numbering 95, and signed by all, had, it was reported, been sent to the Committee. The resolutions stated that all having benefited, and in many cases recovered, they desired to express their contentment and satisfaction with remaining in the institution. Past experience in general hospitals had taught them to appreciate separation from other cases, especially from the so-called "cheery man"; they preferred "to risk the air raid results before that of going to another hospital."

Letters, Notes, and Answers.

The telegraphic addresses of the BRITISH MEDICAL ASSOCIATION and JOURNAL are:

1. EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology*, Westrand, London; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Mediscera*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC.

GONORRHOEA COMPLICATED BY SYPHILIS.

DR. JAMES S. ROBERTSON (London, W.) states that during his term of service as house-surgeon in the London Male Lock Hospital he never saw a case of gonorrhoea in any way aggravated by an intravenous injection of novarsenobillon. In many such cases he observed that joint pains vanished after an injection.

DR. C. F. MARSHALL (London, W.) writes: Captain Lumb attributes gonorrhoeal complications, such as epididymitis, prostaticitis, etc., arising during treatment with mercury and arsenobenzol in cases of double infection with syphilis and gonorrhoea, to the action of the mercury rather than the arsenobenzol. The evidence in support of this view is not convincing. In the pre-salvarsan days mercurial treatment was more intense than it is now, when it is subsidiary to arsenical treatment, but gonorrhoeal complications seldom occurred in patients undergoing mercurial treatment for syphilis; on the contrary, the mercury appeared to have a beneficial effect on the gonorrhoea. A more probable explanation would appear to be that the phenomena observed were due to gonococcal invasion of tissues rendered vulnerable by the hyperaemic action (Herxheimer's reaction) produced by the arsenobenzol.

THE OLDEST ENGLISH HOSPITAL.

MR. A. H. COUGHREY (Librarian, St. Bartholomew's Hospital and College, London) writes: It comes as rather a shock to many of us to read in your columns that Angers Hospital is claimed to be the oldest English hospital, presumably on the ground that at the time the hospital was founded England possessed that part of France in which it was situated (by-the-by Henry II did homage to Louis). Doubt is suggested that St. Bartholomew's Hospital was really a hospital. *Liber fundacionis ecclesie Sancti Bartholomei Londoniarum* makes it quite clear that sick people, many of them from distant parts of the country, were received in the hospital, though their cures were attributed to miracles at the shrine of the church. There may be a similar objection to the title of St. Bartholomew's Hospital at Rochester on the ground that it was a lazaret house. This noted Kentish hospital was founded by Bishop Gundulph in 1078, forty-five years before its namesake in London, as a hospital for lepers.

* The building erected by Henry II when he founded the Hôpital Saint Jean at Angers in 1170 is now the Archaeological Museum, the larger part of the collection being displayed in the great hall. Over the entrance to the present hospital, built early in last century, is a tablet recording that the hospital was founded by "Henry II Comte d'Anjou et roi d'Angleterre."

"A MEDICAL SECRETARIAT."

A CORRESPONDENT sends us a curious document which he has received by post, and upon which he invites comment in the JOURNAL. It is in the form of a printed letter head "Confidential," enclosed in an envelope marked "Personal"—for which reasons we suppress the author's name. He begins thus: "Re a Medical Secretariat. In view of the possibility of a State Medical Service after the war, the proposal outlined herein is being promulgated amongst the Temporary Medical Officers of I.M. Services, in the hope that its adoption will considerably benefit the profession generally and to a large extent nullify the necessity for State intervention." Pompous, perhaps, but whetting to the appetite. He proceeds: "Whilst the medical man's inherent dislike of any form of compulsion or 'unionism' is at once acknowledged, it is submitted that it is of the utmost importance to the medical profession (and not less so as regards the national health) that the young doctors, who will be more or less suddenly thrown upon their own resources after 'demobilization,' should be themselves organized in order to effectively adjust the law of supply and demand regarding medical services. It is therefore proposed to inaugurate a medical secretariat with offices in London and to charge an annual subscription of £1 ls. to cover working expenses, with membership open to all registered doctors, dentists, and medical students." Likely openings for young practitioners are to be investigated, and the usual business of a medical agency transacted on behalf of the members. A system of accountancy is also to be introduced "whereby with absolute secrecy and satisfaction

guaranteed, medical men throughout the country would be enabled to have their bookkeeping done for them by the secretariat for an inclusive fee of 5 per cent. on the total amount received on behalf of the member." The scheme, we learn, has been placed before a number of temporary naval surgeons, and the author has been asked to undertake the task of organization, which he is prepared to do if enough support is forthcoming. A form of application for membership is enclosed, and there are three appendices, the first outlining the system of accountancy proposed, the second indicating subsidiary secretarial work which the author is willing to do—such as arranging loans by mortgage and the settlement of business disputes—and the third giving the modest story of the author's career, from which it appears that he is the son of a deceased doctor, that his age is 30, and that he hopes to obtain a "chartered secretary's" diploma next June. Lastly, there is a note that he will shortly place the proposal before the General Medical Council with the idea of obtaining semi-official recognition in view of the national importance of its primary object. In the meantime we gather that this ambitious leaflet is being distributed widespread among temporary surgeons R.N. Stripped of high-sounding phrases, the idea seems to be nothing more than a plan for setting up a medical and dental agency and bookkeeping institution, with side lines in the way of income tax and insurance work and the transaction of business which is usually placed in the hands of a solicitor. All this the originator of the scheme is prepared to take upon his own shoulders, on the strength of eleven years' service in a bank and three years' experience as accountant in the Royal Naval Reserve. Not a word is said about a managing committee, a board of directors, or other controlling body. Without in any way desiring to question the author's good faith, we cannot advise junior members of the profession to rally round this medical secretariat, even though "to give the proposed scheme an unbiased trial would cost you 21s. only."

CULTIVATION OF DRUG PLANTS.

DR. G. F. SYDENHAM of Dulverton, Somerset, writes to express surprise that the British Medical Association has not made a special effort to encourage the cultivation of native drug plants. The stocks in hand of manufacturing chemists are, he says, being used up. The National Herb Industry, Ltd., of Verulam Street, London, he is informed, last year sold £1,000 worth of herbs to chemists, and in January this year had orders for £12,000 worth. He is honorary local secretary for the enterprise, and believes it to be an honest attempt to meet a national necessity. This country, he considers, can supply a large part of the trade demand; some of the plants grow wild, but others will have to be cultivated. His district is, he says, the home of digitalis and male fern, while hyoscyamus grows wild on the north coast of Somerset. Belladonna is, he states, a profitable herb to grow. Further development and organization are, he considers, necessary to provide the drug plants required.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE following subscriptions to the Fund have been received during the week ending March 25th:

	£ s. d.		£ s. d.
Dr. Frank Hinds ...	2 2 0	Messrs. Parke, Davis and Co. ...	100 0 0
Dr. G. A. Sutherland ...	3 3 0	Dr. J. W. Papillon ...	1 1 0
Major John Robert Williams, R.A.M.C.T. ...	1 1 0	Mr. G. H. Knowles ...	1 1 0
		Mr. J. R. Phillips ...	0 10 0

Subscriptions to the Fund should be sent to the Treasurer, Dr. H. A. Des Vœux, at 14, Buckingham Gate, London, S.W.1, and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Limited.

ERRATA.

Treatment of Shock.

In a paragraph, on post-operative complications and treatment, of the paper on gunshot wounds of the abdomen by Captain R. Charles (BRITISH MEDICAL JOURNAL, March 23rd, p. 339, col. 2), the sentence with regard to intravenous injections for shock should have stated that the proportion of gum acacia used was 6 per cent., and not 2, as printed.

Prophylaxis of Pneumococcal Infections.

In the third line from the end of the leading article on prophylaxis of pneumococcal infections (BRITISH MEDICAL JOURNAL, March 23rd, p. 351, col. 2) for "antipneumococcal vaccine" read "antipneumococcal serum."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£ s. d.
Seven lines and under ...	0 6 0
Each additional line ...	0 0 9
Whole single column ...	4 0 0
Whole page ...	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *postes restantes* letters addressed either in initials or numbers.

NOTES FROM A CLINICAL LECTURE ON A CASE OF HUNTINGTON'S CHOREA.

DELIVERED AT ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

BY

PROFESSOR SIR CLIFFORD ALLBUTT, M.D., F.R.S.,
PRESIDENT OF THE BRITISH MEDICAL ASSOCIATION.

GENTLEMEN, I have asked this patient to present himself here this morning in order that you may see a case of a very infrequent disease; I cannot recall more than four such cases, if indeed so many, in my own experience. The title of Huntington's chorea I retain because Huntington—a physician of New York—published, in 1872,¹ the first comprehensive description of the malady. It seems to have had some endemic prevalence in Long Island, New York, as Huntington's father and grandfather and other physicians in the district had observed and distinguished it. The Huntingtons laid much stress on the hereditary incidence. This record fell into neglect until 1884, when Ewald recalled attention to it. Many cases have since been described in both hemispheres, some with necropsy.² The alternative title of Hereditary Chorea I avoid because in many instances it has not been obviously hereditary, and no such condition is present in the case now before you.

At one of our Discharged Soldiers' Employment Committee meetings the last case on the day's list was of a man, X. Y., who had been sent from one hospital to another as a case of "neurasthenia"; and ultimately discharged. I was thinking it not worth while to wait longer for one of this crowd when the door opened in an irresolute way, and an arm was thrust through with a spasmodic jerk; then a leg followed with a like unsteadiness; then, while the right hand twitched at the handle, the corresponding body clinging to the door edged itself round with a random attempt to close it. Then with a stagger the patient lurched forwards to our table with the gait you have seen just now, a tripping staggering gait, hastening and stopping, until he reached the chair. Yet even in the chair you see, as we did, that the man is still in incessant restless motion, like a marionette; now jerking an arm, now the trunk of the body, now shrugging a shoulder, and so on, just as a girl does in St. Vitus's dance. We are told that these movements never cease except in sleep. He is not grimacing, he puts his tongue out fairly steadily, and his speech is unaffected; notwithstanding, the first glimpse of the patient should suffice to stamp his malady on the mind of the observer.

X. Y. lives in a village in this county; and I am much indebted to Dr. Sydney Williams of Meldreth for the trouble he has kindly taken in obtaining careful and complete notes of the case and in arranging for the patient to attend at the hospital this morning.

X. Y., aged 46, was born in our county. He joined the army and served in India for seven years. Then he served in S. Africa three years. His father died at the age of 80; always a healthy man. His mother died at the age of 55; cause unknown. They had three sons, all living, and the two others are in good health; one, aged 51, is an officer's servant, the other, aged 48, an agricultural labourer. There is no history in the family of "fits, St. Vitus's, or insanity." In respect of personal history patient had always enjoyed excellent health, and escaped all infectious diseases—in his own words "he never knew his own strength." He is a life teetotaler, and never had any venereal disease. In India he took part in athletics, and ran the half mile for his regiment. He smokes about half an ounce of tobacco a week.

When on duty one night at the front with a pioneer battalion, as Zeppelins were about, orders were given to man the trenches; and in making for the trench he fell into it—some 6 or 7 ft.; he fell on his right knee, but did not regard the blow seriously till a month later when the involuntary movements began on the right side. Within two months the disorder had attacked the left side also, and soon all his body and limbs were involved in it. There is no apparent mental defect, but the patient says that his "memory has suffered much." He cannot retain his urine as well as he did. There is one point, almost the only one, in Huntington's chorea in which the movements

differ a little from ordinary chorea, namely, that in the earlier stages of the malady at any rate—as other observers of these cases have recorded—certain concerted movements may be performed with normal co-ordination; especially if the patient is tranquil and bent upon some task. Dr. Williams writes:—"I have noticed him in the road collecting dung for his garden, and when carrying the bucket and shovel the choreic movements are practically in abeyance." This occasional co-ordination, I repeat, agrees with records of other observers of this disease. One patient is said to have continued his occupation as a carpenter and to have "driven nails with fair precision." On the other hand, writing was almost impossible. The patient after much effort did succeed in making a sort of signature of his name, but it was scrambling and barely legible. The strength of his muscles seems unimpaired, at any rate as yet, and the tendon jerks were lively.

In short, this case corresponds in all respects with the recognized pattern of the malady, save as regards the absence of heredity. When heredity is apparent the malady has always been present in the preceding generation. There is a chorea described as senile chorea which comes on between the ages of 55 and 80, and is not hereditary. Other maladies affecting elderly persons, disorders of the nervous system, have been indiscriminately called chorea; such as athetosis, paralysis agitans, senile tremor, hysterical rhythmic spasms, and so forth. We can scarcely accept a limitation of the nomenclature by the element of heredity alone; but its absence may suggest a somewhat less gloomy prognosis. The incidence of Huntington's chorea falls rather more upon males, and usually about the age of 40.

Whether Huntington's chorea will prove to be identical with "senile" chorea I cannot say; we know too little of their respective natures and causes, but provisionally they should be regarded as one malady. It is said that both symptoms and morbid anatomy in Huntington's disease and in the "senile" are identical; though it is true that the occasional recovery from the "senile" kind, and perhaps the better preservation in it of the mental faculties, seem inconsistent with a parenchymatous degeneration attacking the neurons primarily, or very early. But these cases of alleged recovery are as yet imperfectly verified. Moreover we must not give the name of chorea to the common tremors and shuffles of elderly people with arterial and other senile degenerations. In these the motor instability is of another order. The descriptions of "senile" cases too often contain other forms of disorder, such as post-hemiplegic spasms, athetosis, shaking palsy, tics, festination, myoclonus, etc. The patient before us is no degenerate. It cannot be too clearly understood that in Huntington's chorea the muscular eccentricities are of the same order indeed as in Sydenham's chorea. By these alone the two kinds cannot be discriminated. One is tempted to say that all chorea proper results from interference, temporary or persistent, in the same (Rolandic?) area.

The last case of Huntington's chorea I saw was in Tunis. I happened to be at the window of my hotel, which looked on a narrow lane, when I saw a native, evidently afflicted with this malady, shuffling along and edging himself for support against the opposite wall. The movements as he walked became more and more violent, until, feeling himself shaken off his legs, he backed into a doorway, where leaning against the doorpost he scuffled down into a sitting position; there the poor fellow sat twitching, jerking and grimacing until in a few minutes the violent phase passed off; then, scrambling to his feet, he staggered off. I followed after him but failed to catch him. Accordingly I asked X. Y. if at times the agitation became such as to shake him off his legs, and he and his son—without whom he does not venture abroad—said at once that such was often the case with him.

The prognosis, even if the case be not inherited, is very grave; the muscles of mastication and speech become affected, and gradually, after many years it may be, the mind falls into degeneration, so that after many years, directly or indirectly, it proves mortal, the last phase being one of utter wreck. If in this case the fall were the cause of the attack, the outlook may be better than in a case of "spontaneous" origin: the symptoms may abate, and the tissue changes be arrested. No remedies known to us are of any value; scarcely even palliative. The

pathologists who have had the opportunity of examining the nervous centres after death tell us that distinct marks of feebly inflammatory decay are not inconspicuous in the brain; the spinal cord being normal. Especially in the Rolandic area signs of a slow pia-arachnitis are found, with degeneration of the cortical cells and some chronic cell proliferation. There are no affinities of this disease to rheumatic fever, but it would seem to be a result of some infection. In this case, as in others of the kind, the heart is unaffected. The causes of the malady are in complete obscurity; the discussions of its antecedents in the textbooks are trivial.

THE NECESSITY FOR FULLER CONSIDERATION OF THE LOCAL PROCESSES OF DISEASE AND REPAIR IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

BY

H. MORRISTON DAVIES, M.D., M.C.CANTAB., F.R.C.S.,
CAPTAIN R.A.M.C.(T.),

CONSULTING SURGEON, UNIVERSITY COLLEGE HOSPITAL AND CITY
OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

THE recent discussion at the Medical Society of London, together with the leading article in the *BRITISH MEDICAL JOURNAL* of December 8th, 1917, have served to focus attention on the fact—which has been becoming increasingly plain for some time—that the sanatorium treatment of pulmonary tuberculosis is not fulfilling all the hopes of those who believed that in it a really satisfactory treatment had at last been attained, and that by it the therapeutic problem of consumption had been definitely solved. The method has had a long and thorough trial, but it must now be recognized that the results of it are not such as to justify us in continuing to regard it as a standard method, adequate to deal with the disease with reasonable success, and without radical improvement or addition. We cannot say that in the average case treated by sanatorium methods complete and permanent cure is the normal event. In any given case the result of the treatment is uncertain and extremely difficult to foretell; the immediate mortality remains considerable, the ultimate mortality large, while our power of completely arresting the disease and of restoring the patient to active life is still disappointingly capricious. While we are able in a large number of cases to produce the most gratifying improvement in the general condition and diminution of the symptoms, it must be admitted that the tendency to the persistence of some few signs or symptoms and to ultimate relapse after the resumption of working conditions are disappointingly common.

It is the object of this paper to inquire into the significance of the comparative failure of sanatorium treatment and to indicate some principles which that treatment ignores, but which must be taken account of before we can hope to establish a method in any sense definitive.

GENERAL PATHOLOGICAL CONSIDERATIONS.

In dealing with the problems presented by the treatment of pulmonary tuberculosis it is necessary to keep in mind constantly and vividly the general pathological features of the disease. Certain broad and quite elementary features of the processes involved in the disease will therefore be recalled. The application of these facts is so obvious, and seems when written so helpful, that no apology will be made for giving some account of them here. A familiarity with the pathology of consumption is usually taken for granted, and is therefore but little referred to in discussions upon treatment. A critical consideration of such discussions will, however, frequently reveal evidence that such pathological elements are, in fact, not always kept steadily and clearly in mind, and even that the appreciation of them is sometimes imperfect or confused.

The tubercle bacillus, when it infects man, shows itself to be an organism of slight general toxicity and slight local virulence. It does not in itself produce marked constitutional symptoms and the fever that it so commonly

causes is benign even when considerable in degree; similarly, the presence of the organism in the tissues has remarkably little direct destructive effect (as compared with the pyogenic organisms, for example), but rather stimulates them to produce a special tissue, the function of which is to surround and destroy the invading micro-organisms. This special tissue is, of course, granulation tissue and constitutes the well-known granuloma of tuberculosis. It is essential to grasp clearly the peculiarities of this tissue. It has no feature peculiar to tuberculosis, but is the normal response of the body to a mild continuous irritation. The function of the granuloma is to dispose of the irritant by destroying it, and its destiny, like that of all other granulation tissue, is, when its work has been accomplished, to be converted into fibrous tissue. If a few tubercle bacilli be introduced into a healthy tissue, the normal sequence of events is the formation of a granuloma round the bacilli, the destruction of the latter by the granuloma, and the direct development of the latter into a small healthy scar. Now we can define with fair precision the conditions necessary to ensure this sequence of events: (1) The general resistance of the patient to tuberculosis must be good; (2) the dose of the organism must be reasonably small; and (3) the part infected must be kept under certain local conditions known to be favourable to cure, of which by far the most important is a state of rest. When these three requirements are not satisfied the granuloma as a protective mechanism fails and becomes itself an agent of injury. Supposing such a failure to occur either from low general resistance, largeness of the dose (or what may virtually be the same thing, exceptional virulence of the organism), or unsatisfactory local conditions, the result is a progressive enlargement of the granuloma.*

This has two important consequences:

1. The granuloma enlarges at the expense of the surrounding healthy tissues, which it attacks and destroys, as it were to make room for itself, with a vigour approaching that of a malignant tumour. This is the mechanism whereby tuberculosis produces its destructive effects, which are then seen to be part of the actual defence against the disease. As is well known, the destructive effect of the enlarging granuloma is not equal against all tissues and is apt particularly to be restrained by any dense fibrous membrane and by the parietal pleura—a feature which is one of the few absolutely characteristic of tubercle.

2. The granuloma from its very nature draws its blood supply chiefly from capillaries, any other vessels it may receive being very imperfectly developed. The consequence is that when the granuloma reaches any considerable size the central parts become very feebly nourished and therefore undergo fatty degeneration with consequent caseation and liquefaction. As long as caseation has not occurred, direct conversion of the granuloma into fibrous tissue is still possible under favourable conditions; recovery with loss of tissue but without loss of substance then takes place. When caseation has occurred there is necessarily loss of substance as well as loss of functioning tissue. There is thus actual cavity formation, and recovery is no longer possible without diminution in volume of the affected part. When the irritation caused by the micro-organism is very mild the tendency to the direct conversion of the granuloma into fibrous tissue is very strong and is in action continuously, even though the disease is progressing. The lesion then much more closely resembles the syphilitic gumma than the traditional caseous tubercle. This continuous fibrous transformation is probably the mechanism that leads to fibrous phthisis and the fibrosing tuberculosis of lymphatic glands.

The fibrous tissue into which the successfully resistant granuloma ultimately is transformed tends, of course, to contract and to diminish the volume of the affected part, even although there may have been little or no caseation and loss of substance. Diminution in volume of the lung is thus seen to be an essential feature of recovery from phthisis; it is, as we have seen, rendered necessary in two ways—through actual loss of substance of the organ in consequence of caseation, and through the contraction which must accompany the conversion of granulation tissue into a mature and healthy scar. So essential a part

* I set aside for the moment the possibility that the failure of local control of the disease may be so complete that a generalized tuberculosis occurs.

of this conversion is the process of contraction that if the latter be prevented the actual formation of fibrous tissue will ultimately be arrested. This can often be seen in cases of chronic ulcers surrounded by much rigid induration or fixed to a bone. Here the inability of the newly formed fibrous tissue to contract is often demonstrably the sole cause of the arrest of healing. Thus some shrinkage of the lung is an essential part in the actual process of recovery. If the necessary shrinkage is no more than is rendered possible by the falling in of the chest walls, costal, phrenic, and mediastinal, and other circumstances are favourable, recovery proceeds satisfactorily. If the necessary shrinkage is greater than can be readily and without undue delay compensated thus, the contraction, which naturally always tends more or less to pull on the walls of the intra-pulmonary bronchi, must now occur chiefly by means of this factor. Thus when shrinkage is embarrassed not only is the actual healing of the tuberculous process unfavourably affected, but a complication—distortion and dilatation of the bronchi—is apt to be set going, which may, even if the patient is able completely to throw off his tuberculosis, prove as disabling as the primary disease.

One further fact in the natural history of scar tissue should perhaps be borne in mind: While contraction is indispensable during the formation of a healthy scar, such fibrous tissue once formed and fully mature can by constant and gentle tension be stretched permanently to almost any degree.

FACTORS OF TREATMENT.

The foregoing pathological considerations have indicated that there are three main lines along which the treatment of pulmonary tuberculosis must be discussed: (1) The influencing of the general resistance of the body to tuberculosis. (2) The means whereby the local conditions can be made favourable to the healthy evolution of the granuloma as a defensive mechanism. (3) The special importance in the case of the lung of the contraction which accompanies all healthy scar formation and the necessity of providing for its occurrence if healing is to be satisfactory and bronchial deformation to be avoided. We thus have three fairly distinct problems to consider—the general problem, the local problem, and the mechanical problem.

The General Problem.

Sanatorium treatment as such concerns itself solely with attacking the disease through increasing the general resistance. The avoidance of reinfection and intercurrent respiratory infections, the hygienic life, and the use of exercise, are its chief weapons. We have enough evidence to-day to conclude that powerful as these weapons are they are not able in an average case to guarantee success or to obtain it often enough to enable us to hope that any degree of detailed improvement in the method will give us a definitely effectual treatment.

The subject of the general resistance to tuberculosis in man is still very far from being fully understood. It is probable that most people living under the conditions of present day Western civilization are infected with tubercle at one time or another, though in the great majority the disease never becomes recognizable during life. It is to be presumed that the development of clinically recognizable tuberculosis is an evidence of a resistance less than normal. We may suppose that, occasionally, a power of resistance greatly below the normal is inherited. Such individuals would be found out by the disease early in life, and they probably account for the cases of general tuberculosis of infancy and early childhood.* Those who escape this danger otherwise than by mere accidental avoidance of infection are to be regarded as having a definite general resistance to the disease. In the great majority of people this resistance is strong enough to crush any early infection before it becomes clinically recognizable. In a minority the resistance must be near or below the point where this extinction of the disease in a larval stage is possible. Such persons are those who develop clinically recognizable phthisis. Cases of very rapid and intractable disease probably represent individuals in whom the resistance is exceptionally low, and near the point that would permit of a primary generalized infection. Intermediato

degrees of immunity will produce types of the disease of corresponding severity. At the top of the class will come individuals whose resistive powers are nearly adequate to deal effectively with an infection in its larval period. Now there is a good deal of evidence that the general resistance to tubercle varies, within limits, with the general health of the individual. The improvement in the general health effected by sanatorium treatment progresses in certain favourable cases *pari passu* with improvement in the disease. It is probable, therefore, that the (comparatively limited) class of cases curable by sanatorium treatment is made up of individuals whose resistance is nearly or quite normal—that is, who are by nature nearly or quite able to dispose of the infection in its earlier stages, but who have had their resistance temporarily depressed by a decline in general health with which the infection has coincided. It is to be feared that this class is limited, for the concurrence of circumstances necessary to produce it is somewhat complex—namely, a natural resistance quite near the normal, a depression of this resistance through the general health, and the acquisition of the infection just at this moment.

That the effect of the general health in heightening the resistance to tubercle is quite limited is shown by the numerous cases in which, under sanatorium treatment, there is a great improvement in the general health and no corresponding improvement in the disease. Here we may suppose the natural resistance to be low and quite outside the narrow range of influence of the general health.

The Local Problem.

It is a fact very familiar to surgeons that in cases of so called surgical tuberculosis in parts subject to movement, such as bones, joints, and tendon sheaths, immobilization of the part has a remarkably favourable effect on the disease. Without any other treatment it may render the granuloma completely effective as a defensive mechanism, causing it to cease to enlarge, to become less liable to caseation, and to undergo fibrous transformation in the normal way. General treatment to raise the power of resistance is by itself quite useless in these cases, and no surgeon of experience, if compelled to choose in a given case between it and immobilization, would hesitate for a moment in preferring the latter. Doubtless general treatment reinforces local treatment strongly, and should, of course, always be used if possible, but the indispensable condition for recovery in a part subject to movement is immobilization. There is no reason to suppose that these principles are not equally applicable to tuberculosis of the lung. The element of motion in the affected part is even more conspicuously present than in the case of a joint. That general treatment alone is sometimes effective in spite of continued movement suggests that the lung, probably on account of its vascularity, is naturally unfavourable to the disease; that general treatment alone frequently fails suggests that the local factor, which is indispensable in the case of a joint, is also necessary here. Surgeons have learnt that the immobilization of a tuberculous joint to be efficient must be absolute, and the same may be expected to apply to the lung. It is certain that the relative diminution of movement obtained by keeping a patient in bed has no claims whatever to be regarded as possessing any of the qualities of true immobilization as applied to a joint.

The Mechanical Problem.

It is a fortunate coincidence that the means whereby alone can be effected the institution of absolute rest in a diseased lung are also the means whereby the requirements of healing and the solution of the mechanical problem can best be met. The collapsed lung is not only immobilized but is in a condition to undergo the necessary shrinkage which accompanies the formation of healthy fibrous tissue; thus are promoted by one and the same measure the effective functioning of the granuloma as a protective mechanism, its due transformation into fibrous tissue when its function is fulfilled, and the prevention of the transformation leading to that distortion of the internal structure of the lung which is so apt to cause a permanent and disabling bronchiectasis.²

* Apart from its occurrence in early life, general tuberculosis seems mostly to be a terminal phenomenon, setting in only when the general resistance has been broken down by very extensive local disease.

² The importance of the mechanical factor and of the treatment of it is so great that I have dealt with it separately in another paper published in the *Quarterly Journal of Medicine*, April, 1918.

The effect of each of the four methods of treatment which I shall mention directly is to put the whole or part of the lung either temporarily or permanently out of action, and at the same time to compensate for the mechanical disabilities which have been produced by the morbid changes. Two of these methods have for their object the collapse of the whole of one lung; they are nitrogen displacement, which collapses the lung only, and rib mobilization, which collapses the lung together with the chest wall. The other two influence a part of the lung only; the one is division of the phrenic nerve in the neck, which produces paralysis of the diaphragm and is followed by immobilization and a partial collapse of the lower lobe; the second is the local replacement of one part of the lung, usually the apex, by a foreign body (Tuffier).*

Nitrogen Displacement.

Although each of these methods reduces the mobility and compensates for the disabilities caused by the mechanical factor, yet the selection of the type of case which will benefit by any of these methods of surgical intervention, and the choice of which method will produce most efficient results, is a matter of great importance. The lack of greater appreciation in this country of the value of the simplest even of these four procedures, nitrogen displacement, is the result of an imperfect realization of the character of the pathological processes and of the seriousness of the mechanical disabilities, and of the fact that the effect of the treatment is directly antagonistic to the further development of the former while at the same time it compensates for the latter.

The effects of the collapse of the lung are, as I have said, twofold. In the first place, it arrests in that organ the movements associated with respiration, and, as collapse is followed by a striking diminution in the symptoms, it reduces greatly the very active and sudden movements which accompany the acts of coughing and expectorating. As the granulomata are, therefore, no longer subject to continual irritation and injury by the movements of the tissues in which they are situated, they are able to perform their protective function, the fibrosis is able to overtake when their work is done, and to convert them into healthy fibrous tissue. In the second place, the collapse allows the newly-formed fibrous tissue to contract. It prevents, therefore, the constant drag on and the distortion of the surrounding walls, and, more important still, the bronchial deformation. It allows also of the obliteration of cavities in the bronchi or parenchyma and so abolishes the absorption of the products of secondary infection; the beneficial effect of this on the constitution and so on the power of resistance is obvious.

An extensive invasion of both lungs by tubercle is the only contraindication which I recognize to the treatment of this disease by nitrogen displacement. If the facts which I have stated above are accepted, it must necessarily be allowed that it is the extensiveness only, and not the slightness of the lesion, which constitutes a grave and serious objection to the attempt being made. The problems how early a case and how soon after the symptoms have been recognized nitrogen displacement should be tried will probably remain subject to controversy for many years. So long as a case is an "early" one—that is, so long as the diminution in the volume of the lung can be balanced by processes of nature (the approximation of the boundary walls and emphysema of the adjacent healthy lung)—there is no necessity for artificial means to compensate the disabilities due to the mechanical factor. But there is still the local problem—the granuloma—which must be considered. It may be, in a given case, that improvement in the general health and the moderate increase in resistance this can effect, will be sufficient. If, however, the symptoms and the signs indicate that there is delay or incompleteness in the fibrosis of the granuloma, more complete rest of the lung by surgical intervention is undoubtedly indicated.

Another argument in favour of the early treatment of pulmonary tuberculosis by nitrogen displacement is

that the longer it is postponed the more probable is it that the collapse of the lung will be incomplete or impossible owing to adhesions. Interpleural fibrosis often interferes greatly with the treatment. If, however, the adhesions are few and are accessible for division, or can be stretched sufficiently to enable the lung to be reduced to about half its volume, great benefit may be expected and can be obtained from the partial collapse.

Rib Mobilization.

This is an alternative method of treatment, but as the collapse of the lung and the chest wall is permanent, and as the operation is much more serious, it must be considered only when collapse by nitrogen is impossible. All cases which can be treated by nitrogen displacement are not suitable for rib mobilization. Much more rigid selection is necessary, and active disease in the opposite lung is an absolute contraindication. The immobility of the lung obtained by rib mobilization is more complete than that obtained by nitrogen, as the variations in the size of the organ due to the absorption of gas from the pleural cavity and the periodic refills are absent.

Division of the Phrenic Nerve in the Neck.

This operation is followed by paralysis of the diaphragm on the same side. The dome rises up into the thorax one or one and a half inches above the normal level. During quiet respiration it is motionless, but during a deep inspiration it may ascend still further into the chest. The movements of the lower lobe are controlled by the diaphragm. Paralysis of this muscle abolishes, therefore, the movements of the base of the lung, and at the same time produces partial collapse. This operation is of great value under the following circumstances:

1. When there are extensive secondary changes (mechanical and infective) in the lower lobe.
2. To diminish movement in the lower lobe when it is the seat of primary tuberculous disease.
3. To prevent the aspiration of infective material (tuberculous or pyogenic) from the upper into the lower lobe.
4. Although it is not germane to the subject of this paper, it should be added that paralysis of the diaphragm may be of considerable value as a prophylactic measure against the development of bronchiectasis in cases of chronic interstitial pneumonia.

Insertion of Foreign Body.

Tuffier advocates local collapse of the lung by separating the parietal pleura from the chest wall, and filling the space thus formed by a foreign body, such as a lipoma or fibroma.

It is frequently stated that one of the great barriers to success in the sanatorium treatment of pulmonary tuberculosis is the desire of or the necessity for the patient to return to the environment in which he was when he contracted the disease. The conditions which surround the individual when he returns to his work can rarely be so favourable for maintaining the degree of resistance to the disease acquired while under treatment. His reserves become exhausted by overwork, underfeeding, irregular hours, anxieties, or infection such as cold or influenza, and the granuloma once more fails in its defensive function. It is clear, therefore, that when the treatment is confined to improvement in the general health of the patient and to increase in the resistance only it is unsatisfactory, and in a large majority of cases the benefit which is obtained must be temporary in character. But when the lung is collapsed by nitrogen, the tuberculous lesion is set at rest and the mechanical disabilities are compensated, the patient is to quite a considerable extent independent of those fluctuations in his general health which are inevitable. Once, moreover, the initial treatment is completed, he can return to his work and can lead a comparatively normal existence with much greater safety to the community and with at the same time a much more considerable hope of maintaining and of securing the improvement which he has acquired, and possibly even of becoming the master of, instead of the slave to, the disease.

* I have already dealt with the details of the technique of all these methods in various other articles: "The therapeutic value of gases introduced into the pleural cavity," *BRITISH MEDICAL JOURNAL*, April, 1914; "The operation of rib mobilization in the treatment of phthisis," *British Journal of Surgery*, vol. ii, 1915; "The importance of the mechanical factor in the treatment of pulmonary tuberculosis," *Quarterly Journal of Medicine*, April, 1918.

THE IMPORTANCE OF REGULATING THE FAT-INTAKE IN DIABETES MELLITUS.

BY
P. J. CAMMIDGE, M.D. LOND.

THE dietetic treatment of diabetes mellitus has passed through three stages, progressing from a simple problem with one unknown quantity to its present position of a complex investigation involving the determination of at least two additional factors.

The first stage was initiated by the accidental discovery made by Rollo, in 1797, that glycosuria could be controlled by the exclusion of vegetable foods from the diet, but it was not until the relation between the digestion of carbohydrates and the formation of sugar was established by Gmelin and Tiedemann, in 1838, that the treatment of the condition by limiting the carbohydrate intake was placed on a rational basis. The discovery by Lépine and Barrah, in 1891, that sugar could also be derived from proteins paved the way for the second stage in the treatment, for their experiments and the clinical observations of Kolisch and Schumann-Leclercq (1903) showed that regulation of the protein as well as the carbohydrate is necessary if the progress of the disease is to be checked, especially in severe cases. Until very recently the third important constituent of the diet, fat, has been regarded as a comparatively innocuous food for diabetics; they have consequently been given it in large quantities and encouraged to consume as much as possible with a view to maintaining their weight and, if possible, increasing it. The most recent experimental and clinical investigations have shown, however, that control of the fat allowance is quite as important as regulation of the carbohydrate and protein intakes if a gradual failure of metabolism with ultimate return of the glycosuria and progressive acidosis are to be guarded against.

Diabetic Lipaemia.

When phlebotomy was commonly practised it was known that the blood in severe cases of diabetes occasionally had a milky appearance, and that on standing a creamy layer of fat separated out on the surface. Although such a condition of lipaemia is very rarely seen in any other disease than diabetes no great importance has been attached to it, save that it indicated a grave prognosis, and until recently no attempt has been made apparently to study the fat content of the blood systematically to discover the antecedent stages and ascertain whether an excess of fat, without obvious lipaemia, existed in all cases of diabetes. The first comprehensive series of cases in which such an investigation was carried out was reported in 1916 by Bloor,¹ who had previously studied the fat content and relations of the blood in a number of normal individuals and other pathological conditions by methods specially developed for the purpose, and so was in a position to make reliable comparisons. He found that out of the thirty-eight diabetics investigated a lipid value of the blood in excess of the normal average was present in thirty-six, and in all but three of these it exceeded the highest limit met with in healthy persons, in spite of the fact that a characteristic milky appearance was found in only two instances. A marked increase, up to 100 per cent. or more of normal values, was found in all the severe cases, but clinically mild cases also sometimes showed considerable abnormality. As a rule, however, the more severe and long-standing the diabetic condition the more marked was the abnormality in the blood lipids.

From these results it would appear that an excessive lipid value of the blood is very common in diabetes, and that it may be regarded as an almost constant phenomenon of the diabetic condition. This being so the questions that arise are: What is the source of the excess of fat? and What is its significance? The evidence at present available suggests that it originates mainly in the fat of the food, and that the probable reason for its appearance in the blood is a partial failure of the mechanism for dealing with fat arising from the essential nature of the diabetic state, like the associated defects in carbohydrate and protein metabolism. The dependence of lipaemia on the fat content of the diet was well shown in Bloor's two cases of obvious lipaemia, which promptly cleared up when a fat-free diet was substituted for the fat-rich diet they

had been taking previously; and similar observations have been made by Allen, who has pointed out that dogs rendered diabetic by partial removal of the pancreas rarely show lipaemia unless precautions are taken to ensure good digestion, and that it then varies with their digestive powers, appearing readily on feeding them with fat and ceasing promptly on its omission. Allen has shown also that the excess of fat in the blood in diabetes is not due to hyperglycaemia, nor solely to removal of pancreatic tissue, and that absence of carbohydrate or loss of sugar from the body do not appear to be responsible for the condition, since maximal phloridzin poisoning followed by feeding with nothing but fat in dogs fails to produce anything resembling diabetic lipaemia. Bloor found that there was no definite relation between high blood lipids and the occurrence of acetone bodies in the urine, although he points out that maximal lipaemia probably never exists without acidosis, because acidosis goes with the general severity of the diabetes. That diabetic lipaemia is not due to change in the reaction of the blood is indicated by the fact that the greatest possible reduction in its carbon dioxide capacity by acid poisoning produces no characteristic change in that direction. It would therefore seem that the tendency to the imperfect utilization of fat in diabetes is not dependent upon any other feature of the disease, but is a primary phenomenon of the condition which appears to vary independently of the other symptoms, although its extent corresponds roughly to the severity of the disorder.

Ketonuria.

The existence of an excess of lipoids in the blood in most cases of diabetes suggests that the mechanism by which fat absorbed from the bowel is taken up by the cells of the body is usually more or less at fault, but there is another point in fat metabolism at which failure frequently occurs also—namely, its oxidation in the tissues. This is indicated by the presence in the blood and urine of imperfectly oxidized products in the shape of the acetone bodies (acetone, aceto-acetic acid, and beta-hydroxybutyric acid), which have been aptly likened by Woodyatt to the smoke from a badly burning candle or fire. The work of Rosenfeld, Hirschfeld, Geelmuyden, Magnus-Levy, and others has shown that the principal source of the acetone bodies is fat, and it may be taken as proved that the presence of acetone and its associates in the urine and blood is mainly influenced by the amount of fat in the tissues, and hence in the food.

It is well known that the fasting human subject shows ketonuria, and that the available store of fat in the body is one of the chief sources of the condition under such circumstances was strikingly demonstrated by the experiments of Folin and Denis² with fasting obese women in whom marked acidosis and serious symptoms of acid poisoning corresponded to the rapid loss of weight resulting from starvation. Ketonuria likewise results from simple carbohydrate abstinence, and it would seem that a certain proportion of available carbohydrate is necessary for the complete and orderly combustion of fat by the tissues. According to Zeller,³ a molecule of sugar must be oxidized for each two molecules of fat, which would mean in a normal individual the ingestion of one part of carbohydrate for each four parts of fat. If carbohydrate is not available the sugar derived from the constituent amino-acids of proteins may be used, and it is for this reason that proteins are antiketogenic in normal persons. They are less efficient for the purpose than carbohydrates, for some amino-acids are themselves capable of giving rise to a considerable proportion of acetone bodies. In the diabetic subject the degree to which fat is completely utilized depends upon the relation between the power possessed by the tissues of making use of the sugar offered to them and the amount of fat taken in the diet, or stored in the body. If carbohydrate foods are comparatively well metabolized, a considerable amount of fat can be burned without "smoking" or giving rise to acidosis; if the defect is more pronounced and only a small quantity of carbohydrate can be made use of, a proportionately smaller quantity of fat can be taken without being imperfectly oxidized, while if the tolerance for carbohydrate is slight ketonuria and acidosis occur with even a small amount of fat in the diet, or with no fat at all, since more or less of the carbohydrate or protein

origin is probably also being excreted in the urine as sugar, and there may not be sufficient available to suffice even for the complete oxidation of the protein fractions that give rise to acetone bodies.

It may consequently be taken as a general working rule that fat unbalanced by an adequate available supply of other foods is poison to the diabetic, and it therefore follows that the craving for bread and other starchy foods shown by patients on a high protein-fat diet is rather an expression of a natural want hitherto misunderstood than an evidence of original sin that can be dealt with more satisfactorily by restoring a proper balance in the diet by reducing the fat than by increasing the carbohydrate, as is usually taught. Owing probably to a latent reserve power possessed by most people, diabetics can generally be trained to utilize gradually more fat, but their reserve power in this respect is not unlimited, and, like the tolerance for carbohydrates and proteins, is easily overstrained, with rapidly increasing acidosis and death from coma.

Fat and Sugar Utilization.

A third aspect of the fat problem in diabetes that has been reinvestigated lately is the influence exerted on sugar utilization. It has been contended by some writers that sugar can be formed from fat, since the addition of fat to a diet that has previously been well borne may increase the glycosuria in diabetes; but the experiments of Ringer, Allen and DuBois, and others are strongly against such a transformation taking place in animals or man, so that some other explanation must be sought. Recent experiments carried out by Allen⁴ appear to have solved the mystery. He found that if two dogs are made diabetic by removing corresponding portions of the pancreas from each, and, after their carbohydrate and protein tolerance has been determined, one is given only just sufficient fat to prevent loss of weight, while the other is allowed as much as he will eat, or is forcibly fed with fat, the former, although thin and always hungry, will remain sugar-free, whereas the other gains in weight, appears healthy and happy, but eventually develops glycosuria, with ultimately fatal results, unless the fat feeding is promptly stopped and he is starved until the glycosuria is controlled. Contrary to what might have been expected if fat were transformed into sugar in the body, examination of the blood of such dogs shows that the first effect of adding fat to the diet is to reduce the percentage of sugar. As the fat feeding is pushed and the weight of the animal increases, a parallel rise in the level of the blood sugar takes place, however, and finally glycosuria occurs. An abnormally high blood-sugar level may exist for some time before sugar appears in the urine, and persist for a considerable interval after all fat has been omitted from the diet, suggesting that an excess of fat reduces the permeability of the kidneys for sugar, and showing that its evil effects continue long after the cause has been removed, thus probably explaining the diminishing glycosuria, without a corresponding fall in the blood sugar, of chronic cases of diabetes kept for long on a diet with a high fat content.

These experiments have been repeated under such a variety of conditions and with such adequate controls, always with similar results, that it seems reasonable to conclude that the hyperglycaemia and glycosuria following excessive feeding with fat are due to a failure of metabolism consequent on the gain in weight above what the defective assimilative functions of the animal are able to cope with, and that any attempt to induce a high level of nutrition with fat results in an aggravation of the diabetic condition similar to that which follows a like attempt with carbohydrate or protein, although its effects are slower and more insidious.

Applications to Treatment.

The application of the results of the observations outlined above to the clinical treatment of diabetes mellitus obviously entails the forsaking of several cherished beliefs and standards. It will also involve very considerable modification in current methods of determining and regulating the diet, even the most modern. We can no longer consider that we have done our duty by our patients if we have merely rendered their urine sugar-free by limiting the carbohydrate intake or adjusted the protein allowance

to their metabolic capacity; we must now also ascertain the optimum amount of fat which will meet their needs, prevent acidosis, and avoid the onset of glycosuria, either immediately or in the future.

The prevention and control of acidosis is so often a matter of primary importance when patients come under observation that it will be well to consider it first. It has long been known that it is dangerous to change a severe case of diabetes suddenly from an ordinary mixed diet containing carbohydrate to one consisting of protein and fat alone, as serious acidosis may develop, but it does not appear to be generally recognized that it is often equally dangerous to deprive a patient of all food and adopt the fasting treatment without adequate preparation. In order to prevent acidosis occurring, and avoid increasing it when already present, the chief source of the acetone bodies, fat, should first be eliminated from the diet as far as possible. After a day or two on a fat-free diet the carbohydrate may generally be reduced with safety, but it is not wise to leave out all carbohydrate until the protein intake has also been brought down by at least half. Both carbohydrate and protein may then be gradually reduced until a diet of low-value green vegetables only is being taken, when, if the glycosuria still persists, actual fasting may be instituted without fear of grave complications developing. When the diet is being built up again and the patient's tolerance is being tested after the glycosuria has been controlled, fat should be introduced with equal care, none being allowed at all until a fair tolerance for carbohydrate and protein has been established. The fat content of the diet, like the carbohydrate and protein, must then be worked out each day and the effect of every addition be carefully watched.

Unfortunately the results of analyses of the urine do not afford information that is of much help in regulating the allowance in many cases, although variations in the total acidity, true ammonia nitrogen, calcium, and magnesium excretions, with increase in the total output of acetone bodies may give useful indications in some instances, and show that the fat is being increased too rapidly. As a rule the most reliable information is given by examination of the blood. Allen's experiments on dogs have shown that a rising blood-sugar curve with increasing weight when fat is being added to the diet indicates approaching failure of metabolism with eventual glycosuria, but earlier and more certain information that the mechanism for dealing with fat is being overloaded can be secured by estimating the lipid value of the blood by Bloor's method or, since it has been found that the cholesterol increases parallel with the fat, by cholesterol determinations. When the apparatus and time for blood analyses are not available, the fat allowance must be regulated by the patient's weight and the appearance of sugar in the urine.

It must be borne in mind, however, that weight is not necessarily a true index of the tissue mass of the body as it is influenced by accidental circumstances, particularly loss and retention of water, and that glycosuria is a late symptom of failure of metabolism due to excess of fat in the diet.

If sufficient care is taken, glycosuria can usually be avoided if the fat-intake is so adjusted that, while further loss of weight is guarded against, progressive gain is prevented. This ideal, which should be aimed at in all cases, is quite contrary to the older teaching, according to which increase in weight was, above all other things, the most desirable for a diabetic, since it was considered that gain in weight meant gain in strength also. That such is not really the case has been shown by the experiments of Williams⁵ with the Collin dynamometer. It appears from his results that, as a rule, diabetics are physically distinctly weaker than normal persons, owing partly to loss of musculature, but also probably in consequence of the diminished supply of energy furnished by the imperfectly utilized food to the muscular mechanism they possess so that it is incapable of functioning normally. There appears to be a direct relation between the food tolerance and the muscular vigour of the patient, and if the tolerance is depressed by the continued use of a diet beyond his metabolic capacity further decline in the physical powers takes place, whereas if the food tolerance is increased by the employment of a diet within the physiological limitations of the individual, even though it falls far short of the theoretical energy requirements of

the body, an appreciable increase in muscular tone occurs.

Overfeeding, therefore, is not only a cause of glycosuria in diabetes, but also results in a progressive failure in metabolism with loss of strength. It appears to matter little whether the excess of food is in the form of carbohydrate, or protein, or even fat—the outcome is the same; but as the effects of an excess of fat are more insidious and difficult to recognize in the early stages it is necessary that particular care should be taken in regulating the fat allowance. Since I realized that fact and applied it in my clinical work I have obtained much better and more permanent results than formerly. It has also enabled me to recognize and deal with cases of recurrent glycosuria that would otherwise have been puzzling. As an example I may quote the case of a boy of 14 who was brought to me in October, 1916, by Dr. J. Howard Cook.

When he was first seen by Dr. Cook he was passing about 100 grams (5.5 per cent.) of sugar a day, but when he came to me the sugar excretion had fallen to about 10 grams a day. The patient's carbohydrate and protein tolerance were worked out, and he was put on a diet on which he remained sugar-free for about three months. A return of the glycosuria then occurred, but on his carbohydrate allowance being readjusted the sugar disappeared, and it remained absent for about four months. As the glycosuria then recurred it was evident that his carbohydrate tolerance was steadily falling, and the prognosis appeared to be bad. A further readjustment of both the carbohydrate and protein allowance kept him sugar-free for another four months, when sugar was again found. I went into the case very carefully with Dr. Cook, and we came to the conclusion that as the boy's weight was increasing more rapidly than would probably be accounted for by natural growth and a considerable amount of fat was being taken in the diet, it would be advisable to try the effect of reducing it. This was at once done, and I hear that he has since remained free from any trace of sugar although more starchy food has been taken, and that he has improved in strength and general condition.

The importance of a strict control of the fat content of the diet has been impressed upon me by a number of other cases, including several which had been submitted to the fasting treatment with immediately satisfactory results, but with ultimate return of the sugar. In some of these that have come under my care owing to the recurrence, I have found that an excess of protein was being taken, but in others careful chemical examination has shown that the fat content of the diet was the difficulty, and when it was adjusted to the patient's metabolic powers the glycosuria promptly ceased and did not return.

Patients who are steadily losing weight, as most diabetics are, naturally desire to put on flesh as quickly as possible, and are apt to judge the success or failure of any treatment they may undergo by the extent to which their wish is gratified; but, although we may understand and sympathize with their longing, it must not be gratified, and we should explain that gain in bulk is a sign of failure rather than of success. A steady weight that can be maintained without overtaxing the patient's defective metabolic powers should be aimed at, and any attempt to improve a bad situation by overfeeding, or even feeding up to the theoretical caloric requirements of the body, must be abandoned. Gain in weight must be sacrificed to well-being and satisfaction of the appetite to length of days. Individualization of the diet, in which the allowance of carbohydrate, protein, and fat is regulated by the tolerance of the patient for each, and by his powers of dealing with the diet as a whole, is the line along which the treatment of diabetes is developing, and, although it is very likely that we have not yet reached finality and that other considerations, such as the mineral content of the diet and the amino-acid make-up of various proteins, etc., will eventually have to be taken into account, it is clear that the older standards and empirical methods employed for so long are doomed, and will have to give place to scientific dieting based upon exact modern chemical research and knowledge.

AN OUTBREAK OF PHLEBOTOMUS FEVER.

BY

CAPTAIN J. A. HARTLEY, M.D. DUBL.,
R.A.M.C.(T.F.).

AN outbreak of phlebotomus fever (sandfly fever) occurred in a squadron of yeomanry on outpost duty in mid-Egypt in the middle of the summer of 1917. The post was on the western edge of the cultivation, and I was in medical charge of the unit. Of the total strength 86.4 per cent. were infected. The first to contract the illness were the men, non-commissioned officers next, and officers last. The first case was discovered on the thirty-seventh day in occupation, and from this there were three or four fresh cases daily for a week, and an average of six daily in the second week. For medical reasons the unit then moved about a mile and a half to a new camp on fresh ground, and, although it was impossible to avoid carrying the infection, better conditions followed. For military reasons it was desirable to maintain occupation of the first position, and after taking preventive measures additional to what had already been followed, a guard drawn from another unit was placed in it. Four days had scarcely elapsed when the non-commissioned officers and men who formed this presented symptoms of infection, and the illness spread through all of them.

The accommodation consisted of a dwelling-house and offices which the officers and non-commissioned officers occupied, and shelters constructed of wood and canvas for the men. All were placed compactly on an elevated site adjacent to a pool which covered about an acre and contained more or less stagnant water. Agricultural drains of muddy water were in touch. The sanitary arrangements were satisfactory except the drinking water, which was bad; the latrines and horse lines were at a reasonable distance. Preventive measures were adopted in the form of cresol spraying throughout, and the use of paraffin oil on breeding places. Everyone, officers and other ranks, had a mosquito net, but this could not be counted on as the midge is so small that it can pass through the mesh. They were plentiful, very small and midge-like, with hairy bodies. They were found on walls and in rubble, but the breeding places must be moist.

The incubation period was from four to seven days. The onset was very sudden, accompanied with severe malaise, headache, and suffusion about the eyes and post-orbital pain. Pain in the lumbar region was generally intense, and pain and cramp in the limbs occurred. Constipation was nearly always present and profuse sweating. The temperature rose quickly to 102.5° or 103°, and on a few occasions to 105°. After twenty-four hours the pyrexia diminished, and at the end of three days fell to normal. The pulse was not correspondingly accelerated—it was seldom above 80; it became soft and weak and the cardiac condition required attention.

The suddenness of the onset was the marked feature. A man to all appearances in normal health was on duty at 9 a.m., and an hour later reported ill with giddiness and inability to carry on. His temperature was 103° F.; other symptoms developed in the course of an hour or two. One night another was found on horseback wandering up and down the road, unable to recall to mind the way he was accustomed to take to reach camp. He was feeling dazed and ill, and his temperature was 103.2°. An hour earlier, feeling all right, he had left head quarters of the regiment, two miles back.

Phlebotomus fever had not previously been prevalent, nor were contacts from outside found. One or two subjects of malaria were on the strength. From dengue the condition is differentiated by the suffused eyes, absence of rash and of secondary rise in the temperature after a few days running normal. In paratyphoid the pyrexia seldom runs so high, and has not the characteristic third-day drop to normal. Severity of the rigor and fall of the temperature in a matter of hours distinguish it from malaria; enlargement of the spleen is also to be remembered.

Most cases were evacuated to hospital. Those remaining in the lines were kept together apart from the uninfected; they were given a purgative and sodium salicylate, phenacetin, or opium for the relief of the pyrexia and aching limbs. Subsequent debility was a marked feature

THE American Women's Zionist Organization announces that Mrs. Peter J. Schweitzer of Brooklyn has given £5,000 for the building and maintenance of a model eye hospital in Palestine. A medical unit has left for Jerusalem.

considering the shortness of the acute stage, but many managed to recover sufficiently to return to light duty after fourteen days.

CLINICAL NOTES ON PHLEBOTOMUS FEVER.

BY

CAPTAIN J. A. DELMEGE, R.A.M.C.,

AND

CAPTAIN C. S. STADDON, R.A.M.C.

PHLEBOTOMUS FEVER occurred in Macedonia as an epidemic which attacked certain units camped in the vicinity of some old ruined buildings.

The *Phlebotomus papatasi* fly was very numerous in the tents and dug-outs, and bites were inflicted both by day and night. Exposed parts were most affected—the

fur on the dorsum, but was clean at the tip and at the edges. The pulse was in many cases slow; rates of 55 and 50 were common, and in one case the rate fell to 40 during both of two attacks.

The temperature usually rose suddenly to 103° (105° was the highest noted), remained between 102° and 103° for about twenty-four to thirty-six hours, terminating, in the large majority of cases, by a critical fall, and remaining subnormal for three or four days.

The temperature charts showed three main types, depending on the fall and subsequent course of the temperature curve. In the accompanying charts the whole pyrexial period is not shown.

1. Curve showing a critical fall, or much more rarely a gradual one, on the second, third, or fourth day, and remaining subsequently subnormal or normal. (See Chart 1.)

2. Curve showing a critical fall to normal or subnormal, followed by a further rise, either immediate or after a day

CHART 1.

CHART 2.

CHART 3.

backs of the hands, the forearms, especially the flexor surfaces, the ankles, and the face. A small irritable papule was produced; in one case the papules were so numerous as to simulate a definite rash.

It was found impossible to make any accurate observations as to the fly's radius of action, but whether by actual flight, or more probably by conveyance on wagons and limbers, it was certainly not less than 300 yards, or more than 500.

The Incubation Period.—This varied from four to six days, and was marked by a feeling of malaise and irritability of temper.

The onset was almost invariably sudden, and was usually accompanied by slight shivering; no definite

or two, the temperature remaining up for one or two days. (See Charts 2 and 3.)

3. Curve showing a critical fall, followed by more than one post-critical rise of temperature occurring at irregular intervals. (See Charts 4 and 5.)

Course.—The prostration became more and more marked as the pyrexia continued, and by the time it subsided might have become very severe. The headache disappeared with the fall of temperature, but the backache and the pains in the limbs frequently persisted for several days afterwards; in several cases the pain only became marked after the fall in temperature had taken place. The slowness of the pulse often persisted for four or five days after the temperature fell. Appetite returned gradually,

CHART 4.

CHART 5.

rigors, however, were observed in any case. A slight degree of nasal catarrh, lasting for the first day or two of the fever, occurred in some.

Symptoms.—Severe headache, either frontal or post-orbital, was invariable; abdominal discomfort—not amounting to pain—backache (very marked in some cases), pains in the limbs, and anorexia usually accompanied it.

Signs.—The face was usually uniformly flushed, but though this flush was in no way typical, it did not in any way suggest the dark, flushed, bloated facies of relapsing fever. The conjunctivae were injected, but the amount of injection varied, being in some cases extremely marked and hardly noticeable in others. It bore no relation to the severity of the infection. The eyeballs were usually tender on palpation. The tongue showed a thick brownish

but convalescence was slow, and the patient remained debilitated for a week or ten days or even more.

The complications observed were:

Conjunctivitis.—This was quite severe in one case.

Epistaxis.—This occurred in several cases.

Sore Throat.—This, associated with faucial infection, was observed in several cases.

Vomiting.—This was quite marked in one case, and was not due apparently to any outside cause.

Reinfections were comparatively common. They were almost invariably milder; the temperature seldom rose above 100° F. (101.8° F. was the highest noted), and the rise lasted only one or at most two days. The symptoms and subsequent debility were also much less marked, and no complications were noted. No case of more than one reinfection was observed.

The treatment adopted presented no points of special interest. Tinct. opii mxx at the onset, repeated on the second and third nights and combined with magnesium sulphate 1 oz. daily, was found very efficacious. Aspirin relieved the headache and the pains. Easton's syrup was given during convalescence.

Conclusions.

The following would seem to be the chief clinical features in which the disease, as seen here, differed from the commonly circulated descriptions:

1. The occurrence of definite reinfections.
2. The frequency of post-critical rises of temperature.
3. The great variability in the amount of conjunctival injection.
4. The great preponderance of critical falls of temperature over those falling by lysis.

It is also an interesting fact that no cases were noted amongst the Cypriote muleteers camped in the affected area.

We should add that though it was impossible in a district like this definitely to exclude malarial infections amongst the cases studied, only those which from the clinical standpoint were undoubtedly phlebotomus fever were included in the series from which these conclusions have been drawn.

THE INVOLVEMENT OF THE EXTERNAL AND INTERNAL POPLITEAL NERVES IN LESIONS OF THE SCIATIC NERVE.

By T. E. HAMMOND, F.R.C.S.Eng.,

LATE SURGEON TO ALDER HAY MILITARY ORTHOPAEDIC HOSPITAL, LIVERPOOL.

DURING the South African war the external popliteal nerve was stated to be involved nine times as frequently as the internal popliteal nerve. In injuries of the sciatic nerve during the present war the proportion is stated to be three to one. Heffman believed it to be due to the smaller blood supply of the external popliteal; but, on the other hand, this is the smaller nerve. The fact that the internal lies more in line with the femoral vessels and that the external is the more superficial cannot account for the disproportion, as the nerves lie side by side, and bullets pass in all directions.

The external popliteal, corresponding to the musculospiral nerve in the arm, supplies muscles which act against gravity. The slightest lesion of the nerve is followed by paresis of the extensor muscles, which is always evident by foot-drop and steppage gait. Great clinical experience is not necessary to make a diagnosis, and, owing to the continual overstretching of the muscles, no improvement follows until proper treatment has been applied.

The internal popliteal, corresponding to the ulnar and median nerves in the arm, supplies the plantar flexors of the ankle, the small muscles of the foot, and sensory fibres to the skin of the heel and sole. The action of these muscles is aided by gravity. In complete division but slight deformity is usually present, and apart from inelasticity in the gait, slight inconvenience is caused; this is shown by the useful movement obtained in complete division of the sciatic after correction of the drop-foot by a suitable boot. In incomplete division slight pes cavus may be present with paresis of the flexor muscles and anaesthesia, trophic changes being usually absent. Voluntary contraction of the flexors produces plantar flexion of the ankle and toes. The paresis is often difficult to observe, unless a careful examination is made, full plantar flexion of the ankle and toes being possible by the action of gravity alone, if the extensors be relaxed. It should be sought for with the patient lying prone and the knee flexed to a right angle, plantar flexion now taking place against the action of gravity. The skin of the sole and heel is not very sensitive, and to excite epicritic sensation in the normal sole slight pressure of the cotton-wool may be necessary. The internal saphenous and the popliteal position of the external saphenous encroach on

the sole of the foot and many of the ligaments are supplied by the external popliteal, and as in an incomplete lesion deep pressure sensation is often retained, the greatest care in applying the cotton-wool test is necessary.

In the case of an incomplete lesion of the internal popliteal associated with a complete or incomplete lesion of the external popliteal, the flexor muscles contract with the aid of gravity, and, as they have not to overcome the normal tone of the extensors, their action may appear to be as great as usual.

Careful examination by a competent observer is necessary for the diagnosis of some of these incomplete lesions. The foot from the time of the injury is placed by the action of gravity in the position of plantar flexion, this relaxes the affected muscles and helps their recovery, even if no treatment be applied.

In lesions of the sciatic nerve admitted to Alder Hey from other hospitals, the external popliteal was affected three times as often as the internal. The greater number of the latter were admitted for the painful neuritic condition, or for the combined lesion with foot-drop.

One hundred cases, admitted direct from France, in which the wound was in the upper two-thirds of the thigh, and there was a possibility of sciatic involvement, were carefully examined by me. The sciatic nerve was involved in 22.

In 4 the external and internal portions were completely involved.

In 3 the external was completely and the internal incompletely involved.

In 2 the internal was completely and the external incompletely involved.

In 9 the external and internal were both incompletely involved.

In 3 the external was alone involved.

In 1 the internal was alone involved.

The external popliteal was thus involved in 21 and the internal in 19 cases. In some of the latter diagnosis was only possible after a most careful examination, and in most cases the associated foot-drop alone caused inconvenience; except in the painful neuritic forms, there was a marked tendency for improvement to occur in the incomplete lesions. Incomplete lesions of the external popliteal did not show the same tendency to recover, and with the slightest paresis diagnosis was always evident owing to the inability to maintain dorsiflexion.

Conclusions.

It may therefore be stated that for diagnosis of incomplete lesions of the internal popliteal nerve a most careful examination is necessary, especially if a lesion of the external popliteal be present. In addition, the muscles are naturally placed in the position of relaxation, and recovery follows in many cases without a diagnosis or any special treatment. Incomplete lesions of the external popliteal are always associated with foot-drop, and, as the affected muscles are overstretched, no improvement follows until a diagnosis has been made and appropriate treatment instituted.

I cannot but think that the majority of lesions of the internal popliteal are never diagnosed, while lesions of the external popliteal are scarcely ever missed. During the examination of certain cases which could not pass the necessary tests at a command dépôt thirty-six nerve lesions were discovered by me, in spite of the fact that all cases should have been fit for general service four months after admission; thirty-five were previously undiagnosed lesions of the median and ulnar nerves, while only one was a lesion of the musculospiral, and this had been operated upon. Lesions of the median and ulnar nerves do not usually give rise to a deformity of a degree comparable to that present in musculospiral lesions. It therefore seems that even in the arm nerve lesions are more likely to be missed by inexperienced observers if marked deformity be absent; this must apply all the more to the leg, where special function of the toes is not required.

At a meeting of the Société de Biologie on March 23rd Professor Richet read a paper on the mechanism of death by haemorrhage. He stated that in a dog bled to 4 per cent. of its weight, respiration was profoundly affected by the position of the head. If it were lowered the animal breathed regularly; when it was raised respiration became apnoeic. He concludes that death by haemorrhage is due to cerebral anaemia.

THE EPIDEMIOLOGY OF MENINGOCOCCAL MENINGITIS, OR CEREBRO-SPINAL FEVER.

By A. M. N. PRINGLE, M.B., C.M.,
M.O.H. IPSWICH.

THE prevalence of cerebro-spinal fever is essentially seasonal, as is well illustrated by the fact that in Ipswich, during the three years 1915-1917, 26 cases occurred in the March quarter, 33 in the June quarter, 2 in the September, and 2 in the December quarter. The maximum prevalence of the disease was in the month of March, closely followed by April. The next in order were the months of May, February, and June, but the degree of prevalence in these three months may be judged from the fact that the total number of cases for the three months was equal only to that of the month of March. After June the cases have been sporadic; the only month in which no cases have occurred has been July.

The position, therefore, is that the disease has never been entirely absent from Ipswich during the last three years, but has been most prevalent in February, March, April, May, and June, particularly in March and April. This seasonal prevalence has been characteristic of each of the three years.

Consideration of these facts would appear to establish a *prima facie* case for the association of the disease with some condition, or conditions, common to the whole year, but most in evidence in the winter and spring.

Without entering into details, we may assume that most would agree that an organism found in one part of the body, morphologically, culturally, and serologically identical with an organism inhabiting another part of the human host was one and the same organism. We are therefore justified in the assumption that a nasopharyngeal coccus and the meningococcus, which are morphologically, culturally, and serologically identical, are one and the same organism. The fact that the meningococcus in the cerebro-spinal system produces the phenomena of meningococcal meningitis, and that in the nasopharynx it produces no obvious symptoms, is quite consistent with this conclusion.

A large number of demonstrations go to prove that the nasopharynx of an individual suffering from meningococcal meningitis contains the meningococcus in the early stages of the disease. Failures to demonstrate the meningococcus in the nasopharynx of cases of meningococcal meningitis may be due to many causes, such as the extreme delicacy of the organism, faulty swabbing, possibly the exhibition of an anaesthetic before the swab is taken, the taking of swabs too late in the disease, and so on.

The practical epidemiological point is that there is sufficient evidence to justify the opinion that in every case of meningococcal meningitis the nasopharyngeal precedes the meningococcal infection. If this view be accepted, then the spread of the disease is due to the transference of the meningococcus from one nasopharynx to another.

We may now inquire what evidence exists indicating that the meningococcus is spread from person to person. In this relation I quote the figures of a recent report by the Local Government Board, which epitomizes the work done in this matter by the Board's bacteriologists. They found that amongst 1,881 persons from many different sources and places who had not been in contact with cases of cerebro-spinal fever, no less than 13.5 per cent. harboured in the nasopharynx an organism which was morphologically and culturally identical with the meningococcus, and in the opinion of the Board's bacteriologists was, in fact, the meningococcus. If this statement be correct, even if the proportion given is greatly overstated, it affords definite evidence of a widespread nasopharyngeal meningococcal infection. The number of persons infected in an infected area would, on this basis, in a town of the size of Ipswich, in any one year, be very large, each being capable of transmitting the infection to others.

A normal healthy nasopharynx will rid itself of the meningococcus without treatment, or in spite of it, on the average, in something under a fortnight. An unhealthy nasopharynx, with adenoids, etc., can retain the infection for a longer period. Some individuals retain the infection for prolonged periods and become true carriers. I have known one case out of a limited number which remained

infected for over six weeks. Such persons will serve to assist in maintaining the meningococcus in a locality and will help to bridge over the summer and autumn intervals. Naturally, those in this group will be relatively few, so that the numbers infected by them will be few in relation to the total population. Nevertheless, they will assist in maintaining the reservoir.

We are now in a position to go back to the seasonal nature of meningococcal meningitis. Nasopharyngeal infections of all sorts are spread from person to person in the acts of coughing and sneezing, the immediate atmosphere being impregnated with spray or droplets, containing members of the nasopharyngeal flora. Therefore, all nasopharyngeal infections will be most readily spread during the seasons of the year when coughs and colds and other nasopharyngeal and respiratory infections are most prevalent. The spread of infection will be assisted by the closer crowding of the population during these periods of the year and by the closing up of ventilation and the complete ignorance and indifference of the public as to the mode of spread of this group of catarrhal infections.

We should, therefore, expect that meningococcal meningitis, secondary to nasopharyngeal infection, would be most prevalent in February, March, April, and May, which is precisely what does occur, as evidenced by the sudden appearance of cases of the disease in these months.

In my opinion the rise in meningococcal meningitis coincides with an increase in the density of the nasopharyngeal infection, whilst the summer and autumn fall coincides with a corresponding drop. We thus get a vicious circle produced by (1) a rise in the usual winter coughs and colds, a proportion of the sufferers harbouring the meningococcus; (2) a number of people are infected by these, the number varying with the opportunities of infection; (3) these in turn cough on the infection, and thus with an increase of catarrhal infections a constantly increasing number of persons become infected with the nasopharyngeal infection; (4) when the finer weather comes on, coughs and colds diminish rapidly, and so does the meningococcal nasopharyngeal infection.

The question may now be asked, granting all this, Why are there not more cases of meningococcal meningitis? My answer to this is that the invasion of the meninges by the meningococcus is an accident dependent on conditions as yet undetermined. If this view is correct, it is merely a mathematical proposition that the greater the number of individuals involved, granting the possibility of the accident, the greater will be the number of accidents. I believe that the existing evidence tends to show that the height of the meningococcal epidemic corresponds to the greatest density of the nasopharyngeal epidemic and that the sporadic cases occurring during the other parts of the year merely indicate the existence of a reservoir of nasopharyngeal meningococcal infection.

If these views are correct, then the present mode of dealing with a few positive contacts of a few cases of meningococcal meningitis is futile.

In support of this view of the epidemiology of the disease is the quite marked independence of individual cases. True, on occasion, more than one member of the same family may be attacked. Thus I have seen three cases in one family and two in another. Nevertheless, the general fact is that the cases are single and independent and occur amongst individuals who have no connexion of any kind with one another. This, in my opinion, is strong evidence of a widespread generalized infection.

A FATAL CASE OF PARATYPHOID B SIMULATING TYPHUS FEVER.

BY

P. S. HICHENS, M.D., AND E. J. BOOME, M.B.,
F.R.C.P. D.P.H.,
TEMP. LIEUT.-COLONEL CAPTAIN R.A.M.C.(T.F.).
R.A.M.C.(T.F.).

THE following fatal case of paratyphoid fever due to the *Bacillus paratyphosus* B seems to be worth noting, not only from the extreme severity of the lesions found *post mortem*, but also from the clinical course of the disease.

On admission to this unit the patient presented a clinical appearance almost indistinguishable from an advanced stage of typhus fever. He was in a state of

low muttering delirium with carphology, coma-vigil, and retention of urine; there was a faint purple petechial and macular eruption on the chest and abdomen. Had we not had the advantage of skilled bacteriologists to examine the patient both before admission to this unit, and also while here, the condition would almost certainly have been diagnosed as an advanced stage of typhus fever. Owing to our situation at the front, it has been impossible for us to search the literature and ascertain whether many other such cases have been already recorded. As far as we have been able to learn the number of severely toxic cases of paratyphoid is very small.

The kidney lesions in this case were remarkable, and Hurst in his book, *Medical Diseases of the War*, seems to describe a somewhat analogous case suffering from paratyphoid A, in which death occurred from suppurative nephritis in the fifth week. Death occurred in this case in the third week from what might be called "a pyaemic condition," and in all the abscesses the *Bacillus paratyphosus B* was found.

Captain Lindsay of the 13th Mobile Laboratory discovered the bacillus before the case was admitted to this hospital, and we are grateful to Captain J. Cruickshank, Officer Commanding 18th Mobile Laboratory, for further bacteriological investigations and the help he gave at the necropsy. We are indebted also to Captain A. M. Davie, R.A.M.C.T., for notes on the patient at the onset of his disease in the line, and to Captain Gray, R.A.M.C., for some of the earlier clinical notes.

Condition of Patient in the Line.—The patient had had two doses of antityphoid vaccine in December, 1915, and two doses of the triple vaccine (T.A.B.) in June, 1917. He had served nine months in France, and had reported sick at odd times before with very minor ailments. On September 17th, 1917, when the battalion was in the line, he complained of pains in the stomach and diarrhoea of sudden onset. Next day he complained of pains in the head and legs, with shivering; temperature 101.2°; diarrhoea better. He was sent by the regimental M.O. to the field ambulance as P.U.O., and was detained there for the night. On September 19th he was evacuated to a clearing station, complaining of pains in the head and across the abdomen, with pain also in the muscles of the thigh and calf. On September 20th there was pain and tenderness in the epigastrio region, with cramps in the hands and legs, vomiting, rigors, and cough. On September 24th abdominal pain was complained of, the lower abdomen being tender, but not rigid. The patient complained of retention of urine, but passed a small quantity after suprapubic fomentation. From September 25th to 29th the condition was much the same; the urine passed in twenty-four hours varied between 4 and 12 oz. On September 29th *B. paratyphosus B* was found in the blood on culture. The spleen was palpable and the urine smoky. He was transferred to the infectious casualty clearing station.

Condition on Admission.—The patient was semi-comatose, with dusky and livid face. There was retention of urine and the bowels were confined. Epistaxis occurred. After a while there was low muttering delirium and carphology. The abdomen was slightly distended and tender, the spleen readily palpable; there were no typical rose spots, but on the chest a fine petechial eruption with subcuticular mottling in the axillae. Next day the patient was much worse, wildly delirious, and trying to get out of bed. Signs of consolidation were found in the left lung and at the base of the right lung. A simple enema was given with satisfactory result. Ten ounces of bloody urine were drawn off by catheter. The patient died at 5.45 a.m. on September 31st.

Post-mortem Examination.

On the abdomen and front of chest there were a few pale petechial spots.

Left Lung: Adherent all over (old adhesions). Large haemorrhagic infarction in lower lobe; area of infarction with pneumonia in upper lobe. *Right Lung:* Free from adhesions; lower lobe completely consolidated; early grey hepatization, with red hepatization of contiguous portions of other lobes. There was inflammatory exudate between the lobes.

Ileum congested along whole length, with acute inflammation of mesentery in this area; glands enlarged, congested, and haemorrhagic; Peyer's patches along last three feet of ileum swollen and congested; no ulceration. Large intestine contained fluid faeces; diffuse inflammatory changes along caecum and ascending colon.

Surface of left kidney studded with yellowish-white nodules and in places definite abscesses with fluid pus; on section kidney riddled with abscesses. Similar septic condition of right kidney.

The liver showed cloudy swelling; gall bladder markedly distended. Spleen enlarged and congested; haemorrhagic spots on section. The bladder showed well-marked purulent cystitis. Brain and medulla: Some excess of fluid, but no meningitis.

B. paratyphosus B was grown from urine, kidney abscesses, bladder, and spleen.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

PREVENTION OF NERVE BULBS IN STUMPS.

PAINFUL bulbs on the ends of nerves following amputation are so frequent and troublesome as to cause a very protracted convalescence in a large number of cases. In an article in the *BRITISH MEDICAL JOURNAL* of August 25th, 1917, I described a method of dealing with nerves which experience has further shown to be valuable in preventing these neuromas.

Recently I had the advantage of seeing a median nerve which had been treated in this way four months previously together with an ulnar nerve which at the amputation had been severed in the ordinary way. The median end was the shape of a pointed pencil, and the ulnar nerve had a large and tender bulb.

It would appear that when a nerve is severed in amputation the axis cylinders grow out in search, as it were, of those of the other severed end. These nerve elements from the central end multiply, enlarge, and get involved in and surrounded by fibrous tissue, which on contracting squeezes and renders tender and painful the sensitive nervous tissue involved in the mass. A bulb may exist and not be painful or tender until this contraction takes place.

My experience tends to show that if the sheath of a nerve is cut and stripped back along its trunk with a piece of gauze between the finger and thumb for about half an inch in the form of a cuff, and then brought forward and tied after the denuded trunk has been severed, the sheath acts as a limiting resisting membrane, and this protrusion of axis cylinders is prevented.

COINCIDENT INFECTIONS OF GONORRHOEA AND SYPHILIS.

FROM 5 to 10 per cent. of all cases of gonorrhoea subsequently develop syphilis. The infections are acquired simultaneously or within a short period. In an experience during the last twelve months of over 200 cases of double infections I have never seen complications or retardation of cure caused by either mercurial or arsenical preparations, as suggested by Captain Lumb (*BRITISH MEDICAL JOURNAL*, March 9th, p. 285). The cases were treated with injections of novarsenobillon, either intravenously or subcutaneously, and 1 grain of mercurial cream weekly. Smears for gonococci were taken on admission, and afterwards weekly smears, the first thing in the morning. If the smear was negative and the patient dry for seven days, a urine test was done after prostatic massage. If this test was negative the case was considered cured.

Patients in the syphilis wards gave negative smears sooner than those in the gonorrhoea wards, due, as I concluded, to their having to rest more, owing to their injections, and perhaps a greater incentive to get rid of a loathsome combination by inducing them to irrigate thoroughly. Venereal hospitals are a refuge for many slackers and shirkers. Among these 200 cases two of epididymitis occurred during treatment, and another about a month after the completion of antisyphilitic treatment following the passage of a bongie. No cases of prostatitis occurred. The treatment for gonorrhoea was irrigation of the bladder with potassium permanganate and prostatic massage occasionally. No drugs were given, and vaccines only in cases of rheumatism. The patients, except in rare instances, were cured of gonorrhoea before the course of antisyphilitic treatment was completed.

The urethral discharge is sometimes increased following an injection of neosalvarsan, especially in early secondary syphilis with wide generalization of the spirochaete—the class of case in which a rise of temperature and malaise follow a first injection. Any depressing cause will increase the urethral discharge temporarily. In early primary syphilis reactions seldom occur.

A small proportion of cases are either lamed by intramuscular injections of neosalvarsan, or have so much pain as to make the method unsuitable in private practice. The deep subcutaneous method causes less pain and

certainly much less stiffness. It is suitable for all but very thin men. The novarsenobillon is dissolved in a few drops of distilled water, croc-camph. added up to 2 c.cm., and injected immediately. The needle is inserted vertically to the skin over the upper and outer gluteal region to a depth of about three-quarters of an inch. I do not find stovaine solution any help. Only neosalvarsan or its equivalents, neokharsivan, novarsenobillon, or novarsenobenzol, can be used for subcutaneous injections.

JOHN A. WATT,
Captain R.A.M.C.T.

Warlingham Military Hospital.

APPENDICITIS IN A FEMORAL HERNIA.

MRS. D., aged 43, had a lump in her right groin for ten years, and had had attacks of "inflammation" in it about twice a year, usually brought on by extra work. The attacks lasted about a week, during which the lump would become larger and painful, and she had pain in the lower part of the belly. The history as to vomiting and constipation was uncertain.

On January 16th, 1918, an attack commenced, and as she gradually became worse her doctor advised her admission to hospital (January 23rd, 1918). The lump was a femoral hernia, large, tense, and tender; her bowels had opened after medicine two days before, and there was no vomiting; pulse 100, temperature 99°.

The sac was found to be tense and full of clear fluid; at the bottom was what was thought to be either a Richter's hernia, or possibly the appendix. After the constriction had been nicked and enlarged four inches of appendix was easily pulled down, the terminal inch being doubled on itself; a cuff was turned up and the four inches of appendix crushed and removed. As the woman was fat and had chronic bronchitis, it was not considered advisable to prolong the operation by removing the rest of the appendix flush with the caecum.

The appendix in its terminal two inches and its mesentery were considerably enlarged and thickened; much of the thickening was not recent; it appeared as if it would have perforated at the bend referred to. Recovery was uneventful.

Rhymney Cottage Hospital.

REPLACEMENT AND RESTORATION OF FUNCTION OF THE UTERUS AFTER PROLONGED INVERSION.

ON September 30th, 1917, a Gilbertese married woman, aged about 25, was admitted to Betio Central Hospital, Tarawa, suffering from complete inversion of the uterus. The inversion took place at the birth of her youngest child, now aged 2½ years, and had been present ever since. There were no symptoms, there had never been any haemorrhage, and the only thing that the patient complained of was the presence of the tumour.

Reduction after cleansing was attempted in vain.

The part was washed daily with sanitas lotion, 1 in 100, and two weeks later I was able to reduce the inversion with very little pressure and replace the uterus. A ring pessary and a cotton-wool tampon were inserted. The tampon was removed daily, the patient was douched, and a fresh tampon introduced.

In about two weeks she had a little blood on the tampon one morning. Four weeks later menstruation occurred normally.

The case may be interesting to practitioners because of the apparent rapid restoration of function after such a long period of "rest."

ERRANT RABBIT BONES.

ON two occasions I have seen at *post-mortem* examination rabbit rib bones on their way through the small intestine to the peritoneal cavity. In one case there were two of these bones passing through, and in the other only one. They had had nothing to do with the cause of death.

SPIROCHAETOSIS ICTEROHAEMORRHAGICA.

AT a meeting of the Section of Medicine of the Royal Society of Medicine held on March 26th, Surg.-General H. D. ROLLESTON, R.N., being in the chair, Colonel Sir BERTRAND DAWSON, K.C.V.O., R.A.M.C., gave a lecture on *spirochaetosis icterohaemorrhagica*, exhibiting pictures on the epidiascope illustrating the cases and the pathological conditions. (See paper by Dawson, Hume, and Bedson, *BRITISH MEDICAL JOURNAL*, September 15th, 1917.) After discussing the etiology and symptoms Sir Bertrand Dawson showed notes of cases illustrating various types of the disease, and demonstrating how the brunt of the morbid process did not always fall on the same organs. He considered that the jaundice was caused either (1) by obstruction to the outlet of the common duct in the cases where there was inflammation and swelling of the duodenum and papilla of Vater and no changes within the liver except bile stasis, or (2) by interference with the drainage of bile within the liver, in cases where there was disorganization of the lobules with damage to the cells and intrahepatic ducts. Where there were no definite changes in the liver and no swelling of the duodenum, jaundice was absent. Repeated examinations had shown that jaundice was not due to over-production of bile. There had never been any evidence of blood destruction, and in two cases in which it was tested the blood fragility was normal. Comparing this disease with acute yellow atrophy, the speaker considered that what was styled in the *post-mortem* room "acute yellow atrophy" was the fullest anatomical expression of a destructive process, of which there were several grades, and which might be caused by several agencies, the *Spirochaeta icterohaemorrhagiae* amongst them. The *spirochaete* was found with difficulty in man, but was abundantly present in the guinea-pig, in the blood of the jaundiced animal, in the liver, and in the kidneys and suprarenals. *Spirochaetes* were excreted in the urine, faeces, and bile. In the diagnosis of *spirochaetosis icterohaemorrhagica* the presence of the typical *spirochaete* taken in conjunction with the clinical manifestations was strong evidence on which a positive conclusion was warranted.

In the course of the discussion Surgeon-General Sir DAVID BRUCE said that no *spirochaetes* had been found in cases of jaundice in South Africa. There was no proof that *spirochaetes* had been found in trench fever. None were present if precautions were taken in collecting the urine. He thought that there was not yet sufficient proof to warrant the assumption that the infection in *spirochaetosis icterohaemorrhagica* took place by the mouth. The same thing had been said of malaria before it was proved otherwise. Infection might occur through the skin.

Surgeon-General ROLLESTON said that probably many cases of "Weil's disease" were *spirochaetal* jaundice, whilst the splenic enlargement in others might be evidence of enteric jaundice.

HOSPITALS FOR ADVANCED PULMONARY TUBERCULOSIS.

AT a meeting of the Tuberculosis Society on March 25th, at the House of the Royal Society of Medicine, a discussion took place on the need for hospitals for advanced cases of pulmonary consumption.

Dr. HALLIDAY SUTHERLAND, the President, commenting on the recent rise of 12 per cent. in the death-rate from pulmonary tuberculosis in England and Wales, suggested that active measures against tuberculosis were likely to be followed by an immediate rise in the death-rate, because when the services of experts were generally available many deaths now wrongly attributed to bronchitis or to chronic pneumonia would then be ascribed to their real cause—tuberculosis. But there was no adequate provision throughout the country for the treatment of advanced cases. The Departmental Committee on Tuberculosis (1912) recommended as a minimum standard that the combined number of sanatorium and hospital beds should be one bed to every 2,500 of population. He estimated that of all new

cases of pulmonary tuberculosis coming to tuberculosis dispensaries 50 per cent. could be treated at dispensaries, at open-air schools, or at home; 30 per cent. required sanatorium treatment for an average period of six months, and of these latter one-third required a year's subsequent treatment at a farm colony; 20 per cent. would be in the advanced stages; of these, half were living in small overcrowded houses, where the chance of infecting others was very great and comforts were very few; and for these patients tuberculosis hospitals were required. Clinical experience suggested that for every two who died of pulmonary tuberculosis there were three patients needing sanatorium treatment. Applying that formula to Scotland, there were, on a moderate estimate, 7,936 patients in 1915 requiring sanatorium treatment. But actually there were only 2,365 beds available for all cases, while there were 2,645 advanced cases requiring hospital treatment. There was one bed for every 2,010 people, and in 1917 there was one bed for every 1,900 people. In England and Wales there were 41,676 deaths from pulmonary tuberculosis during 1915. In June, 1916, there were 11,893 beds in England, or one bed per 2,973 people. Including Wales, there were 12,523 beds. He estimated that in the two countries there were 62,514 cases requiring sanatorium treatment. But there were 20,838 advanced cases requiring hospital treatment. England needed 50,975 beds, or one bed per 693 of population—more than four times the number available in 1915. Of new beds, over 30,000 were needed in sanatoriums, over 10,000 in farm colonies, and over 9,000 in tuberculosis hospitals. Outside the Poor Law he did not know of more than 600 beds for advanced cases in England and Wales, hence sanatoriums for the most part were filled with advanced cases. The truth of the matter was not the recent unfortunate verdict of the Medical Society of London that sanatoriums had failed, but that sanatoriums so far had never had a chance. A tuberculosis hospital of 20 beds should be created in the vicinity of every tuberculosis dispensary. If that were done to-day, 7,420 beds would be available for advanced cases within easy access of their homes. In addition to hopeless cases these hospitals would admit some patients for observation and others for special treatment. When suitable treatment was offered the people would take advantage of it. Compulsion would be unnecessary, and, indeed, where it had been tried, as in New York, the result was a failure.

Mr. HERBERT WOOLCOMBE (Charity Organization Society) said that the whole subject was one of great urgency, and was about to be considered by the National Association for the Prevention of Consumption.

Dr. F. R. WALTERS (Surrey) thought the President had under-estimated the number of advanced cases, if they were agreed on their definition of an advanced case. Cases could be divided into ambulant and febrile, and many of the febrile cases required hospital treatment.

Sir ROBERT PHILIP said that care must be taken in the definition of an advanced case. There was a stage in the illness beyond which the case was hopeless, and for such patients these hospitals were primarily intended. If any other definition were accepted the ground which should be covered by other institutions would be encroached upon. As regards the failure or success of sanatorium treatment, that was a subject on which members of such a society should be able to express an opinion.

Dr. A. J. SHINNIE (Westminster) said that the Westminster guardians had a special hospital at Hendon, and there was no difficulty in inducing patients to go to it, although it was difficult to persuade them to go to an ordinary Poor Law infirmary.

Dr. J. A. RAEURN (Battersea) thought that the President had over-estimated the number of advanced cases for whom hospital treatment was required.

Dr. SUTHERLAND, in his reply, said that the estimates he had given were intended to serve as a basis for discussion.

The following motion was then passed unanimously:

That the Tuberculosis Society is of opinion that no adequate provision exists for the treatment of advanced cases of tuberculosis; that a tuberculosis hospital should be created in relation to every tuberculosis dispensary; that such hospitals should be under the medical control of the tuberculosis officers; and that the Society will welcome any effort on the part of the National Association to bring such hospitals into being.

Reviews.

EDINBURGH SURGERY BEFORE LISTER.

COMING so soon after Sir Rickman Godlee's life of Lord Lister, Mr. MILES's pleasantly written account of *The Edinburgh School of Surgery before Lister*¹ is most appropriately timed. Mr. Miles evidently enjoyed his task, and carries the reader easily from the first pages with the weird spelling of the Barber-Surgeons' petition in the sixteenth century to Lister's appreciation of his father-in-law and immediate predecessor, James Syme. The first deacon of the barber-surgeons was Gilbert Prymross, chirurgion to James VI and ancestor of Lord Rosebery, Hon. F.R.C.S. Eng. and Ed. This guild, while not advancing surgery directly, created opportunities for practical anatomy by obtaining from the town council in 1505 the grant of "ano condemnit man after he be deid, to make anatomie of," though there is no evidence of a regular course of instruction in this subject till the end of the seventeenth century. The surgeons and barbers parted company in 1722, the barbers lingering on till 1892. The period of the Monros began in 1720 with the appointment to the chair of anatomy at the early age of 22 of Alexander, whose just fame has obscured his father's claim to grateful memory for his efforts in stimulating the authorities to organize a complete system of medical education within the university and the institution of the Faculty of Medicine in 1725. The Royal Infirmary, opened in 1741, arose out of the amalgamation of the Physicians' Hospital (1729) with the Surgeons' Hospital (1736), and for years contained the only public bath in the city. During the first half of the eighteenth century the surgeons were not specialists, and during this period of the practitioner surgeons the only names that stand out are those of John Bennet and Alexander Wood. Sketches of them are given, interesting rather on account of their eccentric and convivial characters than for their professional and original eminence. The rise of the Edinburgh school of surgery is traced from its father, Benjamin Bell, who was an ancestor of Joseph Bell, the last of his race and the reputed prototype of Sherlock Holmes, and is followed by chapters on the systematic and clinical professorships which contain many attractive biographies. The lives of Lister and Syme, with the story of their friendship, rivalry, quarrel, and reconciliation, are especially interesting. In conclusion, though what is easy to read is rarely so easily written, we may express the hope that when the physicians of this great school are described, as they should be, in a companion volume in this series, the same success may be attained.

OPERATION AND AFTER.

MR. W. I. DE C. WHEELER's little handbook of *Operative Surgery*² has quickly reached its third edition; the best evidence that it meets a want. Probably, as Sir Alfred Keogh says in his foreword, a great number of young men called upon to take the responsibility of major operations without much experience, appreciate the possession of a small book that just fills a corner in the kitbag. As a matter of fact Mr. Wheeler has tried to hit two birds with one shot: to offer guidance to the senior student in his first course in operative surgery on the cadaver, and at the same time to provide an easy reference aid for the young surgeon at the front. Considered academically, it is to be feared that the author has but winged his birds; there is not enough "spread" in 364 pages. In these surgical centres near the front where the energetic junior staff fill in their spare time with operative surgery classes—and there are such—this is just the book to have.

A great merit of Mr. ALAN H. TODD's book on *Surgical After-Treatment*³ now in its second edition, is that it is cheap, and thus accessible to the house-surgeons, students,

¹ *The Edinburgh School of Surgery before Lister*. By Alexander Miles, Surgeon to the Royal Infirmary, Edinburgh. The Edinburgh Medical Series. London: A. and C. Black. 1918. (Pp. 220; 8 page illustrations. 5s.)

² *A Handbook of Operative Surgery*. By William Ireland de C. Wheeler, Lieut.-Colonel R.A.M.C. Third edition. London: Baillière, Tindall, and Cox. 1918. (Cr. 8vo, pp. 364; 226 figures. 10s 6d. net.)

³ *A Practical Handbook of Surgical After-Treatment*. By Alan H. Todd, M.S., F.R.C.S. London: Edward Arnold. 1917. (Cr. 8vo, pp. 236; 36 figures. 4s. 6d. net.)

and nurses for whom it is primarily intended. It is indexed, and the information it contains is therefore available at the moment it is wanted. Probably the author will modify some of the views he expresses when he is a little further away from a hospital, but with the exception of some dicta as to secondary haemorrhage on p. 54—which, to say the least, are obscure in their orthodoxy—the advice given is generally safe. If every patient who has an injection of salvarsan is to wear an anterior splint for twenty-four hours, the venereal clinics will not be popular. It is a useful little book.

BIOLOGICAL ASPECTS OF WARFARE.

FROM the biological aspect the combative instinct is a universal and normal attribute, and its evolution chiefly depends on three factors—the reproductive instinct, the search for animal food, and intertribal warfare. Cannibalism makes for ferocity, and man, the arch-slaughterer, according to Dr. CAMPBELL in his book on *The Biological Aspects of Warfare*,⁴ shares with the tiger the two opposed dispositions of combative destruction for his victims and tender altruism for his offspring. But cruelty, the basest of all vices, is not seen among the subhuman animals—even a cat playing with a mouse—who are unconscious of the sufferings of others; to speak of a cruel man as "brutal" is therefore unjust to the brutes. Dr. Campbell's argument is that when the arboreal life of the forest was given up, the conditions entailed by a hunting career brought about the evolution of the pre-human ape into man, and the resulting intertribal battles further stimulated his mental powers and led to the survival of the fittest. But here Dr. Campbell draws a contrast with modern wars, in which the losses on the two sides are approximately the same and the best physical types more or less equally eliminated, while the individual is benefited to some extent by education and discipline, though as a whole the influence is dysgenic by promoting inferior physical types. He follows Herbert Spencer in regarding the exercise of might as legitimate within certain checks or limits which increase with the growth of commercial life. But though it might have been anticipated that these restraints to might-sanction would by now have spread widely, the present war has witnessed the abandonment of moral restraint and reversion to the primal sanction of might by one group of belligerents. The influence of war for good, in stimulating a nation to enormous efforts of production, must be admitted; but it is much to be desired that a similar outburst of energy to wage war on the hygienic and economic evils in our midst in times of peace could also be evoked.

Struggles and powerful stimuli are essential for development, but how in the future, without recourse to war, the degenerating effects of luxury can be counteracted is a great social problem. As means to prevent war, attention is drawn to democratic government and all-round free trade; the latter may now seem the dream of a visionary, but dreams have come true. Dr. Campbell is a stimulating writer, and as his essays are never dull the two short papers on the factors determining man's evolution from the ape and on claustrophobia, bound up in this volume, may be recommended to the usual thoughtful reader.

TROPICAL LABORATORY WORK.

THE scope of the fourth edition of *Laboratory Studies in Tropical Medicine*⁵ by Drs. DANIELS and NEWHAM is explained in the preface. The authors have tried as far as possible to bring the book up to date, and to incorporate any new methods which have been proved to be sound and of general utility. They point out that the war has brought into contact with problems of tropical medicine many who had not previously given any attention to them; it is hoped that the book will help to tide some of those over their difficulties. The unfortunate thing about so many of these new workers is that they will not take the trouble to consult the literature, and in many instances rush into print with what appears to them to be something

entirely new, whereas it probably saw the light of day a good many years ago. It is sincerely to be hoped that any in this category will read the above book and inwardly digest it. A criticism which must be made is that the part of the book dealing with protozoa in the faeces is not full enough, more especially in view of the great attention lately given to this branch by so many workers. No mention is made, for example, of Wenyon and O'Connor's *E. nana*, nor of the cyst of the small species of *E. histolytica*, so difficult to tell from the cyst of the former. The occurrence of coccidia in human faeces might also have been dealt with in more detail. However, space must be considered, especially in these days, and the authors have probably hesitated to expand the work. The book is a very useful one, and will help these for whom it is intended in every way.

NOTES ON BOOKS.

DR. E. W. G. MASTERMAN, in his little book *The Deliverance of Jerusalem*,⁶ shows the intimate acquaintance with the city to be expected of one who has lived there on and off for twenty years, and a knowledge of the topography and archaeology of the holy land which becomes the Honorary General Secretary of the Palestine Exploration Fund in that country. His description of the plain of Philistia and its coastal cities, of the inland mountains, among which Jerusalem stands some 2,450 feet above the sea, and of the deep valley of the Jordan, renders the military operations easy of comprehension. As to the future of Palestine he writes cautiously. Syrian Moslems formed about three-fourths of the relatively small population before the war. The immediate needs are a settled and just government, an efficient sanitary service, and capital to restore agricultural prosperity and at the same time to check malaria, by which many districts are scourged. The book contains a map and a number of excellent illustrations.

The Belgian Hospital at La Panne is well known to all the world. There is perhaps no better method for those at home to get an idea of the work at a forward operating centre, of the opportunities for scientific investigation of war problems, or of the good use to which charitable funds may be put, than perusal of the first fasciculus of the *Publications by the Staff of the Ambulance de "L'Océan"* under the editorship of the director Dr. DEPAGE. The first 65 pages, by the editor, are devoted to a description of the hospital and all its internal arrangements; not the least interesting part being the account of the "Institut 'Marie Depage'" or group of buildings devoted to research. Dr. Debaisieux gives a good summary of the treatment of wounds, particularly by the Carrel method, and this is followed by an article on secondary suture of wounds. Cranio-cephalic injuries are dealt with by Dr. Janssen from the points of view both of morbid anatomy and clinical practice. Dr. Rubbrecht follows with a contribution on the treatment of fractures of the jaws; Dr. Dustin with one upon the neurological service. The remaining papers are the outcome of research work done in the laboratories, the results of which have already been incorporated in the daily practice of all the allied medical services.

The second edition of JELLIFFE and WHITE's *Diseases of the Nervous System*⁷ aims at providing for the advanced student and for the practitioner of medicine a textbook of neurology and psychiatry. It is divided into three parts: The first deals with the physico-chemical systems of the body—namely, the vegetative or visceral system and the "endocrinopathies" or disorders due to disturbances of the ductless glands. The second part is given to sensorimotor neurology, or disorders of the nervous system generally. Part three, some two hundred pages in length, deals with disorders of the psychical or symbolio systems—neuroses, psychoneuroses, and psychoses—ending up with an account of "characterological defect groups." This extremely up-to-date textbook is full of facts and figures and is well illustrated. It is not food for babes, and should appeal mainly to the expert in nervous disorders.

⁴ *The Deliverance of Jerusalem*. By E. W. G. Masterman, M.D., F.R.C.S. London: Hodder and Stoughton. 1918. (Demy 8vo, pp. 51, 1s. net.)

⁵ *Ambulance de "L'Océan" La Panne*. Fasc. I. Paris: Masson et Cie, London: H. K. Lewis and Co., Ltd. 1918. (Roy. 8vo, pp. 303, 14s. net. Two numbers annually; subscription 25s. net, post free.)

⁶ *Diseases of the Nervous System*. By Smith Ely Jelliffe, M.D., Ph.D., and William A. White, M.D. Second edition. Philadelphia and New York: Lea and Febiger. 1917. (Med. 8vo, pp. xix + 938; 424 figures, 11 plates.)

⁴ *The Biological Aspects of Warfare*. By Harry Campbell, M.D., F.R.C.P. Reprinted from the *Lancet*. London: Baillière, Tindall, and Cox. 1918. (Demy 8vo, pp. 44, 1s. net.)

⁵ *Laboratory Studies in Tropical Medicine*. By C. W. Daniels, M.B., F.R.C.P., and H. B. Newham, M.D., M.R.C.P. Fourth edition, thoroughly revised, with new and additional illustrations. London: John Bale, Sons, and Danielsson, Limited. 1918. (Demy 8vo, pp. xv + 560; 164 figures, 6 plates. 21s. net.)

British Medical Journal.

SATURDAY, APRIL 6TH, 1918.

MEDICAL WAR LITERATURE.

Is it too much to say that France is winning again the place she has held and lost more than once as the spiritual and intellectual leader of the nations? Partly from love of peace, partly from an easy tolerance of ways she neither understood nor admired, she had submitted even more completely perhaps than this country to the miasm of German propaganda. German agents insinuated themselves into her trade and commerce, and were setting up a claim to lead her in literature and art. German intellectuals, as they have now admitted, aimed at bringing the thought and art of other nations into subjection, as their rulers aimed at a world hegemony which would enable them to compel all other peoples to accept their Kultur and their political control. The response of the French—some politicians apart—to the intense stimulus of war has excited the unfeigned admiration of those who believed in the spirit of the race and the astonishment of those who thought her decadent. We have drawn inspiration from her high spirit when, in 1914, she was, as it seemed, beaten almost to her knees before the Marne. We have sought to imitate her constancy during four weary winters, and to-day we can understand the courage with which she is facing the fresh turn of ill fortune she is sharing with us. The rebound of the French mind, when the weight of suspense was removed and the worst was known, has shown itself in many ways and not least in the remarkable achievements of some of her imaginative writers, not a few of whom have been discovered within the last three or four years. There have been some remarkable English and Canadian books, but no such efflorescence as in France. In the domain of science Germany has been seeking for a generation to impose herself as the arbiter of reputations and the source to which every one must go who desired to understand the progress of science. Without seeking to belittle the contributions Germany has made to science, it may yet fairly be said that she relied far more on establishing herself as a kind of court of appeal, and one of her chief instruments was the laborious collection and lavish publication of abstracts and the compilation of large and costly works of reference. Left to her own resources, as she has been more or less during the last four years, she has failed to maintain her claim to supremacy in science. Systematic search through German medical publications has yielded very little worthy of reproduction.

In clinical medicine and surgery France has undoubtedly taken a leading place, and on more than one occasion recently we have heard the reproach that Great Britain has been outdistanced by her in the production of medical writings relating to the war. The accusation thus bluntly stated is unpalatable, but it contains a certain element of truth. So far as it concerns the bulk and value of the work done in the scientific investigation of the problems newly raised or raised anew by the war, it is not to be accepted. The researches conducted, mainly under the inspiration of the Medical Research Committee, into the etiology and prevention of the typhoid

fevers, the dysenteries, and cerebro-spinal fever, are not only of present application, but are permanent acquisitions; so, too, is the work done with regard to disorders of the heart, and in orthopaedics. We may also point with well-founded satisfaction to the way in which the many hygienic problems arising in connexion with munition workers have been tackled under the direction of the committee appointed for this purpose. The contributions made by British surgeons to the prevention and treatment of wound infections can also bear comparison with anything done in France; but in the investigation of the nature and treatment of the psychoneuroses of war we have learnt nearly all that is new from France, and the lesson does not seem yet to be thoroughly understood.

The reproach against this country, that it has been backward in the production of medical literature bearing on the war, finds most of its justification in the failure of English publishers to issue books in which men having recent experience of war conditions summarize the best opinion for the use of medical officers in daily contact with the sick and wounded, and the new problems they present. Some excellent books of the kind have been published by British writers, but the total output has not been large. The Oxford Press made a good beginning, but its effort seems to have died away; the Cambridge Press has done little or nothing; and the London University Press has found no better means of meeting the demand for something like a war library than to issue translations of the set of original handbooks published by Masson in Paris (Collection Horizon). This is a well-deserved compliment, but judging by the very high standard of many of the clinical papers on military medicine and surgery published in the English medical periodicals, native writers competent to deal with almost the whole range of subjects could with a little encouragement from the army authorities and the display of a little more energy by publishers easily have been found.

Probably no one not actually concerned with the conduct of medical periodicals appreciates the difficulties under which they are being carried on. The shortage of paper is one of the chief; in the imposition of restrictions on the amount of paper that may be used there has been no attempt at discrimination. So far as we have been able to observe there has been no very noticeable diminution in the bulk of the principal German medical periodicals. A good many of the smaller French medical periodicals stopped publication when the war broke out and many of these have not reappeared, but those which have been continued show no appreciable diminution in size, and as witness to the vitality of French medical thought the reduction in numbers has perhaps been rather an advantage. Our rulers seem to have given no thought to the need for allowing the medical press to present British work in clinical and scientific medicine in a way adequately to show its excellence to observers and practitioners in our own and other countries.

NEURASTHENIC PENSIONERS.

BREAKDOWN of the nervous system, due to the effect on certain temperaments of the strain of active war conditions, may manifest itself in several different ways, and there seems some danger of confusion of ideas as to the proper method of treating such cases in their various forms and stages. No quite satisfactory general term has been found to apply to them. The speech of the Minister of Pensions at Worcester dealt with pensioners who were spoken of

as "neurasthenic," and the term may be used here, although it is not wholly satisfactory.

Professor Elliot Smith, in a valuable letter to the *Times* of March 22nd, stated that as the outcome of a series of informal conferences at the War Office it was unanimously agreed "that neurasthenic patients should not be mixed with other patients, but should be sent to large hospitals specially set apart for the expert treatment of nervous and mental ailments." Sir Alfred Keogh adopted the recommendations of this informal conference of specialists representing all parts of the country, and they are now being put into practice.

Professor Elliot Smith fortifies his own opinion by reference to the view expressed by Colonel Aldren Turner in his preface to the translation of Roussy and Lhermitte's *Psychoneuroses of War*. "There would appear," he said, "to be general agreement upon the value of the segregation of soldiers suffering from the psychoneuroses, and three years' experience has justified this principle. But it is essential that these patients when segregated should be under the care and treatment of medical officers skilled in the special methods of treatment, and that an 'atmosphere of cure' should pervade the special hospital. . . . The chief criticism raised," he added, "against segregation is that the patients imitate each other. . . . Such is not the general experience, and the authors [Roussy and Lhermitte] confirm what has been observed in this country, that evidence of direct 'contagion' of psychoneurotic symptoms from one group of patients to another is quite exceptional." The view expressed by Roussy and Lhermitte in their book is that the psychoneuroses of war, being disturbances based upon a psychical foundation, yield to rational persuasive psychotherapy, which is defined by Brissaud as consisting "of the employment of means destined to demonstrate to the patient his will power and to train what is left of it in the best possible manner." The war having increased the number of these cases and affected their form it is more than ever desirable to apply energetic and rapid treatment, so that the men may be restored to usefulness. In France such patients are treated in neurological or neuropsychiatric centres. The plan has given excellent results, and "rendered great service both to the patients themselves and to the community." Almost all these cases, they assert, are curable.

Segregation, Professor Elliot Smith points out, was deliberately adopted by our own War Office because such a policy as Mr. Hodge is now talking of adopting in the case of pensioners had failed. Widespread experience, Professor Elliot Smith states, has proved "that when patients suffering from the minor mental effects due to war conditions are mixed in general hospitals with other patients, the manifestations of their symptoms, their eccentricities of conduct and behaviour, make them objects of morbid curiosity to their more normal fellow-patients." The consciousness of this, he says, is a serious addition to their troubles and does an incredible amount of harm. In a special hospital, where wise and sympathetic physicians treat neurasthenic patients with skill and insight, there will always be a large proportion of the patients who are in various stages of recovery. Having recently been through the phases of the illness which the newer patients present, they understand their condition and can give them sympathetic help instead of offensive curiosity or misplaced joviality. From the moment of their entry into a special hospital new patients see with their own eyes and learn from their fellows that such troubles as they are suffering from are really curable. And this

"curative atmosphere" becomes one of the most valuable therapeutic agents in restoring these men to a normal condition of mind.

To this Sir Robert Armstrong-Jones, Drs. Caiger and Fox, and Sir George Savage have replied that, while segregation of soldiers suffering from shell shock or neurasthenia may be desirable, it is impracticable for pensioners, most of whom have already been for a long time in hospitals and are now free to choose for themselves. The segregation of pensioners in the later stages of convalescence is condemned. Such men, it is argued, should be treated in village centres, where they would mix with men suffering from all kinds of curable disablement (physical, nervous, and mental) during the convalescent period following discharge from the army. In such centres they would be in healthful and encouraging surroundings, working in congenial occupations, and, if possible, training in the open air. If we could get our terms properly defined it would probably turn out that there was no real conflict of opinion. The point at which the Ministry of Pensions seems to be going wrong is in making the assumption, which appears to underlie its methods, that because a man has been for a long time in hospitals and has been discharged from the army he is incapable of being benefited by the direct method of skilled treatment, which has been so brilliantly worked out in France, and applied with so much success in military neurological centres in this country, as was described by Major Hurst and Dr. Fearusides during a discussion at the Royal Society of Medicine recently reported in our columns (p. 345). We agree with Professor Elliot Smith that the Pensions Minister "might take a leaf out of the War Office's policy and see that the pensioners obtain the efficient and sympathetic treatment which is being provided by the special neurological hospitals of the Army Medical Service."

THE APPEAL TO MEDICAL MEN BY THE MINISTRY OF NATIONAL SERVICE.

LAST week, at the request of the Ministry of National Service, we published an appeal to medical men who had served with temporary commissions in the R.A.M.C., to volunteer to serve again. The response to the appeal has, we understand, not been unsatisfactory, and has been particularly good from Scotland. We have no information as to Ireland. The appeal is renewed this week, and it is hoped that among those who respond may be a considerable number of medical men with operating experience. We were unable last week to give any specific information as to the conditions of service volunteers were asked to accept. Those to whom telegraphic communications were sent have been informed, as have also the Local Medical War Committees, that the Ministry of National Service has undertaken that the case of any doctor now responding to the appeal, who may desire on personal grounds to return home, or whose presence at home becomes greatly needed to meet civil requirements, shall be reviewed by direction of the Ministry at the close of the present crisis, or in any case not later than six months from the date of joining, with a view to his being released, unless the Ministry, after considering the military and civil necessities at the time in consultation with the Statutory Professional Committee, decides that this is impossible from a military point of view. The hesitation in giving a more definite undertaking may be attributed partly to the uncertainties of the future, and partly to the intention of the War Cabinet to raise the age limit for military service. The Prime Minister, in a statement issued last Saturday, said that "in addition to the

action taken to meet the immediate needs of the moment, it will be necessary to bring into operation certain measures which have long been in contemplation. It is clear," he continued, "that, whatever may happen in this battle, the country must be prepared for further sacrifices to ensure final victory," and he added that the necessary plans had been carefully prepared and would be announced when Parliament meets. The reference is assumed to be to the intention to raise the age limit. Parliament meets on April 9th, and it is expected that on the following day the Minister of National Service will introduce a bill to raise the age limit to 50 and to deal drastically with existing exemptions. The bill will probably become law without much delay, and it is to be noted that the attitude of the Ministry of National Service towards medical men is likely to be materially modified so soon as the Government plans are made public. It would only be reasonable that the Ministry should in the future give special consideration to the desires of those medical men who now come forward to resume commissions previously relinquished. It will be remembered that as long ago as June, 1916, the War Office announced its readiness to give commissions in the R.A.M.C. to medical men between 45 and 55 willing to undertake whole-time general service in the United Kingdom. The offer was then made owing to the great demands upon the Army Medical Service. These demands had not notably diminished before the recent reverse on the Western front, and the losses in medical personnel which have been sustained and the large number of wounded who require treatment make the demand still more urgent to-day. As was then pointed out, every senior man who offers himself for whole-time general service in the United Kingdom will set free one younger medical officer now employed in this country to serve abroad.

THE MEDICAL SERVICES DURING THE RETREAT.

It is now certain, as was generally supposed, that a very considerable proportion of the prisoners claimed to have been taken by the enemy in the early part of the present offensive were wounded men who had to be left behind on the field of battle. Military considerations made it a matter of extreme difficulty to collect and evacuate casualties during rapid retirement over a wide area. The losses to the R.A.M.C., both in personnel and in stores, must have been heavy, though there is reason for believing that the staffs of the advanced casualty clearing stations which had to be evacuated were got back in safety. Some of these units were able to close up fairly early, but many did not evacuate until the last moment; indeed, until they were practically in the firing line. So far as possible, the sisters were sent back first, then the patients, and the personnel last of all. The difficulties of arranging for ambulance trains and other transport on a large scale during a period of congested traffic must have thrown a very heavy strain upon the administrative medical officers, for in such confused and changing circumstances the exact moment when evacuation should take place is obviously a decision of extreme responsibility. As might be expected, the difficulties in a number of clearing stations were increased by the presence of patients and personnel from more advanced medical units which had been evacuated by road somewhat earlier in the retirement. Nevertheless, we believe that not only these patients but those in attendance on them were all taken back to safety, and the various units are already in course of re-formation behind the present battle line. A great deal of hospital equipment and medical stores of every kind must inevitably have been lost, but this is easier to replace than trained personnel. All accounts agree as to the splendid behaviour of the sisters and nurses of the evacuated units, many of whom lost everything they possessed, and were for a time in great danger. As for the wounded men who have been streaming down to the bases and across the Channel, we

learn from competent observers that they have kept throughout in remarkably good spirits. Taking them as a whole, the cases seem to have been on the light side. A good many patients evacuated during the first few days were suffering from the effects of gas.

ACUTE POLIOMYELITIS AND STREPTOCOCCI.

THERE are two distinct views as to the significance of certain streptococci cultivated from the nervous tissues of cases of acute poliomyelitis. Rosenow, Mathers, and others regard them as causally related to the disease, and even related to Flexner and Noguchi's globoid bodies, while Bull, Kolmer, and others look on them as secondary invaders and devoid of any etiological significance. The question has important bearings on the prophylaxis and treatment of acute poliomyelitis. The treatment of the disease by the injection of serum from convalescents has been shown to be effective, but much more success in the production of antibodies against the poliomyelitis virus has been claimed for these streptococci, and the serum of a horse (Rosenow's antipoliomyelitic serum) immunized by these streptococci has been stated to possess neutralizing, protective, and therapeutic properties in human poliomyelitis. Amoss and Ebersson¹ of the Rockefeller Institute for Medical Research have experimentally investigated the power of Rosenow's serum to prevent poliomyelitis in monkeys subsequently injected with the virus of poliomyelitis, and have compared it with the known power of the injection of the blood serum of convalescents from the disease to produce this protection. They have not found any evidence that Rosenow's serum is effective therapeutically in monkeys, or that it possesses any antibodies of the same nature as those present in the blood of monkeys or human beings convalescent from the disease.

CULTIVATION OF TUBERCLE BACILLI FROM THE BLOOD.

IN spite of the large amount written on the presence of tubercle bacilli in the blood there is little information based on sound investigation, and the incidence of bacillaemia has been variously estimated. In 1909 Rosenberger excited considerable incredulity by finding bacilli in the blood of 100 per cent. of 49 cases, and later of 300 cases, by staining the centrifugalized sediment from citrated blood; and subsequently Kuraslidge found tubercle bacilli in the blood of apparently healthy people. These improbable results were later explained by the frequent presence of acid-fast bacilli in distilled water and by the production of artefacts resembling acid-fast bacilli in the staining of films when the antiformin method is employed. Fallacies have also arisen in connexion with the more reliable inoculation test of guinea-pigs, namely, confusion between tuberculous and non-tuberculous lesions. After allowing for probable errors, Miss Mildred C. Clough,² of the Johns Hopkins Hospital, estimates, on the basis of the inoculation test, that in generalized tuberculosis tubercle bacilli have been found in the blood in 66 per cent. of cases, and only in 7 per cent. of other forms of tuberculous infection. Suitable cultural methods would probably give positive results more promptly and more regularly than animal inoculations, and to this question of technique Miss Clough has paid much attention. Up to the present the only positive blood culture was that reported by Faber in a case of generalized tuberculosis. By means of blood cultures Miss Clough has now obtained positive results in five out of seven cases of generalized tuberculosis, and found blood cultures negative in nine cases of other forms of tuberculosis, guinea-pig inoculations in four of these cases being also negative. In the pleuritic fluid in one case, and in the cerebro-spinal fluid in seven, smears were

² M. C. Clough, *Amer. Rev. Tuberculosis*, Baltimore, 1917, 1, 593-621.

negative, while cultures were positive. Cultures are therefore valuable in the diagnosis of generalized tuberculosis, in the study of bacillaemia in other forms of tuberculous, and in the examination of spinal, pleuritic, peritoneal, and arthritic fluids when smears do not show tubercle bacilli.

MEDICAL TERMS IN THE NEW ENGLISH DICTIONARY.

THE first word in the new section¹ of the *Oxford English Dictionary* had at one time a definite medical significance, an obsolete meaning of supple being "to soften or mollify a wound or swelling by applying an unguent, a fomentation, etc." A quotation (1579) from a work by Langham illustrates this former meaning: "Apply them to supple, mollifie, ripen, and dissolve all kindes of tumours, hot or cold." A more familiar term is *suppository*, from Lat. *supponere*; it has an illustrative quotation from Lanfranc's *Chirurgie*, of about the year 1400; and in 1583 it was used by Melbancke figuratively (!) in *Philotimus* in the words, "It is not my purginge pilles . . . but Cornelius his swete suppositorye, that must minister you physicke." A large group of medical terms begin with *supra-*, such as *supraclavicular*, *supraorbital*, *suprarenal*, *suprascapular*, and *supraspinatus*. Under *suppuration* there is a full selection of illustrations, the earliest being from Copland's *Galen* of the year 1541. Mr. Onions, who edits the present part of the *Dictionary*, deals most interestingly with the word "surgeon." It is used in three senses. The first is also the widest, for it includes one who practises the art of healing by manual operation (the strictly etymological significance), a practitioner who treats wounds, fractures, deformities, or disorders by surgical means; in early use often more widely, a medical man, a doctor; now specially, one who holds a licence or diploma from the Royal College of Surgeons or any other body legally qualifying him to practise in surgery. The second meaning is that of a medical officer in the army or the navy; and the third is the figurative—for example, "I am the Lorde thy surgione," from Coverdale's *Bible* (Exodus). Another word whose older medical meanings are interesting is "sweat"; at first it signified the life blood, and, later, by a curious series of changes came to be one of the secretions of the skin.

ARTERIO-SCLEROSIS.

ONE of the many pitfalls which beset the path of the vital statistician is illustrated by what has happened with regard to the attribution of a greatly increased number of deaths to arterio-sclerosis since the term was first used in the Registrar-General's tables in 1911. The deaths so returned grew continuously from 3,675 in 1911 to 8,012 in 1916. As Dr. Stevenson, in his review of the statistics of the year, observes, it is impossible to suppose that the disease can have in reality showed any corresponding increase of fatality during so short a period as six years. When the figures are analysed further the coincidence becomes more striking; if the deaths of 1911 be taken at 1,000, then those of the five succeeding years were respectively 1,388, 1,769, 2,010, 2,174, and 2,180. The chief growth, therefore, occurred in the period 1911-1914. The frequency with which the condition occurred as a cause of illness and death had by 1912 aroused so much professional interest that in that year the Local Government Board published the first of a series of reports upon the subject by Professor F. W. Andrewes, F.R.S. Another cause which it is thought may have contributed to the result was the issue by the Registrar-General in the same year of suggestions to medical practitioners in regard to certifications, in the course of which the inadequacy of "old age" as a form of

death certification in those cases in which the disease causing death could be stated was pointed out. The deaths attributed to old age declined considerably in subsequent years. In 1911 they constituted 346 per 1,000 total male deaths at ages over 75; in 1916 they constituted 267. It is thought probable that in many cases the change was brought about by mention of that disease of old age which at the time was attracting so much attention. The surmise is supported by the fact that the growth, from 1911 to 1916, in mortality attributed to arterio-sclerosis was greatest in old age, increasing with each quinquennium from 55 to 60 onwards. Of the deaths attributed to arterio-sclerosis only about 3 per cent. occurred under 50 years of age and 40 per cent. under 70. The restriction to old age applied a good deal more to females than to males, 67.6 per cent. of all the deaths of females occurring after 70 years of age, as against 55.5 of males. This was to be expected in view of the fact that the proportion of women living at these ages was very much greater than that of men. Further analysis of the statistics showed that excess of male mortality was greatest at from 55 to 70 years, and thereafter diminished progressively. It does not appear at present possible to carry the matter much further, for a very large number of deaths are still attributed to cerebral haemorrhage and apoplexy, and a certain number to cerebral atheroma. Dr. Stevenson points out that until 1901 nearly all deaths from lesions of the cerebral arteries were grouped together under the heading "apoplexy"; this heading was first subdivided into "cerebral haemorrhage, cerebral embolism," and "apoplexy, hemiplegia," 55 per cent. of the deaths being attributed to the latter heading; by 1916 the proportion had fallen to 25 per cent. In commenting on this, Dr. Stevenson observes that twenty years ago it was customary in such cases to certify the condition, apoplexy or paralysis, resulting from the cerebral haemorrhage; then the matter was traced one step further back to the vascular lesion; and now another change is in progress by which the cause of the cerebral haemorrhage is recorded and the death is therefore allocated to arterio-sclerosis. He thinks that a further stage of the same process may possibly even now be transferring some of these deaths to Bright's disease in so far as it is regarded as causing arterio-sclerosis, while a still further stage would transfer them to the toxin (lead, gout, etc.) underlying the renal or arterial disease. The growth in the number of deaths attributed to arterio-sclerosis implies a corresponding diminution in numbers listed to other causes, so that an artificial decline in mortality from certain causes dependent on arterial disease must result. The importance of ascertaining as far as possible to what causes these deaths would have been allocated in the absence of mention of arterio-sclerosis, and how the numbers so lost to various other headings compare with the numbers still allocated to them, is recognized, and investigation of the matter is in hand, but has been interrupted by the war. A preliminary examination of the certification of deaths in London males in 1914 tends to show that cerebral haemorrhage loses more deaths than any other one cause from the increasing popularity of arterio-sclerosis as a form of certificate.

SPECTACLES FOR SOLDIERS.

THE army authorities, we are informed, do not supply soldiers with spectacles whose lenses have a strength of less than one dioptré. It has been suggested that this is a mistake, and inflicts an unnecessary hardship upon the men. It seems to us that a distinction should be made between soldiers in the field and those engaged in office duties. The men in the Army Pay Offices and the Record Offices, for instance, often work for very long hours, and many of them suffer from eye-strain in an aggravated form. Ophthalmic surgeons who work near these offices

¹ *A New English Dictionary on Historical Principles*. Vol. ix, Si-Th; Section Supple-Sweep. By C. T. Onions, M.A. Lond. Honorary M.A. Oxon. Oxford: At the Clarendon Press. March, 1918. (Price 5s. net.)

must have been struck with the number of soldiers who consult them for this cause. In times of stress the hours of work are very long, twelve to fourteen hours being not uncommon. It is essential, in these circumstances, that any error of refraction or of muscle balance shall be accurately corrected, and we think that for these men the rule should be modified. In the case of soldiers on active service in the front area conditions are different. Many of them do not use their eyes for much close work, and men with gross errors of refraction are eliminated. It is important to keep the spectacles as simple as possible; they are frequently lost or broken, and the arrangements for replacing them must be easily worked. For these men small errors are not at all important, and even were glasses provided they would not be worn. The object is to give good average acuity, rather than to prevent eye-strain. Young healthy men living an outdoor life do not suffer from asthenopia, and so do not require glasses of low power. But even in this case it seems to us that a cylinder as low as half a dioptre might be allowed when combined with a sphere of one or more dioptres. As far as we can learn the arrangements made for the supply of spectacles to the troops have worked well, and a good substantial article has been provided.

DRIED MILK.

THE Local Government Board has issued an admirable report by Dr. F. J. H. Coutts on Dried Milks, with special reference to their use in Infant Feeding.¹ As a result of exhaustive inquiry Dr. Coutts is satisfied that dried milk is a valuable food, possessing certain special advantages which are likely to lead to its use being greatly extended in the future. In the first place, the labour and cost of transporting the water (which represents about seven-eighths of the total weight of fresh milk) are avoided. Dried milk is also easily handled and stored, while under suitable conditions it remains fit for food for reasonably long periods. It is convenient and economical in use, for the consumer can make up just what is needed for a particular occasion and no more. Dried milk is not germ-free, but the proportion of bacteria contained is extremely small as compared with ordinary milk, and bacteria do not tend to multiply on keeping. While dearer than an equivalent amount of fresh market milk, it is cheaper than milk specially prepared for infants. Dr. Coutts has obtained a great deal of evidence to support the view that when breast feeding is impossible dried milk of recent manufacture, made carefully under hygienic conditions from a good quality of cow's milk, is a very valuable food for infants. There are several processes for preparing milk powder, but two methods are most commonly employed: in the one liquid milk is sprayed over metal cylinders heated internally, in the other after partial condensation it is sprayed into heated air. The chief aim is to get milk in a solid state with as little change as possible in its constituents. When carefully prepared from good fresh milk the powder keeps for several weeks or months, if moisture is excluded, but it is generally conceded that the product of the hot roller process keeps better than the powder made by spraying milk into hot air. On mixing one part by weight of the dried powder with seven parts by weight of warm water a liquid is obtained corresponding in composition to ordinary milk, though with a slight "boiled" taste; there is a tendency for a little solid matter to settle and for fat to rise to the top. Dried milk made from full-cream milk contains 26.62 per cent. of fat, 24.46 per cent. of protein, 36.98 per cent. of milk sugar, 6.12 per cent. of mineral matter, and 4.32 per cent. of water. As put on sale in this country the powder usually comes under one of four classes: full cream, three-quarter

cream, half cream, and skimmed. For infant feeding the full cream variety should alone be used in ordinary cases, in dilutions suitable to different ages. When made up with the proper amount of water it contains the essential food elements in a proportion more suitable for the baby than diluted full-cream sweetened condensed milk which contains an excess of sugar. Thus it comes about that at official infant welfare clinics the use of dried milk is increasing, as on the whole the most suitable food for babies when they cannot get breast milk. Prolonged experience at infant welfare centres indicates no ground for fearing that dried milk leads to scurvy or rickets, but it is thought desirable to give a little orange or grape juice to the baby once or twice a week. There is evidence to show that dried milk is also a valuable food for nursing mothers. While the processes used in drying milk largely reduce the proportion of bacteria present, special precautions must be taken to avoid recontamination during powdering and packing of the dried product. Hence the most scrupulous cleanliness should be observed in the factories; when milk is dried at the farm special premises should be set apart for the purpose, and the milk should be dried as soon as possible after it is drawn from the cow.

THE MATERNITY AND CHILD WELFARE BILL.

THE Maternity and Child Welfare Bill, introduced by the President of the Local Government Board on March 14th, bears evident signs of being a compromise, and leaves some doubt whether it is not a compromise so weak as to be practically useless. As will have been gathered from the note published on March 23rd, p. 354, it proposes that a local authority may make such arrangements as may be sanctioned by the Local Government Board "for attending to the health of expectant mothers and nursing mothers and of children who have not attained the age of 5 years and are not being educated in schools recognized by the Board of Education." The local authorities are to be the county councils and councils of any borough or urban district with a population of over 20,000 or any district council which may be judged to be in a better position to make arrangements than the other councils. The proviso that nothing in the Act "shall authorize the establishment by any local authority of a general domiciliary service by medical practitioners," is apparently designed to prevent the establishment of a second domiciliary service side by side with the panel service under the National Insurance Acts. Provision is made for the constitution and appointment of maternity and child welfare committees by such local authorities as exercise their powers under this Act or under the Notification of Births (Extension) Act, 1915. It will be noticed that the bill is purely permissive; it would be for each local authority to determine whether it should or should not make arrangements for attending to the health of the mothers and children. Judging from past history, it seems probable that if the bill were to become law in its present form the more progressive local authorities would take advantage of it, but that a very large proportion of local authorities would not, especially as they could find many excuses for doing nothing in the conditions produced by the war, which must continue for some time after its termination. On the other hand, there are a good many recent instances of permissive legislation which, after it has been put into force in a number of districts, has been made compulsory throughout the country, and the idea of the Local Government Board may be that the precedent should be followed in this case. However this may be, it is quite clear that the bill does not in any way satisfy the demand for the establishment of a Ministry of Health. It would be one of the first duties of such a Ministry to give attention to maternity and child welfare, and the ineffective nature of Mr. Hayes Fisher's bill is really an additional argument for the speedy establishment of a Health Ministry.

THE WAR.

LESIONS OF PERIPHERAL NERVES RESULTING FROM WAR INJURIES: PATHOLOGY AND TREATMENT.

THE following is the conclusion of the report of the meeting at Alder Hey Military Orthopaedic Hospital on December 8th, 1917, the earlier part of which was published last week, p. 379.

RE-EDUCATION AND FUNCTIONAL DISABILITIES OF ACTIVE SERVICE.

Dr. WILLIAM CUTHBERT MORTON, having outlined the methods adopted by him in investigating functional cases, went on to deal with their treatment. The patient was first assured that while his disability was very real, there was no reason why it should not yield to treatment. If any part of the disability was due to actual and permanent damage to the tissues, he was warned not to look for any improvement in this direction. If an organic lesion was causing no trouble except through suggestion, he was assured that this was not disabling him. Where there was no organic lesion, or one which caused no trouble whatever, he was told that through shock or otherwise he had lost control of his muscles, which required to be disciplined if he was to regain control. As far as possible he was trained to observe what muscles were at fault, and wherein the fault lay, so that when the treatment was being carried out he might realize what he was to try to do, and, above all, when he had succeeded in doing it. If there was inco-ordination he was taught, first, to relax all the muscles of the part, and then to execute the particular movement in the simplest and most natural way. When a muscle was in spasm it should be made to relax by removing all tension, or else by stretching it either by manipulation or by splinting. A flaccid muscle might be induced to contract by gentle tapping, but it was better to employ electricity, or what was called excitation. Electricity was employed in the form of the faradic current with two terminals, or in a bath. In the bath all the muscles of the part were simultaneously stimulated by the same current, so that the strongest group of muscles would prevail. Simultaneous faradism had been applied independently to each of the great nerve trunks of the part; by regulating the strength of current for each nerve it was possible either to balance the muscles against each other or to cause each group in turn to prevail over its antagonists. In this way the muscles worked under varying tension, and their sensory nerves conveyed to the spinal cord and higher centres impulses which tended to recall to the patient the sensations which accompanied the vigorous use of the limb before it was disabled. Excitation consisted of smart simultaneous active and passive movements. If a muscle were suddenly stretched it would contract in order to save itself from injury. It would be suddenly relaxed only by stretching its antagonists, and it would then contract reflexly in order to steady the joint. If these passive movements were made to coincide with active effort on the part of the patient each group of muscles would be trained to contract or relax at the moment when its antagonists were relaxing or contracting. Besides excitation, special exercises were often needed, for an almost trivial change in the re-education might make all the difference in the result; a slight readjustment of the muscular effort, for instance, might double the stride. Massage, gymnastic exercises and drill all had their place. Massage was of value chiefly where muscles had become atrophied through disuse, as in a flaccid limb, or worn out through overaction, as in long-continued clonus. In spastic cases electricity and massage were actually harmful. Hypnotism was never employed.

USE OF MEMBRANE IN NERVE SUTURE.

Major R. C. ELMSLIE pointed out certain difficulties in diagnosis, more especially in cases showing a functional element added to an organic lesion. He also alluded to the difficulty of knowing how to act in cases where the paralysis had followed immediately after an injury; he was inclined to think that such cases should be more frequently subjected to exploratory operations. With

regard to wrapping sutured nerves in membrane, he mentioned an instance in which the nerve was exposed some time after this procedure and found for a distance of three inches to be converted into a dense mass of fibrous tissue of cartilaginous hardness. In this mass of tissue were seen small pieces of Cargile membrane. His preference was for fascia containing fat. He criticized Captain McMurray's opinion that the tendo Achillis should be divided in all cases of lesion of the external popliteal nerve.

TESTING AND RECORDING OF FUNCTION.

Captain BURROW emphasized the importance of co-operation between surgeons and neurologists, and the desirability of having in all centres a uniform method of examining and keeping records of cases, and described the methods employed by him at Leeds for testing and recording sensory and motor functions. Electro-diagnosis was most useful in conjunction with careful neurological examination. When careless short cuts were taken and electro-diagnosis was asked to give a full diagnosis, errors must arise. Electro-diagnosis would tell the observer something of the state of the nerve and muscle that was under the electrode, but nothing as to the actual condition at the site of the nerve injury. A positive response to faradism was always useful; it definitely decided the reflex lesions and functional cases and gave information in partial organic lesions. Absence of faradic response meant very little, especially in muscle groups which had been neglected. He had seen faradic response return a few days after careful splinting of an overstretched group of muscles. Voluntary movement was also present in many muscles as a lesion recovered before faradic response was obtainable. A living muscle with varying chemical changes was liable to change polarity. In well nourished muscles with the limb warm he had often noted the KCC greater than the ACC even in complete division of the nerve of supply. The character of the contraction was much more important. The slow vermicular contraction or longitudinal contraction which passed like a wave from the neighbourhood of the testing electrode was usually found to be associated with complete lesions of nerve conductivity.

The diagnosis was often completed at operation, when the exposed nerve was tested for conductivity by the faradic current. He condemned the rough naked eye decisions made by some surgeons as to the conductivity of a nerve, for clinical and microscopical evidence proved them to be wrong again and again. There might sometimes be more loss of function after operation than before it, but the loss incurred temporarily was often unimportant when perfect adaptation of the cut ends was obtained. The eventual recovery of function was often much more rapid after total division and suture than after operations for the freeing of the nerve.

OPERATIVE TREATMENT OF EXTRAMURAL AND INTRAMURAL DAMAGE.

Major S. ALWYN SMITH said that he used a sleeve from the tensor fasciae femoris as a covering in all cases where scar tissue which could not be fully removed surrounded a nerve, and also in all cases in which linear capsulotomy was performed for interstitial fibrosis. No undue formation of fibrous tissue resulted. Dissection of a case operated upon five months previously showed that the sleeve had not changed its character, and that it was easily separated from the subjacent capsule of the nerve.

He asked for opinions as to the operative procedure to be adopted in the following circumstances:

1. *Extramural Damage.*—Cases of long-continued damage due to aneurysms which had produced traction and pressure on a nerve, or to scar tissue producing constriction, where the nerve capsule was intact, but where the damaged portion of nerve was found like string or tape and did not conduct mild faradic current. He had encountered three such instances. Was it advisable to sacrifice the damaged portion, followed by end-to-end suture; or, as had been his custom, was it sufficient to perform linear capsulotomy with or without a fascial sleeve? So far he had not obtained good results in the few cases of this description that he had encountered.

2. *Intramural Damage.*—Partial lesions showing well-marked interstitial fibrosis, more or less diffuse, might

slightly conduct faradism applied directly at operation, and were often the origin of causalgia. Was it justifiable to remove the damaged portion and perform end-to-end suture, or had the results of removal of the fibrous nodules and capsulotomy been satisfactory? He had had several cases of this nature in which he had been inclined to take the heroic course, despite the fact that one or two muscles whose nerve supply was derived distal to the damage were still acting.

ELECTRICAL EXAMINATION.

Captain STANLEY BARNES said that it was important to study the distribution of the muscular atrophy. In nerve section the muscles supplied, if examined a month or more after the damage, were much smaller than those innervated by untouched nerves, although the unaffected muscles might lie adjacent to the atrophied ones and might subserve somewhat similar functions. This was never the case in atrophy due to joint lesions, when all the muscles that could cause movement at that joint showed a fairly level degree of atrophy. A muscle a few weeks after severance from its motor nerves was atrophied and of pale yellow colour. The microscope showed loss of striation, a relative and possibly actual increase in the number of nuclei, and considerable loss of sarcolemma with no loss of supporting structures. This uninervated muscle, owing to its severance from the nervous system, would cease to contract to any volitional stimulus, and if no treatment were applied, would tend slowly to lose its capacity once more to become normal muscle. If any neighbouring healthy muscles when in action moved the lymph flow in this latent muscle, then the process of atrophy was slow, and it might be that suture of its nerves years after section would result in recovery. But in most situations after the lapse of a few years in which no treatment had been maintained, a nerve suture, though surgically successful, would fail to restore function in the atrophied muscle. The reaction of degenerated muscle to electricity was peculiar; to faradism it ceased altogether in a very few days after the axis cylinders had been divided. The galvanic excitability during the early days of the process of degeneration was often increased, but within a fortnight (when faradic excitability was usually lost) the curve of excitability dropped to normal, and from this stage onwards fell gradually, until the final stage of atrophy was reached in which no reaction to galvanism occurred. There was no motor point to a degenerated muscle, for it had no nerve supply. The galvanic electrode was best applied on the bare dissected muscle itself, and this was, in theory, the only way to find out whether the tertiary degeneration—atrophy—was so complete that nerve suture was bound to fail. In practice this was not done, as it involved a further wounding, and it was known from experience that, certainly up to two years after injury, it was worth while to attempt suture.

Any successful stimulus to a degenerated muscle fibre always resulted in an unusual type of contraction; instead of the normal sharp flick, so quick as to appear instantaneous to the eye, which occurred either at the make or break of a continuous current in a normal muscle fibre, there was a slow wavy contraction which took an appreciable part of a second to reach its maximum and an equal time to die down. The same type of contraction could be obtained by mechanical irritation of a superficial muscle like the deltoid when it was lightly but sharply tapped by a percussion hammer. In testing for electrical excitability by faradism or galvanism it was easier to observe accurately which muscle or tendon moved if the muscles were rendered flaccid by light fixation of the limb.

A muscle which had undergone Wallerian degeneration gave no reaction to faradism, showed an altered degree of excitability to galvanism, and gave a slow wave of contraction to galvanism, with a polar reaction of ACC greater than KCC. The combination of these four factors constituted the full reaction of degeneration, but three only were of value. Reaction to faradism meant that some nerve fibres at least were uncut. A negative result was unsatisfactory and galvanic testing was very desirable; a positive slow wavy contraction to galvanism was more reliable than failure of the faradic reaction. The polar reaction was not quite so important. If KCC = ACC it was probable that some healthy muscle fibres were contracting with some degenerated ones; in any case great care had

to be exercised to determine clearly that the reaction referred to the muscle under test only. When the reaction of degeneration was present with a positive wavy contraction to galvanism, physiological nerve section might safely be assumed. A functional or hysterical paralysis gave normal muscle reactions; muscles damaged by local disease or injury or by ischaemic contracture usually gave a feeble reaction to faradism; to galvanism the reaction was quick with KCC > ACC. Whenever a muscle had given this reaction after possible damage to its nerve, all other factors having been eliminated, it had been assumed that the corresponding nerve fibres had been cut.

In examination for alterations in sensation he used pin-prick tests almost entirely. The tendency had been to rely more upon muscle testing than upon sensory changes in advising treatment; only very rarely had any discrepancy in diagnosis arisen. Usually where damage to a mixed nerve was severe but incomplete, the motor damage predominated.

In all cases of complete physiological block of the nerve he had advised operation if reasonably practical. When, however, the lesion was incomplete, as for instance when some sensory fibres were intact, he had waited for a time. On the whole, he had come to the conclusion that he would have done better to advise operation more freely. When some of the muscle supplied gave reaction to faradism, he now advised exploration, unless signs of further restoration of function occurred within a month, as recovery was more rapid after clearing away scar tissue.

Prognosis.

Cases of motor or mixed, and sensory nerves which had been completely divided and subsequently sutured were alone discussed, and it was assumed that the surgical reunion was successful and that the after-treatment was sufficient. Many cases had been recorded in which, after complete section and reunion of the nerve, voluntary power in its muscle supply had returned within a few days or weeks; many more had been recorded in which sensory restoration was claimed within a few days. His own experience, extending to about forty cases of complete section by gunshot wounds and reunion by surgical means, was that no such return of physiological function could be expected for at least six months after suture; that usually nine months elapsed before the first signs of motor recovery occurred; and that full recovery of motor power was to be expected only after some eighteen months or two years. He had seen no evidence of any return of sensory function at an earlier stage than five and a half months, and no case of complete return of sensory function, although he had examined a few cases as late as twenty months after operation.

The point was important because, after suture of a musculo-spiral nerve, the surgeon might assume that the union had failed because no return of function had occurred three months later, and operate again. The records of cases of immediate and rapid recovery (say within six months after suture) were due to errors of observation attributable to mistakes in recognition of tissues at the time of operation, and to reliance on the report of unskilled observers at the time when "recovery" was reported. It was not difficult, when operating in a mass of scar tissue in an axilla, to mistake the internal cutaneous nerve for the median; careful examination was required to determine whether there was any real recovery of motor power in the median motor supply, and the testing of cutaneous sensibility needed considerable skill and consummate patience. Another source of error was incomplete diagnosis before operation—the mistaking of a functional for an organic paralysis.

Discrepancies of observed results as regards return of sensation, and possibly of muscle power, might be explained on the ground that all uninervated living tissue appeared to exert an attraction for neighbouring nerve fibrils. Even without sensory nerve suture, an anaesthetic area due to nerve injury tended constantly to diminish in size, particularly as regards protopathic sensation. Therefore it was not to be assumed that shrinkage in anaesthetic areas after nerve suture was due solely to return of function of the nerve; the impulses might be passing by another route.

If the men disabled by nerve section required a minimum of twelve months' after-treatment, special arrangements

must be made both as regards their army service and their treatment.

Captain PLATT said that in an experience of 106 operations, the great majority of which had been for end-to-end suture or simple neurolysis, he had been specially interested in two types of lesion: (a) those in which there was a localized intraneural scar of great density occupying a definite area in the cross section of the nerve trunk associated with paralysis of one muscle group, and (b) those in which with complete division of a nerve and extensive loss of substance, end-to-end approximation could not be obtained in spite of acute flexion of joints. Working with a fine probe electrode and the Bristow coil, he had been able to confirm at operations the topography established for the median and ulnar nerves in the upper arm. In this type of lesion a simple neurolysis would not influence regeneration in the blocked segment. Careful exsection of the intraneural scar was a legitimate operation, and in his own experience had been followed by good results.

In fourteen cases in which the gap was large he had used nerve grafts. At the present conduction had been definitely established across the gap in three cases only. In a case of median injury in the upper arm, five months after the insertion of a graft two inches in length power had returned in the flexor longus pollicis and there was a diminution in the area of anaesthesia.

Insulation of a nerve after operation rested on a sound physiological basis. He always used fascia; where a graft was used a fascial tunnel was essential. The use of sterile vaseline or olive oil as a preventive of perineural adhesions seemed logical, but he had not been impressed by cases in which these substances were employed.

Radium Emanation.

Captain WALTER STEVENSON spoke of the beneficial effects which he had found to result from the exposure of scar tissue to radium emanations in freeing structures matted together by scar tissue, and in relieving the pain and trophic changes following nerve involvement. The anaesthetic effect of radium on scar tissue was definite and immediate, and persisted for a week or more. This was useful in mobilizing the fixed and painful joints, especially of the hands.

RESULTS OF NERVE SUTURE.

Captain S. W. DAW, after mentioning the indications for and against operation in nerve injuries, gave some details of the method he employed for the union of divided nerves. He preferred a continuous suture of fine catgut; when it was impossible to remove all surrounding scar tissue he wrapped round the suture line with Cargile membrane dipped in hot vaseline. Operations for freeing nerves were often disappointing. He gave details of 35 cases, (great sciatic 5, external popliteal 2, musculo-spiral 5, median 4, ulnar 19). The disproportionate number of ulnar cases, due to the records being more easily got, might have minimized the favourable aspect of the results. The average time between wound and suture was under seven months, and the average time between suture and last examination was also under seven months.

The two external popliteal sutures showed signs of regeneration in improved sensation and electrical response within 2 and 3 months respectively.

Of the five great sciatic cases two showed voluntary movements of flexion and extension of the ankle 17 and 18 months after suture. Two showed improvement in sensation and electrical reaction 4 and 5 months after suture. One showed no improvement 7 months after suture.

Of the five musculo-spiral cases four showed complete recovery 7, 8, 10, and 11 months after suture, three of these having gone back to duty.

The four median cases were all high—that is, at or above the elbow. Two cases showed voluntary action of all muscles 4 months and 13 months after suture. In neither case had sense of light touch returned. The other two showed electrical improvement in 3 and 6 months.

Of the nineteen ulnar cases, four showed good voluntary action, including practically all the hand muscles, 4, 4, 7, and 13 months after operation. Three of these were at or above the elbow, one low in the forearm. Seven showed signs of recovery, such as loss of R.D., return of protopathic sensation, or voluntary movements of individual muscles, 3, 3, 4, 6, 7, 7, and 9 months after suture. These were chiefly low sutures. They included three cases of the interesting but quite unsound procedure of ulnar median anastomosis. In these there was protopathic return over much of the ulnar distribution in the hand, in

one case referred to the tip of the index finger. Time will show how far recovery proceeds, but some permanent loss of function of the borrowed median nerve is feared. The remaining eight ulnar cases showed no signs of recovery. Their average time since operation was under 7 months.

Review of the Results.

	Cases.	
Good recovery of voluntary action	12	roughly 34%
Signs of recovery	14	40%
No results as yet	9	26%

CASUALTIES IN THE MEDICAL SERVICES.

ARMY.

Killed in Action.

LIEUT.-COLONEL J. ROBERTSON, R.A.M.C.(T.F.).

Lieut.-Colonel James Robertson, R.A.M.C.(T.F.), was killed in action on March 21st, aged 39. He was the son of the late Mr. John Robertson of Aberdeen, and was educated at Aberdeen University, where he graduated M.B. and Ch.B., in 1904, M.D. in 1908, and Ch.M., with honours, in 1909; also studying in Dublin, Hamburg, and Berlin. After acting as house-surgeon at the Aberdeen Royal Infirmary and as clinical assistant at the Samaritan Free Hospital and at St. Mark's Hospital, London, he made a voyage to South America, and in 1906 took an appointment as medical officer to a tea garden in the Duars, Northern Bengal. Returning home after about a year, he went into practice in Aberdeen, where he was parochial medical officer and senior assistant anaesthetist to the Royal Infirmary. In his student days he was an enthusiastic volunteer, and on his return home joined the 1st Highland (Aberdeen) Field Ambulance, in which he attained the rank of captain on October 14th, 1911, and of major on November 29th, 1914. During the war he had risen to the command with the rank of lieutenant-colonel, and had been mentioned in dispatches.

CAPTAIN B. G. BEVERIDGE, M.C., R.A.M.C.(T.F.).

Captain Bernard Gordon Beveridge, M.C., R.A.M.C.(T.F.), was killed in action on March 21st. He was the only son of Dr. Beveridge, and was educated at Gordon's College, Aberdeen, and at the university in that city, where he graduated M.B. and Ch.B. in 1912. He joined the 1st Highland (Aberdeen) Field Ambulance as lieutenant on November 21st, 1914, and was promoted to captain after a year's service. He had been in France almost ever since he joined. He received the Military Cross on November 19th, 1917.

CAPTAIN H. DUNKERLEY, R.A.M.C.

Captain Harold Dunkerley, R.A.M.C., was killed in action on March 23rd, aged 28. He was the younger son of Mr. Herbert Dunkerley of Bombay, and was educated at Downing College, Cambridge, where he graduated B.A. in 1912, and subsequently M.A., and at the London Hospital, taking the diplomas of M.R.C.S. and L.R.C.P. Lond. in 1914. After acting as surgical clinical assistant at the London Hospital, he took a temporary commission as lieutenant in the R.A.M.C. on December 1st, 1914, and was promoted to captain after a year's service. He went to the front in 1915, and served for nine months with the Rifle Brigade, till he was wounded and invalided home. Three months later he returned to France, and served successively with a stationary hospital, with the North Somerset Yeomanry, and with a field ambulance.

CAPTAIN E. NEWTON, R.A.M.C.

Captain Eric Newton, R.A.M.C., reported missing in East Africa on August 5th, 1917, is now presumed killed on that date, aged 28. He was the son of Captain I. Newton, medical officer of Bhatinda, and was educated at Aberdeen University, where he graduated M.B. and Ch.B. in 1915, taking a temporary commission in the R.A.M.C. soon after. He was a Scottish international hockey player.

Died of Wounds.

CAPTAIN H. T. LUKYN-WILLIAMS, R.A.M.C.

Captain Herbert Temple Lukyn-Williams, R.A.M.C., died of wounds on March 27th, aged 32. He was the second son of Canon Lukyn-Williams, of Guilden Morden.

and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1911. He took a temporary commission as lieutenant in the R.A.M.C. on February 1st, 1915, and was promoted to captain on completion of a year's service. He was attached to the Sherwood Foresters when he was fatally wounded.

CAPTAIN J. C. METCALFE, M.O., R.A.M.C.(T.F.).

Captain John Clifford Metcalfe, M.O., R.A.M.C.(T.F.), was reported to have died of wounds, in the casualty list published on March 27th. He was educated at Leeds University, and after graduating M.B. and Ch.B. with first class honours in 1912, went into practice at Liversedge, Yorkshire. He joined the 1st West Riding (Leeds) Field Ambulance as lieutenant on October 13th, 1914, and received the Military Cross on June 3rd, 1917.

Wounded.

Major M. A. Power, M.C., R.A.M.C. (temporary).

Captain H. T. Chatfield, R.A.M.C. (temporary).

Captain A. S. Hendrie, R.A.M.C. (temporary).

Captain F. P. Fisher, R.A.M.C. (temporary).

DEATHS OF SONS OF MEDICAL MEN.

Cameron, John Hunter, Second Lieutenant, eldest son of the late Dr. John Cameron, of Lochgilphead, Argyllshire, died at Fatehgarh, on March 4th, of pneumonia following malarial fever, contracted during two years' active service in East Africa, aged 29. He was educated at Cheltenham College and at Edinburgh University, where he graduated B.Sc., subsequently going to India as a civil engineer. A brother, in the Royal Flying Corps, was killed in August, 1917.

Davenport, Arthur Allan Orme, M.O., Lieutenant East Lancashire Regiment, elder son of Dr. Arthur F. Davenport, of St. Kilda, Melbourne, died of wounds on March 24th, aged 24. He was educated at Geelong School, where he was head of the school, stroke of the eight, and captain of football. He got his commission in 1915, served in Gallipoli, being present at the evacuation, and then in Egypt, till January, 1917, when he was sent to another front. He was wounded on April 24th, 1917, and on the same occasion received the Military Cross. He returned to the front on January 26th, 1918.

Drummond, Kearsley, Captain Northumberland Fusiliers, fifth son of Dr. David Drummond of Newcastle-on-Tyne, died of wounds March 24th. He got his first commission on September 12th, 1914.

Macklin, J. J. M., Lieutenant King's Own (R.L.) Regiment, attached to the 12th Lancashire Fusiliers, youngest son of Dr. T. T. Macklin, J.P., of Lancaster, killed in action at Salonica on March 12th, aged 23. He was educated at Plymouth College and the Blackburn Royal Grammar School and subsequently at the Ontario Agricultural College, Guelph, Canada, where he took the diploma in agriculture. He was a member of the O.T.C. there, and was one of six students brought over by the War Office and granted commissions in British regiments in 1915. His health was so much impaired by an acute attack of appendicitis and operation in 1916 that he was gazetted out, but immediately rejoined for home service and six months later was passed fit for overseas and was sent to Salonica. Two of his brothers are serving at the front, one in the R.A.M.C. and one in the Royal Artillery.

Matthews, David J. W., Private Canadian Forces, son of the late Dr. Matthews, of Belmont, Canada, killed February 17th.

Schäfer, John Sharpey, acting Commander R.N., elder and only surviving son of Professor Sir Edward Schäfer, F.R.S., of Edinburgh University, killed at sea March 22nd, aged 36. He joined the navy in 1895, and was for some time naval assistant in the Hydrographic Department at the Admiralty, but had retired previous to the war. His brother, Lieutenant T. S. Schäfer, Northumberland Fusiliers, was killed on September 26th, 1915.

MEDICAL STUDENTS.

Brereton-Barry, W. R., Second Lieutenant, reported wounded and missing on August 16th, 1917, now officially presumed killed, was the second son of Judge Brereton-Barry. He obtained his commission in the Royal Dublin Fusiliers in February, 1916, at the age of 18; served through the rebellion in Dublin, and went to the front in March, 1917. He was a second-year medical student at Trinity College, Dublin. On August 16th he was severely wounded in the arm, but refused to go to the dressing station, and insisted on going forward with his men. He led an advance into the enemy lines, in the course of which his right leg was shattered by a shell. Next morning he sent a note by a runner to his battalion saying he was in a shell-hole within the German lines. Search parties were sent out that night, but failed to find him.

Simon, Frank, killed in France early in January last, was a fourth-year medical student in the School of Physic, Trinity College, Dublin. Immediately upon the outbreak of war he volunteered for active service and received a commission in the Royal Dublin Fusiliers in September, 1914. Since then, until the time of his death, he had been on active service with the B.E.F. in France.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

Two Supplements to the *London Gazette*, issued on March 26th, contain further lists of awards for gallantry and distinguished service in the field. The following medical officers are among the recipients of the awards indicated:

To be *Brevet Lieut.-Colonel*.—Majora (temporary Lieut.-Colonels) R. M. Barrow and M. Mackelvie, I.M.S.

Distinguished Service Order.—Captain J. Scott, I.M.S.

Military Cross.—Captains A. O. Ainsley, R.A.M.C., W. E. H. Bull, R.A.M.C., C. A. Godson, I.M.S., W. Ooldie, R.A.M.C., J. D. Kidd, R.A.M.C., P. J. Moir, R.A.M.C., C. N. Davies, I.M.S., B. M. Take, R.A.M.C.(S.R.), R. G. Walker, R.A.M.C.; temporary Captains W. K. Bigger, R.A.M.C., N. M. Cummins, R.A.M.C., B. Knowles, R.A.M.C., R. Stansfield, R.A.M.C.; Lieutenant C. W. W. Baxter, I.M.S.; temporary Lieutenant V. K. Apte, I.M.S.

The name of Major (temporary Lieut.-Colonel) Charles Algernon Stidston was incorrectly printed in the notification of the conferment of the D.S.O. published in the Supplement to the *London Gazette* of February 4th, 1918 (BRITISH MEDICAL JOURNAL, February 9th, p. 187).

NOTES.

THE MEDICAL SERVICES OF THE BRITISH ARMIES IN FRANCE.

THE KING, who during his two days' visit to the armies in France travelled some three hundred miles and visited many centres, seems to have spent much of his time with the 3rd Army, which holds the line in the neighbourhood of Arras. In the letter he wrote to Field-Marshal Haig on his return to London he spoke of the indomitable courage and unflinching tenacity with which the troops have withstood the supreme efforts of the greater part of the enemy's fighting power. He visited many hospitals and casualty clearing stations, and conveyed his impression of them in the following sentence:

"In a large casualty clearing station I realized what can be accomplished by good organization in promptly dealing with every variety of casualty of greater or less severity, and passing on by trains to the base hospitals those fit to travel. The patient cheerfulness of the wounded was only equalled by the care and gentleness of those ministering to their wants."

MALARIA.

The following Army Council Instruction, which is of general application—that is to say, it includes men belonging to Overseas Contingents—was issued on March 29th:

Officers and men who have been returned home on account of malaria will not in future be available for posting to a theatre of war where malaria is prevalent, namely, Salonica, Egypt, Mesopotamia, or East Africa. They will, however, be available for other theatres of war when otherwise fit. The documents of all such men will be clearly endorsed—"Malaria case—not available for a theatre of war where malaria is prevalent."

Scotland.

CONDITIONS OF ADMISSION TO SCOTTISH UNIVERSITIES.

THE draft ordinance making new regulations for admission to the Scottish universities, which, as has been noted, received the approval of the General Council of the University of Edinburgh last month, is also approved, we understand, by the other Scottish universities. The institution in 1892 of the preliminary examination in each faculty was due to the recommendation of the University Commissioners under the Act of 1889. They made the recommendation with reluctance and looked upon it as a temporary measure only, designed to meet a difficulty which they hoped would be removed as the standard of secondary education in Scotland improved. Before 1892 many students unfit for university study entered the universities, which consequently had to do much work on the secondary school level and to maintain junior classes in such subjects as Latin, Greek, and mathematics, solely to help students insufficiently prepared for attendance at the senior or graduating classes. Only between 10 and 20 per cent. of the students now present themselves for the preliminary examinations; the remainder are admitted through the machinery of the leaving certificate examinations. The universities appear to have agreed that

the time has come to abolish these temporary expedients. The new ordinance, according to the *Scottish Educational News*, "marks a real revolution in Scots education. It is the beginning of the end of externalism in examinations. The question whether or not a student is to be admitted to a graduation course will depend henceforth, not on the result of an examination in one or two subjects, but upon the length and the character of his secondary school course, and on a report from his teachers as to how he did his work during that course. We understand that something in the nature of a concordat has been drawn up between the Universities and the Education Department, by which the leaving certificates will be awarded on the same principle." The Entrance Board will have large powers; it will be able to accept the leaving certificate of the Scottish Education Department or other certificate deemed equivalent thereto. The equivalence will be determined not by examination, but by the result of the work done during the period of secondary education. The intention appears to be to replace the test of a single examination by the more prolonged test of general progress over a number of years. The draft ordinance contains paragraphs co-ordinating this change with the existing certificates from schools in places outside Scotland, but the general principle will be maintained. The change will throw a greater responsibility on the secondary school teachers of Scotland, but is not altogether without precedent; it was tried in the training colleges some fifteen or twenty years ago, and was successful. It is expected that it will be no less successful in the wide field of secondary education.

Ireland.

PARLIAMENTARY REPRESENTATION OF QUEEN'S UNIVERSITY, BELFAST.

A LETTER to those graduates of the university who will have the right to vote has been issued by the honorary secretaries of Sir William Whitla's committee; these secretaries are representative of the faculties of medicine, arts, science, law, and engineering, and also of women graduates. It sets forth Sir William's claims and qualifications, and urgently calls upon all potential voters to write to the secretary of the university without delay and see that their names are properly enrolled, and that everything is in order, so that any mistake or error may be rectified before it is too late. This is emphasized as of vital importance. This is a unique opportunity of obtaining a medical representative who knows the problems of the day, and can devote his whole time to the work. No other medical candidate has appeared, and it is improbable that any will now come forward. Mr. R. T. Martin, B.A., solicitor, senator of the university, who has been much interested in university matters, and Mr. R. M. Henry, M.A., Professor of Latin, are also mentioned as possible candidates.

UNIVERSITY COLLEGE, CORK, AND A MUNSTER UNIVERSITY.

The governing body of University College, Cork, has unanimously expressed its opinion that the success of the College as an institution of higher education in Cork is seriously hampered by its position as a member of a federal university. Besides the inconvenience and waste of time due to journeying between Cork and Dublin, it is held that the dissimilarity of local conditions limits development of the College in various important directions. The Government is therefore called upon to introduce the necessary legislation for constituting an independent university in place of the present dependent college. In making this request the great industrial developments now taking place in Cork are emphasized. The governing body has also issued in pamphlet form a statement in support of the claim for establishing a separate university for Munster.

IRISH ASYLUM WORKERS.

At a meeting of the Down District Asylum Branch of the Asylum Workers' Association, on March 25th, Dr. M. J. Nolan, who presided, pointed out the desirability at the present period of unrest of discussing how best to maintain the honourable position of the association, and to safeguard it from any conduct tending to besmirch its

good name or lower the status of its members in the eyes of the public. On the motion of two of the attendants, a resolution was unanimously carried extending sympathy to those in other institutions who were seeking to better their positions, expressing the hope that such improvement would be secured by the methods adopted by the Asylum Workers' Association, and deprecating very strongly the resort to strikes. At the same time, the view was expressed that committees were not free from blame in failing to provide their employees with suitable remuneration, having regard to the high cost of living.

MORTALITY IN IRELAND, 1866-1915.

Sir W. Thompson, Registrar-General for Ireland, in his address to the Section of State Medicine of the Royal Academy of Medicine in Ireland, dealt with mortality in Ireland for fifty years (1866-1915). Comparing the five-year periods 1866-70 and 1911-15, he showed that while the mortality in England and Wales had decreased 36.4 per cent. and in Scotland 28.7 per cent., in Ireland it had increased by 2.1 per cent. This difference he attributed in a great measure to emigration, the young and healthy going away. Fully 85 per cent. of emigrants in recent years were between 15 and 35 years of age. The infant mortality rate in Ireland in the period 1911-15 was 21 per cent. under that for England and Wales, and 24 per cent. under that for Scotland. At the same time, the figures showed, when compared with the period 1866-70, that, though the infant mortality rate for Ireland had decreased only 4 per cent. and Scotland 7 per cent., that for England and Wales had decreased 30 per cent. As compared with 1866-70, the mortality from tuberculosis in Ireland in 1911-15 showed a decrease of 13 per cent., while the decrease in England and Wales and Scotland amounted to 56 per cent. in each case. The mortality from cancer showed a strong tendency to increase, but the average rate for Ireland was lower than that of any of the three countries. In 1911-15 it was 86 per 100,000 of the population, as compared with 105 for England and Wales and 110 for Scotland.

Sydney.

ROLL OF HONOUR AT THE SYDNEY HOSPITAL.

A ROLL of Honour comprising the names of 131 members of the staffs of the Sydney Hospital was unveiled on November 28th last by Mr. D. Storey, the Acting Minister of Public Health. The Roll, which is hung in the main vestibule of the hospital, is of beaten copper, surmounted by the coat-of-arms of the hospital. The Roll includes the names of Dr. W. Chisholm and Dr. T. Fiaschi of the honorary medical staff; Dr. J. B. Nash, a member of the board of directors, and forty six of the medical staff, four of whom have died on active service—Dr. B. Pockley, the first to be killed at Rabaul; Dr. J. K. Donaldson, Dr. A. C. Jekyll, and Dr. W. R. Aspinall. Of the nursing staff forty-seven, including the matron, have gone on active service. Mr. Storey, who was introduced to the gathering by Dr. A. J. Brady, said it was a great privilege to have the honour of performing the ceremony to commemorate for all time the memories of those who had gone to other regions, and also to have a reminder of those still giving their services to assist in restoring the wounded to health. He did so with the most affectionate and profound reverence to the memory of those who had gone, and admiration for those still at work in the various arenas of war, and with the hope that those still on active service would soon be back again in Australia safe and sound.

MENTAL DEFICIENCY.

A pamphlet has recently been issued from the Government printing office, entitled *Mental Deficiency: a Medico-Sociological Study of Feeble-Mindedness*, by Sir Charles Mackellar, M.B., and Professor D. A. Welsh, Professor of Pathology in the University of Sydney. Sir Charles Mackellar estimates from the statistics of actual insanity that, in the Commonwealth, there are about 20,000 mental defectives, and in New South Wales probably not fewer than 5,000, that is including not only adults but also the children attending the public schools, and many who have

not yet reached the school age. It is contended that crime, prostitution, illegitimacy, drunkenness, and pauperism are constantly recruited from the ranks of the uncontrolled feeble-minded, whose defective brain power renders them unable to inhibit the impulses leading them to violence and indulgence that have very baneful results for the community in which they live. The authors call for legislation to enable the State to take control of the feeble-minded, so as to give them the opportunity of living as useful a life as possible, and at the same time to prevent them from passing on their defective mentality, with all its possibilities of evil, to a new generation. They advocate the life-long detention of mental defectives in farm colonies. While it is recognized that this is a matter of the utmost importance it is not probable than any legislation on these lines will be passed for some considerable time to come.

THE EARLY TREATMENT OF CANCER.

The Department of Public Health is taking an important step in the direction of bringing the subject of cancer, especially its early symptoms and signs, before the general public of New South Wales. The contents of a poster, which is to be attached to public buildings, emphasizes the fact that the only cure for cancer at present known is its early and complete removal. The co-operation of the profession and the public is necessary to secure early recognition. Stress is laid on the fact that cancer in its early and curable stage usually gives rise to no pain or symptom of ill health, though it shows itself in its commonest situations by certain obvious signs. A list of striking symptoms and signs well known to the profession as indications of early cancerous disease is given, and persons who have any of them are urgently advised to consult a doctor without delay. The concluding paragraph states that, though there is no evidence that cancer is communicable from one individual to another, it is desirable that rooms occupied by a person suffering from cancer should be disinfected from time to time and kept scrupulously clean.

Correspondence.

CHARACTERS OF HUNTINGTON'S CHOREA.

SIR,—If you can spare me a few lines more on this malady may I briefly describe another case, superficially resembling that of Huntington's chorea but in nature wholly different from it? A day or two after my dispatch to you of the revised proof of my note on Huntington's chorea I made my official visit to our Heart Hospital at Colchester. Among the soldiers paraded, a man entered the consulting room who for a few moments might have been regarded as a case of Huntington's disease; but for a few moments only. The man had been buried under shell explosion, and suffered a severe shaking. It is true that he tottered and shuffled into the room quivering in all his limbs, and that his movements were tremulous and vacillating. Notwithstanding, when the man came to a stand, it was apparent that the quaverings were rhythmic and symmetrical; the knees, for instance, oscillated thus together to and fro—between three and four times a second; no "Puck-like-twitches." When told to sit down at ease he became more tranquil, and in a minute or two the trepidations diminished almost to quiescence. He could now extend his arm with no more than the atonic tremors of any debilitated man. When asked to write his name, he went to the table, took up a pen, still with no more than simple tremor, and wrote his name in a good steady hand without sign of twitch or jerk in the script. Such distinctions as these seem to me to deserve some emphasis.—I am, etc.,

Cambridge, March 30th.

CLIFFORD ALLBUTT.

"PANCREATIC INSUFFICIENCY."

SIR,—The article in your issue of March 30th, p. 376, raises an important point—namely, the diagnosis of pancreatic insufficiency. I agree that the condition can only be detected with certainty by laboratory methods. There is another question, however—namely, why patients suffering from that condition are to be allowed an extra

ration of meat and fat? The pathology of the disease, and my clinical experience of it during the past ten or twelve years, both suggest that this is unnecessary and, indeed, harmful. Such patients usually do best when their protein is supplied chiefly in the form of casein and gelatin, and their fats are taken in the form of milk, yolk of egg, cod-liver oil, and emulsified fats, as I have pointed out elsewhere.¹ More than a very limited amount of lean meat, with a little butter, is not required. With a diet on these lines and the help of some reliable preparation of pancreas digestion and absorption are generally well carried out, so that the patient's physical condition improves, and, moreover, there is no economical loss to the community such as a diet like that the Food Controller's advisers seem to think advisable would entail. In some instances cream is well borne, and may, in fact, be regarded as an essential food, as it is in some cases of diabetes. I am therefore sorry to see that the permission to prescribe it under special circumstances has been withdrawn, and am certain that it will have harmful consequences.—I am, etc.,

London, W., March 31st.

P. J. CAMMIDGE.

GENERAL ANALGESIA BY ORAL ADMINISTRATION.

SIR,—In the JOURNAL of March 9th (p. 301) my statement that a "65 per cent. solution of ether in oil will not produce post-anaesthesia dysentery or bloody diarrhoea" is questioned; the writer states that his cases had these symptoms and that consequently he had not used the method between 1913 and 1917. Previous to 1913 I used a 75 per cent. solution. In April, 1915 (*American Journal of Surgery*), I published an article giving the maximum dosage as 8 oz. of a 65 per cent. solution, the usual amount for an adult being 6 oz. If diarrhoea occurs, there is faulty technique somewhere, either the oil and ether is not well shaken up or there has been too many enemas beforehand or unnecessary irrigation afterwards. The 65 per cent. solution is not irritating to the lower bowel. The writer has personally had three anaesthetics—two nitrous oxide and one colonic, and decidedly prefers the latter. The article on oral analgesia is a preliminary statement. The technique will undoubtedly be modified. But all of the anaesthetics are safer in the analgesic stage, as in this stage you are separated from the danger zone by "anaesthesia"; oral (ether) analgesia is safer than nitrous oxide and oxygen anaesthesia, even when given under the most auspicious circumstances. Subcutaneous ether-oil analgesia has been successfully used since the article referred to was published, and will unquestionably be used in the laboratory in preference to inhalation anaesthesia, but oral analgesia is preferable, and in conjunction with morphine will enable the ambulance surgeon to do more for his patients than heretofore. By using the most powerful analgesic—morphine—in conjunction with the analgesic qualities of ether (orally) and nitrous oxide (by inhalation) we have a combination that approaches the ideal.—I am, etc.,

March 13th.

JAMES T. GWATHMEY,
Captain M.R.C., U.S.A.

MEDICAL REINFORCEMENTS FOR THE WESTERN FRONT.

SIR,—In the JOURNAL of March 30th, p. 375, your appeal to medical men to offer their services during the present emergency is certainly very touching, and will meet with the full sympathy of the whole profession. It is not, however, likely to meet with its full support unless some means are adopted for safeguarding the interests of those who are already serving. It would be a serious matter for a man of 50 years of age whose practice is his living to join the army, and have only to look forward to the declaration of peace as the time when he will have to start a fresh practice. As matters stand at present this could be his only fate, judging by what has happened to the majority of the men who have already joined. Men of military age have hitherto chiefly been affected, and in most cases after the war will still be young enough to start a new practice. With the older men it will be different, and I consider it would be a cruel return for their generous patriotism to accept their offers of voluntary military service.

¹ *The Faeces of Children and Adults*, p. 467.

Surely it is not too much to ask for at least the same protection as business men now get—namely, "that no new business, or trade, or shop be allowed to be opened during the war"; and I believe it is the duty of our Association to do all it can for the protection of its members. I would suggest that during the war no one be allowed to start a medical practice without a special permit from the Ministry of National Service, and that this permit be not granted without the sanction of the local Division of the British Medical Association of the area in which the proposed practice is situated.

As a class the medical profession is loyal and patriotic, and if their interests were as far as possible safeguarded, your appeal would meet with a hearty response from its members. Your appeal is undoubtedly urgent, but not more so than the present matter, which, indeed, should have prefaced it. If the Association will get this promptly carried out it will be doing a real service to the medical men already in the army as well as giving some encouragement to those who are about to join.—I am, etc.,

Glyn Neath, Glamorganshire, April 2nd.

S. McCURE.

MEDICAL OFFICERS OF RESERVE BATTALIONS.

SIR,—It is a surprise to me that even now, when our armies are in great need of medical officers, the time of so many men should still be wasted in this country in the Reserve battalions which do not proceed to the front, but supply drafts. Surely one medical officer could easily find time to act for two battalions instead of one, and yet be less heavily worked than most of the civilian medical men. I feel quite sure that a very short experience would prove the truth of this, and it surprises me that the Central Medical War Committee does not press this point on the War Office.

Any further depletion of medical men must act injuriously, not only on civilians, but also on the health of those members of our profession who are striving day and night to carry on their work; and this loss of health will still further increase the dearth of medical men left to attend the needs of the civilian population.—I am, etc.,

P. L. GRUSEPPI, M.D.Lond., F.R.C.S.

Felixstowe, April 2nd.

PRIMARY SUTURE OF WOUNDS AT THE FRONT IN FRANCE.

SIR,—Will you kindly allow me to draw attention to a printer's error in your report of my address on primary suture?

I am made to say: "It is not clear that delay in reaching a casualty clearing station may be unavoidable." This should read: "Is it not clear that delay in reaching a casualty clearing station may be unavoidable?"—I am, etc.,

March 25th.

ANTHONY BOWLBY.

THE PULSE-PRESSURE TEST BEFORE OPERATIONS.

SIR,—Just forty years ago in the Edinburgh Infirmary I took pulse tracings during operations. I possess one set of tracings now. They show that when the first incision was made, when the thigh was sawn through, and when each nerve in the flap was cut short, a marked fall in the pressure occurred.—I am, etc.,

London, E.C., March 26th.

A. OCHER WARD.

IN four of the universities of Switzerland the official language is French and in three it is German. Although there is a large Italian-speaking population there has hitherto been no university in which Italian is the official language. Some time ago a wealthy inhabitant of Ticino, Signor Romeo Manzoni, bequeathed the whole of his fortune to the government of the canton for the foundation of an Italian-speaking university. His example was followed by a number of other benefactors and a fund of several millions of francs has been collected. The authorities of Ticino have taken the first steps towards the fulfilment of Signor Manzoni's wish by founding a superior school of Italian culture in Ticino. It is divided into several sections which are intended to form the nucleus of a university.

Obituary.

WE regret to record the death of Mr. R. H. B. NICHOLSON, consulting surgeon to the Hull Royal Infirmary. He was the son of a medical practitioner in Hull, and spent the whole of his life in that city. He received his medical education at the Hull and East Riding Medical School, where he held the appointment of demonstrator of anatomy. He took the diplomas of M.R.C.S.Eng. and L.S.A. in 1862. He became assistant surgeon to the infirmary in 1876, surgeon in 1886, and consulting surgeon in 1901. From an early date he took a great interest in the affairs of the British Medical Association, was a member of the Committee of Council, and after the reconstitution in 1883 was for many years a member of the Central Council, and served on numerous committees, including the Parliamentary Bills Committee and the Journal and Finance Committee. He did not write much, but contributed several papers on clinical surgery to our columns. He took an active part in establishing the Jubilee Nurses' Home, and had been chairman of its executive committee for many years. He was also surgeon to the Lying-in Charity and to the Withernsea Convalescent Home. He was one of the pioneers of sanitation in the city, and in association with Mr. J. A. Spender, then editor of the *Eastern Morning News*, founded the Hull Sanitary Association, which stimulated the corporation to action. He also took a leading part in promoting improvements in housing, and in these ways contributed much to bring about the present healthy state of Hull. Mr. Nicholson was a man of handsome presence and genial manners, and his kindness of heart endeared him to many, including a large number of members of the Association, who for many years were accustomed to meet him at every annual meeting. He leaves a widow and three sons, one of whom, Mr. Guy Berners Nicholson, assistant surgeon to the Hull Royal Infirmary, holds a temporary commission as captain in the R.A.M.C., and is serving in France.

DR. KENNETH SCOTT, who died on February 19th after an operation for appendicitis, was the only son of Mr. Thomas Graham Scott, of Edinburgh, and was born at Morton Bingley, Yorkshire. He was educated at the Edinburgh Academy, at the University of Edinburgh, and at King's College, London. He took the diploma of M.R.C.S. in 1887, and graduated M.B., C.M. Edin. in the same year with honours. Two years later he took the F.R.C.S. Edin., and was appointed lecturer in ophthalmology at the Egyptian Government Medical School, Cairo, and ophthalmic surgeon to the Kasr-el-Ainy Hospital. These posts he held for ten years, and from 1900 to 1906 he was honorary secretary of the Cairo Blind School, of which he was the organizer. On relinquishing his Egyptian appointments, he started in ophthalmological practice in London, and from 1907 to 1909 was lecturer on ophthalmology at the West London Post-Graduate College. He was also appointed consulting ophthalmic surgeon to St. Mary's Hospital for Women and Children, and on the outbreak of war became medical administrator of the City of London Red Cross Hospital. Dr. Scott made few contributions to medical literature, but a paper read before the Egyptian Medical Congress in 1902 on exact methods of visual examination, showed the practical side of his mind, and the tendency which led to his future success. After settling in London he rapidly attained a practice which during the few years before his death was almost greater than the strength of one man could manage. His health was not good, but his devotion to his work, and the determination never to allow his ideal of exactitude to be lowered enabled him to face with success his laborious life. He was a man of charming manners, a delightful colleague, and held in very high estimation both by his professional brothers and his patients.

DR. GEORGE BELBEN FLUX died in the Royal Free Hospital, London, on March 18th. He was educated at King's College Hospital, and took the diploma of L.S.A. in 1887 and those of M.R.C.S. and L.R.C.P. Lond. in 1888. He took the degree of M.D. Brux. in the same year and

the M.D.Dnrh. in 1904. After acting as resident medical assistant at Nottingham General Hospital, he settled in London. He became anaesthetist to the Great Northern Central Hospital and to the National Dental Hospital, and afterwards to the British Lying-in Hospital and King's College Hospital. He had contributed many articles on anaesthetics to the medical journals. He took a temporary commission in the R.A.M.C. in April, 1917, but was invalided out in the following December.

DR. GEORGE WILLIAM SHIPMAN of Grantham, one of the best known medical practitioners in Lincolnshire, died on March 24th, at the age of 70. After studying medicine at Guy's Hospital, he obtained the diplomas M.R.C.S., L.R.C.P. in 1869, and soon afterwards joined his father in practice at Grantham, where he took for many years a leading part in public life, holding the office of mayor of the borough and J.P. for the county. For more than thirty years he served as medical officer to the Lincolnshire Regiment of Militia, and retired with the rank of surgeon-lieutenant-colonel in 1900. Dr. Shipman took an active share in founding the Grantham Hospital, and served as surgeon for twenty-six years. He was the first chairman of the Kesteven Division of the British Medical Association, first chairman of the Grantham Medical Society, and a former president of the Lincolnshire Medical Benevolent Society. His loss is deeply felt by a wide circle of colleagues, patients, and friends.

Universities and Colleges.

UNIVERSITY OF EDINBURGH.

THE following candidates have been approved at the examination indicated:

FINAL M.B., CH.B.—Eva M. Clark, H. R. Goldberg, W. A. Gray, Martha L. Hamilton, W. G. Hughes, G. Lange, D. O. Macdonald, H. B. Mackenzie, A. R. C. McKerrow, J. S. Mann, D. J. Micah, J. C. Morris, Anne O. Roberts, G. M. S. Smith.

UNIVERSITY OF DURHAM.

THE following candidates have been approved at the examination indicated:

THIRD M.B. (*Materia Medica, Pharmacology, and Pharmacy; Public Health; Medical Jurisprudence; Pathology and Elementary Bacteriology*).—J. R. Hnches, Sujana Raj Chatterji, Nan Coxon, L. W. Hearn, J. Hetherington, R. Sanderson, Habib Toma.

* Second class honours.

UNIVERSITY OF MANCHESTER.

THE following candidates have been approved at the examination indicated:

THIRD M.B., CH.B. (*General Pathology and Morbid Anatomy*).—May Ashburner, Mary E. Boulton, Mary S. Jones, J. F. O'Grady, E. Figgott, A. el H. Sadek.

UNIVERSITY OF DUBLIN.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., PART I.—*Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene, Pathology*: *J. H. Coolican, *W. A. Byrre, E. Counihan, N. Long, A. R. Aldin, W. J. Hogan, J. T. Myrhardt, J. W. Scharff, †D. S. Prentice, †G. H. Keller.

FINAL M.B., B.CH., B.A.O., PART II.—*Medicine*: *H. L. Parker, V. M. Syngé, J. O. Fouché, E. E. Rollins, R. M. D. Devereux, J. B. McGrahan, P. A. Dormer, E. F. Wilson, J. M. Hill, T. H. R. McKiernan, F. A. McHugh. *Surgery*: T. M. Bentley, L. Alberini, F. Gill, A. L. Gregg, W. L. Young, J. G. Bird, R. W. Nesbitt, F. A. McHugh. *Midwifery*: W. F. McConnell, W. Sweetnam, E. F. Wilson, J. B. McGrahan, J. W. Scharff, D. S. Prentice, R. B. N. Smartt, W. A. Shannon, D. McElwee, B. D. Merrin, F. A. McHugh.

D.P.H., PART I.—R. A. Keane.

* High marks.

† Pathology completing examination.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examination indicated:

FINAL PROFESSIONAL.—W. Evans, C. K. T. Hewson, P. J. O'Connell, M. M. Price, P. K. I. Ryan, J. C. Smyth, J. G. Thornton.

Medical News.

THE Admiralty has under consideration a proposal to use Larbert Asylum, near Glasgow, for a naval hospital. The number of sick and wounded it would accommodate is about twelve hundred.

THE Colonial Office has issued the twentieth edition of a leaflet (No. 678) giving information of a general character for the use of candidates for appointments on the West African Medical Staff.

THE first number of a new journal devoted to the interests of the (United States) Indian Medical Service was published recently. Its object is to raise the service to the level of the Army, Navy, and Public Health Services.

PROFESSOR S. G. SHATTOCK, F.R.S., will give three demonstrations during April at the Royal College of Surgeons of England. On April 8th, on foreign bodies; on April 15th, on necrosis; on April 22nd, on malignant tumours. The demonstrations, which will be given at 5 p.m. each day, are open to medical students and practitioners, and also to first-aid and ambulance students.

THE Röntgen Society has recently founded an annual lecture in memory of its first President, the late Professor Silvanus P. Thompson. The first will be delivered by Professor Sir Ernest Rutherford, F.R.S., at a meeting of the society, at Burlington House, on Tuesday next, at 8 p.m. Cards of admission can be obtained from the honorary secretary, Dr. S. Russ, Middlesex Hospital, London, W. 1.

MR. RAYMOND JOHNSON, surgeon to University College Hospital, in seconding a motion for the adoption of the report at the annual meeting, drew particular attention to the good work done during the year in the child welfare section of the hospital. He mentioned also that 250 beds had been assigned for sick and wounded soldiers and sailors. At this meeting two ladies, H.H. Princess Marie Louise and Lady Owen Philipps, were elected members of the General Committee.

THE Air Ministry has announced in the *London Gazette* that all officers serving with the Royal Naval Air Service and Royal Flying Corps on March 31st, 1918, or in connexion with those services, with certain exceptions, are granted temporary commissions in the Royal Air Force with effect from April 1st, 1918. The specified exceptions include medical officers. It is understood that these will be seconded to the Royal Air Force from the Royal Naval Medical Service and the Royal Army Medical Corps.

IN its annual report, recently presented to the State Legislature, the New York State Hospital Commission recommends the adoption of vigorous measures for the prevention of mental disease. The insane cost the State £1,676,400 in 1917, and the Commission expresses the opinion that one-half of the cases are preventable. The measures recommended are: the checking of alcoholism and syphilis, better instruction of the public in mental hygiene, the suppression of extreme poverty, and extension of the out-patient department of State hospitals with more free clinics for mental and nervous disorders and "field agents" to look after incipient and convalescent cases.

THIRTY cases of luxation and avulsion of the eyeball during birth have been published. In four instances the labour was natural, in two the labour was difficult, and in two the orbit was mistaken for the rectum and the eye dislocated by the finger of the accoucheur. All four eyes were lost. In the remainder of the cases the labour was instrumental, and the eye was displaced by the forceps. In two only was the eye replaced with preservation of vision. In one of these the eye was enucleated by the finger of the midwife, who was under the impression that she was dealing with a breech presentation and exploring the anus. H. Friedenwald had recorded another case in the *American Journal of Ophthalmology*, vol. i, No. 1. The left eyeball was completely luxated by the blade of the forceps and the lids were closed behind the eye. An incision was made at the outer canthus and the eye replaced. Two years later the eye was healthy and had good vision. In a number of cases the infants have died from the severity of the head injuries, and many eyes which have been replaced have been lost from panophthalmitis. When reposition is considered possible, it is necessary to remove any fragments of bone from fractures of the orbit, for which purpose Kroenlein's operation may be necessary. Canthotomy is nearly always called for. It has been held that no blame attaches to the obstetrician when the accident results from the forceps.

Letters, Notes, and Answers.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

Authors desiring reprints of their articles published in the *BRITISH MEDICAL JOURNAL* are requested to communicate with the Office, 429, Strand, W.C.2, on receipt of proof.

The telegraphic addresses of the *BRITISH MEDICAL ASSOCIATION* and *JOURNAL* are:

1. EDITOR of the *BRITISH MEDICAL JOURNAL*, *Aitology*, Westrand, London; telephone, 2631, Gerrard.
 2. FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate*, Westrand, London; telephone, 2630, Gerrard.
 3. MEDICAL SECRETARY, *Medisecra*, Westrand, London; telephone, 2634, Gerrard. The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin.
- The address of the Central Medical War Committee for England and Wales is 429, Strand, London, W.C.2; that of the Reference Committee of the Royal Colleges in London is the Examination Hall, 8, Queen Square, Bloomsbury, W.C.1; and that of the Scottish Medical Service Emergency Committee is Royal College of Physicians, Edinburgh.

LETTERS, NOTES, ETC.

THE following appointment for certifying factory surgeon is vacant: Dudley (Worcester).

DOUBTFUL WATER.

IN dealing on a small scale in an emergency with doubtful water by the addition of a solution of chloride of lime, Schell and Parsy recommend, in order to get rid of the excess of hydrochlorite shown by the starch test, that the water should be stirred with a packet of iron wire. Peroxide of iron is formed and is deposited; in about half an hour the water has lost any disagreeable taste due to the chlorine.

RECORDS OF PHYSICAL TREATMENT.

THE War Disablement Committee of the Royal Society of Medicine (Section of Balneology) has resolved to place at the disposal of all practitioners making use of physical treatment for disabled soldiers cards for recording results of such treatment, including baths and electricity, provided they are ultimately returned filled up. A collection of the cards is being made from spas and health resorts to form the basis of a special chapter in the medical history of the war. Cards can be obtained from Messrs. Adlard and Son, 23, Bartholomew Close, E.C., price £2 per thousand.

SANATORIUM TREATMENT OF THE TUBERCULOUS SOLDIER.

DR. J. HORNE WILSON (London, W., late Captain R.A.M.C.), writes with reference to recent correspondence as to the tuberculous soldier: It is probably true, as Dr. Camac Wilkinson states, that not even 10 per cent. of the cases can be benefited by sanatorium treatment, and therefore other methods must be tried which hold out more hope than the domiciliary treatment hitherto offered to the 90 per cent. remnant. I agree that early diagnosis with tuberculin, properly interpreted, would lead to prompt treatment of early cases before tubercle bacilli appeared in the sputum, and it is my experience and opinion that tuberculin in its various forms offers a solution of the difficulty in a large percentage of the cases, and ought at least be given a fair trial. Such a method rarely necessitates loss of employment by the patient, and from an economic point of view the cost to the country would be reduced to a minimum.

TREATMENT OF MENINGITIS.

MRS. Fysh, M.B.Lond. (Dryhurst, Tonbridge), writes to recommend the following treatment of meningitis: As soon as the diagnosis is made, shave the head and paint it all over with tincture of iodine. Repeat the painting daily, or every other day, as the skin can bear it. Keep the bowels acting with small doses of calomel when required. Give a diet carefully arranged so as to spare the digestive organs as much as possible—in infants making the food, of course, more dilute than in health, and using it partially predigested. Combine with these things tepid sponging regularly every six hours; this is a most important part of the treatment. By the above method I was able to save three cases out of four during the last year I held the post of medical officer in charge of the Lady Havelock Hospital in Colombo.

BARLEY BREAD IN ANTIQUITY.

ACCORDING to Pliny, "barley (husked) was the most ancient meat in old times," and this statement seems to be borne out by the fact that three varieties (*Hordeum distichum*, *H. hexastichum densum*, and *H. hexastichum sanctum*) have been found in lake dwellings in Switzerland in deposits belonging to the Stone Age. Athenian athletes trained on barley; it was the ordinary food of gladiators, who, from the allowance of the grain made to them, were called *hordearii* (barley men). Of barley bread Pliny says, that "though so much used of our forefathers in old time, the posterity that lived after found to be sought and condemned it: in such sort as they allowed it for provender only to feed their beasts and cattle with" (*Plinius Natural History*, Bk. 18, Philemon

Holland's Translation). So much was barley bread disliked and despised by the Romans that it was issued as a ration by way of punishment to soldiers who had misconducted themselves before the enemy. Plutarch tells us that when some legions ran away at the battle of Cannasium the Pro-Consul Marcellus as a part of their punishment "appointed they should give those that first turned their backs to Hannibal barley for wheat." Livy says the same penalty was inflicted on cohorts which lost their standards, for it was regarded as a great disgrace to be given this "food of gladiators." According to Suetonius, Caesar Octavius, who was a strict disciplinarian, revived this old punishment for cowardice. Though in the Gospel of St. John (vi, 9) it is recorded that Christ fed the multitude which followed him on five barley loaves and two small fishes, there is evidence that the Jews looked upon barley bread as unfit for human food. In an anecdote quoted from the Talmud by Dean Farrar in his *Life of Christ* it is related that when Johanan said, "There is an excellent barley harvest," the answer he got was, "Tell that to horses and asses."

BOTHRIOCEPHALUS LATUS IN IRELAND.

DR. O'FARRELL reported to a recent meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland a second case of *Bothriocephalus latus*. His first (*BRITISH MEDICAL JOURNAL*, 1916, vol. i, p. 309) occurred in a man who resided on the river Shannon. The new case was in a young woman who resided about fifteen miles higher up the same river.

THE METRIC SYSTEM IN DISPENSING.

DR. KEITH ROBERTSON (Greenock) writes: Dr. Sydney Whitaker, in your issue of February 23rd, 1918, p. 248, makes a plea for uniformity in the use of metric symbols. Using the metric system entirely in prescribing, as I now do, it seems to me that to avoid mistakes and ambiguity, and to enable one easily to memorize a dose, it would be best to deal in grams and millilitres only, and decimals of these. To put down 6 deg. instead of 0.6 gm. is to give the brain unnecessary work in mental arithmetic. A decigram should always be put down as 0.1 gm., a centimil. as 0.01 mil., and so on. Further, it would be well if we dropped the gm. or mil. altogether, and wrote simply 0.03 for three centigrams or centimils., according to whether we were dealing with solids or liquids, using the definite designation only where there might be doubt. Dr. Whitaker's prescription would be written thus:

R Vin. colchici...	1
Mag. carb. pond.	0.6
Mag. sulph.	1
Aq. menth. pip.	ad 30

When our dispensers get measures, weights, and bottles to suit, we will be in a still better position, and the work will be easier for them. For instance, I might write a prescription such as the above, only instead of aq. menth. pip. ad 30 mil., make it ad 20 mil. (or 10 if you like) and direct ten or twenty doses to be sent. For ten doses the dispenser simply removes the decimal point one cipher to the right; for twenty he does the same and multiplies by 2, then dispenses in a 200 or 400 mil. bottle. If then the patient is supplied with a metric medicine measure, the dosage is correct; the uncertainty of "tablespoon" quantities is done away with, and education in the metric measures is of a practical kind.

MILITARY HOSPITAL SERVICE IN THE AMERICAN REVOLUTION.

THE first plan for the organization of a military hospital service during the American Revolution was drawn up by Dr. William Shippen of Philadelphia and transmitted to Congress on February 14th, 1777. Besides director-generals and assistants for each of the northern, middle, and southern districts, provision was made for an apothecary-general, "whose duty it is to receive, prepare and deliver medicines and other articles of his department to the Hospital and ye Army as shall be ordered by ye Director General" and "for Apothecary and Mates to obey ye Apothecary General." The *New York Medical Journal* of February 23rd, which is our authority for these statements, states that Congress has now before it three bills providing for the organization of a pharmaceutical corps in the medical department, and the Surgeon-General has appointed a committee to consider the proposal. In Dr. Shippen's plan provision was made for one nurse for every fifteen sick and a matron to every hundred.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Seven lines and under	0 6 0
Each additional line	0 0 9
Whole single column	4 0 0
Whole page	12 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

NOTE.—It is against the rules of the Post Office to receive *poste restante* letters addressed either in initials or numbers.

Observations

ON

THE NATURE AND SYMPTOMS OF CARDIAC
INFECTION IN CHILDHOOD.

BY

F. J. POYNTON, M.D., F.R.C.P.LOND.,

PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL; SENIOR PHYSICIAN TO
OUT-PATIENTS, THE HOSPITAL FOR SICK CHILDREN,
GREAT ORMOND STREET.

II.—RHEUMATIC HEART DISEASE.*

First Attacks of Rheumatism in Childhood.

THESE bring us to the threshold of the early development of organic disease. Among such cases we find all grades of severity, from those—fortunately rare—which prove rapidly fatal, and in which the infective element reaches its acme of intensity, to those which are so transient and vague that we are left doubtful of their significance. From a study of the latter we realize that a considerable number elude discovery by parents and doctors, and that as a result the early detection of cardiac affections can be but a relative accomplishment, the accuracy of which will only be increased by continual improvement in the education of the public and in our clinical methods.

It is here that a general idea of the relative frequency of the well recognized manifestations of the disease becomes of some practical importance, and the following figures, based upon 524 examples which I believe to be first attacks, may be of service. These figures, however, can only be of relative value, for the proof that an attack was actually the first is often difficult.

When these children (all under twelve years of age) were first seen at the hospital the following conditions were present:

Heart disease	In	293
Chorea	"	268
Arthritis and arthritic pains	"	267
Sore throats	"	147
Nervous manifestations other than chorea	"	80
Anæmia	"	78
Abdominal symptoms	"	52
Cutaneous manifestations	"	39
General wasting	"	39
Nodules	"	22
Epileptaxis	"	8
Nephritis	"	2

Two important groups may be recognized:

1. Cases with sore throat, arthritis, and morbus cordis.
2. Cases with chorea and morbus cordis.

For reasons that I have given in *Researches upon Rheumatism* I have included all cases of chorea as rheumatic in origin.

The sex incidence was as follows:

Females	346
Males	169

In 9 the sex was overlooked.

The percentages in this series were approximately

Females	69
Males	33

As nearly as possible 2 to 1.

Age incidence in 364 cases:

One year and under	...	3	6-7	38
1-2	...	4	7-8	63
2-3	...	13	8-9	37
3-4	...	25	9-10	45
4-5	...	38	10-11	37
5-6	...	40	11-12	21

CLASSIFICATION OF THE CHIEF LESIONS OF RHEUMATIC
HEART DISEASE.

I think the clearest and most instructive method of approaching the subject is to commence with the earliest and often the least severe cardiac lesion—acute dilatation. This is an essential feature in the history of rheumatic cardiac affections, and must be clearly recognized. Then will come for description the most severe and most characteristic event—an acutely fatal carditis in a first attack. From these latter cases we learn the true

meaning of a cardiac infection. Next will follow the three cardinal lesions of the textbooks—pericarditis, endocarditis, and myocarditis—which lead to the consideration of recurrent carditis and the final stages of infective carditis.

Whatever classification is adopted, the element of carditis will be found frequently complicating the individual lesions, but I shall endeavour to avoid a troublesome repetition of symptoms and consider the subject only with the view of illustrating special features of the rheumatic infection.

ACUTE DILATATION.

There are all grades in the severity of acute dilatation. In very rare cases it may prove fatal without endocardial or pericardial involvement. Far more frequently it occurs with some mitral endocarditis. Again, it is the chief cause of cardiac failure in recurrent attacks of carditis. Lastly, there is a large group in which the dilatation either is not severe and may be recovered from rapidly, or may be slow in course and intractable.

We are concerned here with the mild acute cases recovering rapidly. The more severe and the chronic cases will be considered later.

When it is recognized that some degree of dilatation may be the only cardiac lesion, and also that it complicates all the more severe rheumatic cardiac injuries, it will be evident that this is not only the earliest clinical evidence we possess of rheumatic heart disease, but also the most frequent.

I advocate the value of making careful outlines of the deep cardiac dullness in this lesion and of tracing these outlines on to paper for future reference. Each outline should have fixed points, such as the left nipple and mid-sternum, marked on it, and should be completed with the date and a brief synopsis of the symptoms and signs. Though I am no believer in a rigid dependence upon cardiac percussion it is remarkable how accurate the results become by persevering with this rather laborious method. From such an experience we learn not only to appreciate the reality of simple dilatation but also to detect the part it takes in acute pericarditis, and in the exacerbations of rheumatism in hearts already injured by the disease. Another point we learn is the remarkable rapidity with which dilatation sometimes occurs even when a child has been in bed for some days. Without special care this may be easily overlooked, but it is quite in accord with other events that may happen to a rheumatic child while resting in hospital. For example, a sore throat may suddenly develop, or chorea commence, or an arthritis show itself. These outbursts of infection constitute one of the peculiarities of the disease, and they suggest the sudden influx of a fresh wave of infection after the earlier one has been dealt with by the tissue cells.

*The Signs and Symptoms of Acute Dilatation of
the Heart of Mild Degree.*

The chief signs of acute dilatation of mild degree are not difficult to ascertain or to remember when once they have been thoroughly studied, and may be summarized as follows:

If the child is leading its usual life there will be found shortness of breath, pallor, and palpitation, and there may even be a fainting attack. The pulse is quickened, and easily compressible.

The impulse of the heart is enfeebled and the cardiac dullness reaches to or beyond the left nipple line, and may be increased to the right. At the impulse the first sound is shortened, and at the pulmonary base the second sound is accentuated and may be reduplicated. Over the mitral area a soft systolic bruit may be audible, which is often at its maximum just internal to the impulse, and is not conducted plainly toward the left axilla. There will probably be a slight rise in the temperature.

From the above description it is apparent that it may be far from easy to decide whether in any given case there is together with the dilatation some endocarditis of the mitral valve. A question I have had put to me is how to distinguish these two lesions, and the answer, though not difficult to give, is necessarily incomplete.

If there is mitral endocarditis of some severity the apical murmur is conducted towards the axilla, and even if not permanent will not disappear for many months, and long after the soft murmur of a dilatation will have vanished. Further, there is usually evidence of hypertrophy of the left ventricle supervening upon the dilatation. If the endocarditis is slight

* The first article was printed in the JOURNAL of March 2nd, 1918.

the murmur will nevertheless persist after all evidence of dilatation has disappeared. There remain a certain number of cases in which the dilatation is slow in recovery, and also some others in which in all probability a valvular murmur disappears with unusual rapidity, and then we may be in doubt. The uncertainty in the latter case is not in reality of practical importance, for if the murmur disappears and the heart becomes sound we can but be satisfied. If, however, the dilatation is more stubborn than usual there will be the signs of myocardial feebleness, and for a considerable time we must remain in doubt as to whether or not an endocarditis is responsible for this delay.

It is clear, then, that a satisfactory answer to the question sometimes requires time and repeated observation before it can be given.

There is no doubt, I think, that the rapid development of acute dilatation accounts for some of the cases in childhood in which, after a slight arthritis, the patient has been allowed to return quickly to ordinary life, and has then become suddenly short of breath or has collapsed with a syncopal attack. A thorough understanding of this possibility will serve as an added warning to watch carefully the early days of what may seem a very mild attack of rheumatism.

FATAL FIRST ATTACKS OF CARDITIS.

From the least severe of the rheumatic cardiac lesions—acute dilatation of slight degree—I pass now to the most severe, which brings into prominence the part taken by infective processes in human heart disease, and illustrates how completely they may destroy all attempts at recovery of the mechanical balance of the circulation. In such cases we must expect to find symptoms of great severity and of an unusual nature—for example, shivering attacks, vomiting, and diarrhoea, great muscular prostration and extreme illness; and we are also impressed by the rapid progress made by the cardiac disease. Thus pain over the precordium will be swiftly followed by severe dilatation and cardiac excitement, pericarditis will rapidly become general, and endocarditis appear. In a week or two the heart is irreparably damaged. It is not, however, the pericarditis or valvular disease that alarms us most, but the general cardiac infection and the failure of the general vitality from the virulence of the disease.

These fatal first attacks are rare—and they are more often met with in young children or in those with a strong hereditary tendency to rheumatism.

I would draw particular attention here to the answer that these severe cases gives to those who hold that rheumatism is an attenuated pyaemia. A study of them must, I think, convince us that the illness is of a deadly virulence, and yet, as the necropsies prove, never approaches to the character of a pyaemia. The poisons may be chemically allied to those of pyaemia, but they certainly are as special in their action as the poisons of any other specific disease.

The fifteen cases upon which these observations are chiefly based fall into two main groups:

- (a) Fulminating cases of acute carditis.
- (b) Insidious cases in fragile children of feeble constitution.

In this latter group the disease is deceptively quiet in its onset, but none the less deadly. The four following examples well illustrate these fatal forms of carditis—the first three the fulminating group, the last the asthenic.

Example 1.

A boy under 5 years of age, with a rheumatic history on the father's side, was seized with general illness a week before admission to hospital. At the outset he was prostrated with vomiting and diarrhoea and pains all over the body, and on admission he looked very pale and ill. There was arthritis of both knees, and there was great dilatation of the heart with a rapid pulse (140 per minute), and a systolic mitral murmur. Two days later general pericarditis was discovered, and broncho-pneumonia developed. The temperature ranged between 103° and 100° F. The course was rapidly downhill, the liver became palpable, and slight oedema appeared. Restlessness and a running pulse, with some albumin in a scanty urine, followed, and death occurred fourteen days after admission.

The necropsy showed recent pericarditis, great dilatation, and early mitral endocarditis. The diplococcus was isolated from the pericardial, pleural, and arthritic exudations, and from the cerebro-spinal fluid.

Example 2.

A girl, aged 3½ years, was admitted to hospital very ill and with signs of severe cardiac disease. Her father had suffered

from rheumatic fever and a sister had died of the same disease. Four weeks before admission, after developing a sore throat she became generally ill, with pains all over the body and swelling of the hands and ankles.

In hospital sour perspirations were noticed with high fever; dilatation, general pericarditis, and mitral endocarditis followed. Later nodules appeared together with the usual signs of cardiac failure. Finally all food was refused, and the child died after lingering for five weeks.

Example 3.

A boy, aged 7½ years, had suffered ten days before admission with general malaise, diarrhoea, sleeplessness, and cough, rapidly followed by arthritis of the ankles, fingers, toe-joints, and erythema multiforme. The pain disappeared and three days later he was allowed to get up. The same night he became delirious. When admitted to hospital there was severe carditis and he died six days later of syncope.

The necropsy showed a large pericardial effusion with simple aortic and malignant mitral endocarditis. Reference will be made later to this most remarkable case.

The next example illustrates the asthenic form of fatal carditis:

Example 4.

A girl, aged 4½ years, who was pale, fat, and flabby, had suffered for some weeks before admission from indefinite illness. The chief early symptoms were muscular feebleness and general prostration, with progressive pallor and loss of appetite. Then there developed a slight but definite chorea. When admitted the child was very ill and the pulse rapid (130), the heart was greatly dilated and the sounds faint with a soft systolic apical murmur. The next day general pericardial friction became audible. The temperature ranged around 100° F., and the extremities were cold. There was no sign of rallying to treatment and four days later she died from cardiac failure, the temperature rising in the last twenty-four hours to 104° F.

The necropsy showed recent universal pericardial adhesions, great dilatation, mitral and tricuspid endocarditis, plastic pleurisy on both sides and an ante-mortem thrombus in the left internal jugular vein.

These cases give a general indication of the clinical course of this most fatal form of rheumatic heart disease. We do not see cyanosis and distended jugular veins. There is no pronounced development of oedema with great enlargement of the liver. The child is more often ashen pale, the liver palpable, and the oedema a mere puffiness of feet and ankles. Death is often sudden from a terminal syncope, and the general appearance one of a severe toxæmia with a high degree of oxygen want.

In cases such as these Dr. Paine and I have demonstrated and isolated the strepto-diplococcus, a result only to be expected from the experience of bacteriologists studying other virulent infections.

RHEUMATIC PERICARDITIS.

The consideration of the rheumatic lesions pericarditis, endocarditis, and myocarditis, apart from carditis, is necessarily artificial, but is essential on account of their individual importance.

Pericarditis is placed first here because of its gravity. It is in general terms a mark of a severe infection, and is repeatedly met with in fatal carditis. One hundred and fifty cases in children under 12 years of age showed at necropsy that the pericardium was adherent wholly or in part in 113 cases, and in only 9 cases was it stated to be healthy. In only 6 cases were more than 3 oz. of fluid recorded in the pericardial sac.

My experience both as a teacher and an examiner has shown me that the student looks upon rheumatic pericarditis as a disease in itself, running through three definite stages: (1) the stage of early inflammation; (2) of pericardial exudation; (3) of resolution.

In the general study of pericarditis such a conception is undoubtedly useful as a finger-post to guide us through the first difficulties of the subject, but it is not a correct or even satisfactory description of the rheumatic form in childhood. It brings the element of effusion into too great prominence, both as an incident in the illness and as a factor in the production of grave symptoms, and places too much emphasis upon mechanical embarrassment of the heart, which in reality takes but little part in rheumatic pericarditis at this age. There seems by this view to be an idea that some mysterious stage of effusion must appear and disappear with the regularity almost of clockwork. But the pathological changes are much more complicated.

We know from experiment that rheumatic inflammation commences within the pericardial tissues and not upon the

surfaces. In severe cases the foci are innumerable; in mild cases they are fewer and may not even damage the surface endothelium. The exudations vary, too, in character with the virulence and stage of the process. The worst cases show haemorrhagic exudations, but more usually they are fibrinoplastic or serofibrinous and seldom very copious. If the process is obstinate and subacute, the changes may be chiefly in the pericardial tissues, where nodular formations may occur and great thickening of the parietal layer follow. The amount of exudation in such a case will be small, if any, and the two diseased layers will become welded together by scar formation between the opposed surfaces. This condition is comparable to that of mitral stenosis.

The morbid process, commencing as it does in local foci, may severely implicate one part only of the pericardium—for example, the posterior—and even when it is termed general there are often left comparatively untouched areas in which subsequently new lesions may arise causing pericardial friction, although at the necropsy the pericardium may appear to have been universally adherent.

In rare cases, again, a large effusion may give rise to special symptoms.

It is evident, then, that our conception of rheumatic pericarditis must be built up on a clinical study of individual cases, and we cannot assume a definite and regular sequence of events.

The practical application of these pathological changes in rheumatic pericarditis to clinical medicine is of great value. In this condition there is often great and sometimes extreme enlargement of the area of precordial dullness; and if we have trained our minds to a rigid adhesion to the three stages of pericarditis we naturally regard this increased area as the result, and further the measure, of effusion. Then naturally we shall regard the feebleness of the heart as the mechanical result of the effusion and be tempted to act upon this reasoning. What, however, is the real truth? It is this: In the vast majority of cases the increased area is the result of acute dilatation (added to, doubtless, in some degree by effusion), the dilatation itself being the result of a carditis. If we rashly thrust a trocar into the area of increased dullness we should probably pierce the heart, as has been done on more than one occasion.

I am convinced that it is a very valuable aid to the physician (for it is no light undertaking to venture upon operative measures in pericarditis) if he realizes that however large the area of cardiac dullness in the rheumatic pericarditis of childhood it is exceptional for this to be the result of a large effusion.

There is another point which, while of lesser importance, must not be lost sight of. Pericarditis is rightly looked upon as a serious lesion, but we must beware of assuming that because pericarditis is *not* present the heart is not seriously damaged. Apart from the great difficulty in detecting some cases of pericarditis there may be occasions upon which it does not occur and yet the heart affection be very severe. These are examples of myocarditis which show the same dilatation and excited action as do the pericardial infections but they lack the clinical sign of friction. Such a heart may be far more seriously injured than one in which there has been general pericardial friction. I have seen, as have others, several cases of general pericarditis in strong children run a rapid and most benign course, and later have failed to detect any fault but a slight mitral leak. This exemplifies a cardinal rule in the study of infective heart disease—that we must be guided by the general results of the injury to the heart and to the patient, and not entirely by clinical terms such as pericarditis or a clinical sign such as pericardial friction.

These three points bear recapitulation:

1. The varying types of pericarditis in rheumatic children.
2. The rarity of large effusions.
3. The dependence of the symptoms upon a concomitant carditis.

Pericarditis, in addition to the evidence it affords of severe infection, brings certain dangers of its own. Pain may be a prominent feature, increased no doubt in many cases by its association with pleurisy, and the supporting power of the pericardium is seriously injured when its tissues are severely inflamed. Doubtless the movements

of the heart are embarrassed when the two surfaces of the pericardium are much roughened, and, though in childhood much effusion is rare, exceptions occur introducing these added difficulties. Very serious results will follow when the inflammatory process has spread through the outer surface of the parietal pericardium and invaded the mediastina, joining here with other inflammatory areas in the pleurae, for when healing occurs the matted tissues around the pericardium become welded to it and in turn to the heart by the internal pericardial adhesions. These complications are occurring at a time when the heart is dilated and the neuro-muscular tissues weakened by the disease. It is these particular results of pericarditis which make it necessary to consider the lesion apart from endocarditis and myocarditis, provided we also remember that these are usually present at the same time and add to the complication.

The chief clinical forms of pericarditis in childhood are:

1. Acute internal pericarditis with some effusion.
2. Acute pericarditis, internal and external, with mediastinitis and pleurisy.
3. Malignant pericarditis.
4. Relapsing cases.

These distinctions are to some extent artificial, but they are of value at the bedside because they illustrate the various courses that this lesion may take.

ACUTE PERICARDITIS.

Every textbook deals fully with the signs and symptoms of this lesion. As a rule the temperature is considerably raised, and there is a general illness with precordial pain, rapidity and feebleness of the pulse, and considerable dilatation.

Delirium appears to me to be very exceptional in childhood, and in some of the few cases I have met with chorea has seemed to me a factor in the mental state.

We rely greatly on pericardial friction for clinching the diagnosis, although we may be practically convinced by the general symptoms and trend of the case, even when friction has not been detected. Yet there are not in all cases of rheumatic pericarditis in childhood great distress and illness. On the contrary, there may be neither, and the physician may well be surprised when in a case of chorea with no apparent distress he discovers on examination of the heart very obvious pericardial friction. In fact, we can never safely forget in the rheumatism of childhood that the heart invariably requires careful physical examination.

Pericardial friction is a very constant sign in rheumatic pericarditis, but I have not expressed this frequency in statistics because it is difficult to obtain accurate figures and they are open to considerable error. In general terms it may be stated that its occurrence is the rule and that the exceptions are either cases of active myocarditis or examples of pericarditis over a localized area on the posterior aspect, and in both instances the problems in treatment are closely akin.

When effusion occurs the cardiac sounds, as a rule, become less audible, and often the friction disappears or diminishes, but this is not constant, and it is well known that a loud pericardial rub may be heard even when there is a large effusion. More frequently the disappearance of the friction is followed shortly by its reappearance. The sound is then harsher and more grating, and is coincident with a general improvement in the child's condition. Clearly now the process of resolution is in progress, the two surfaces of the pericardium have approximated, and the exudation upon their surfaces has become more viscid.

The sequelae of pericarditis are beyond the scope of this article, but we have to remember that in the convalescence from acute pericarditis, provided there is no gross external adhesion, our attention must be shifted from the pericardium to the damaged myocardium.

Endocarditis is almost invariable, though occasionally we find no evidence of its occurrence. This, however, is so unusual as to suggest that the pericarditis may be the result of some other infection—for example, the tubercular rather than the rheumatic—although I have convinced myself that this event may occur also in the rheumatic form. It does not follow that because endocarditis is present we may at first be able to detect it, for the louder pericardial friction may entirely hide the softer valvular bruit.

The course of an attack of acute pericarditis varies not only in virulence but with the resistance offered by the patient. There are exceptional cases in which the friction disappears in less than a week and the temperature reaching normal remains at this level. The dilatation rapidly subsides and the recovery may reach in three weeks the period of steady convalescence. Eventually recovery may be complete and even the mitral valve may have escaped involvement.

Far more frequently the active period is at least three weeks, during which time the friction may appear, disappear, and again become audible. There are pain and breathlessness with orthopnoea, a rapid pulse and irregular fever.

A close watch must be kept for increasing dilatation, progressive pallor, and increased frequency of the pulse-rate. Vomiting and restlessness are alarming symptoms warning us that the circulation is much enfeebled; a view confirmed by the appearance of slight enlargement of the liver, a scanty sometimes albuminous urine, and some oedema of the lungs. The physical signs over the chest posteriorly are often important. When there is great dilatation or an unusual degree of exudation, pressure upon the left lung and its bronchus will produce a condition of collapse of the lower lobe which may be mistaken for pneumonia or effusion. The note is impaired at the base behind and the breath sounds are intensely tubular at the level of the lower border of the scapula. No crepitations need, however, be detected, and as the condition subsides the breath sounds become at first harsh and finally, in favourable cases, again normal.

It will greatly assist in the realization of this result on the left lung if an opportunity is obtained of seeing a necropsy upon a case of severe pericarditis with great cardiac dilatation. In such hardly any part of the lower lobe of the lung will be visible from the front, for it has been crowded back by pressure into the left axilla, and the condition of collapse will be very evident and the pathological signs produced easily understood.

I have only met with one case in childhood in which there has been an extreme effusion, producing embarrassment of the heart by its bulk and death by syncope. This was the case (No. 3) alluded to under acute carditis, and although operative measures, as the event proved, would have been of no avail, there was no escape from the fact that my interpretation of this case was a mistaken one. In this instance there was fullness of the intercostal spaces on the left side over the precordial area, which should have led to a correct interpretation when coupled with muffling of the cardiac sounds and the extreme distress.

A very remarkable coincidence followed this case in the admission of another child with severe pericarditis, muffling of the sounds, and an extreme area of cardiac dullness mounting as high as the second space on the right side. I was so unsteadied by my previous experience that I seriously considered surgical interference, but was checked by the very grave condition of the patient. The necropsy showed here that there was no fluid in the pericardium but a very much thickened parietal pericardium with recent adhesion to an enormously dilated heart. I record this case here as a warning of the care that is needed before deciding upon paracentesis of the pericardium, and of the extreme value of the guiding rule not to hasten to assume the presence of a large effusion.

ACUTE PERICARDITIS, INTERNAL AND EXTERNAL, WITH MEDIASTINITIS AND PLEURIS.

This group is a dangerous one, for it contains the cases in which the sequelae due to adhesions are the most serious. Here the pain and distress are greater, owing to the concomitant pleurisy. Pleuro-pericardial friction will be heard along the right and left margins of the cardiac dullness, and crepitations may be audible immediately under the stethoscope in the anterior mediastinum. In some cases the inflammation of the serous membrane is more extensive, and the surfaces of the liver and spleen are involved, and we hear the comparatively rare sign of peritoneal friction.

The course is a long one, extending, should the child survive the initial attack, over many weeks. The heart is greatly dilated, and remains so in spite of the greatest care in treatment. Later hypertrophy may develop, and then there may slowly supervene the signs of an adherent pericardium or of multiple serositis. To avoid any confusion by use of the term external pericarditis, I mean by it inflammation of the outer surface of the parietal pericardium.

MALIGNANT PERICARDITIS.

This may give rise to some puzzling signs owing to the thickening of the parietal layer of the pericardium. In some cases at the necropsy this layer may be found a quarter of an inch in thickness, and will be loosely adherent to the visceral pericardium by recent adhesions.

The course is protracted, but when from the first the disease implicates the entire pericardium it runs a disastrous course, which is best exemplified by the following instance:

A boy aged 7 years had a severe attack of carditis in the preceding year, and three weeks before his admission to hospital had suffered from multiple arthritis and precordial pain. His final illness lasted 8½ months. During this time there were repeated nodules, and there was irregular fever reaching to 104° F. From time to time pericardial friction appeared, and faded away only to reappear. He gradually became more anaemic and weaker, and died of cardiac asystole. The necropsy showed great thickening of the pericardium and some recent adhesions; no fluid was present in the sac.

I have termed this a malignant rheumatic pericarditis because it suggests to me a process in the pericardium closely akin to that met with in the endocardium in malignant endocarditis. There is great local change from the micrococcal infection with the formation of nodular masses containing necrotic areas surrounded by greatly swollen and damaged connective tissue. There is also considerable persistent pyrexia. We must not, however, expect to meet with the widespread dissemination of foci of infection that occur in malignant endocarditis, for the pericardium does not bear the same relation to the general circulation as does the injured valve. Numerous infarctions, aneurysms, and such like phenomena will not occur, but the likeness lies in the obstinacy of the infection, the fever, and the severe general symptoms.

RELAPSING CASES.

In the relapsing form we see the link between the preceding and the more usual acute pericarditis. The symptoms may never be severe, but the process advances by a series of local areas of infection, and pericardial friction may be audible at intervals for many weeks. When the rub disappears there is some degree of general improvement, when it reappears there is an exacerbation of the symptoms. The pulse remains rapid and the heart is excited and dilated. Considerable thickening of the pericardium may result, and the heart itself is much damaged by chronic inflammation.

This course is likely to supervene in fragile, weakly patients who have little power of thoroughly destroying infection, and the outlook is gloomy although it may be difficult to realize the gradual sapping of the cardiac power while the child is in bed carefully nursed and guarded.

The thickening of the parietal pericardium, which occurs with the deposit of thick exudation upon the opposed surfaces coupled with the cardiac dilatation, may readily deceive those who are not acquainted with this form of pericarditis. The cardiac sounds are muffled and the area of precordial dullness is greatly enlarged, and may precisely resemble the outline that is met with when there is a large exudation. Further, the interpretation of an x-ray examination needs caution. The report may support the view of a large effusion based upon the outline of the shadow, and yet, as I have confirmed, the necropsy has proved the contrary to be the case.

If we can clearly discern the outline of the heart separated by a lighter area from the outline of the pericardium this interpretation of effusion is justified, but in these particular cases no such distinction between the two outlines will be found. An attempt in such a case to drain the pericardium can only lead to failure and possibly to disaster.

In these instances, in which the pericardium is so much swollen and injured by disease, there is a serious danger of the incomplete healing of the foci, and, with the persistence of lurking infection, of the development of the malignant form of pericarditis.

NOTE.—A kindly critic has directed my attention to two badly expressed sentences in my first article. On p. 250, col. 1, lines 33 and 34, for "small follicular deposits" read "small deposits between the follicle"; line 49, "for internal ear" read "middle ear."

OBSERVATIONS ON SHELL SHOCK AND NEURASTHENIA IN THE HOSPITALS IN THE WESTERN COMMAND.

By ERNEST W. WHITE, M.B.LOND., M.R.C.P.,
HONORARY LIEUT.-COLONEL R.A.M.C.,

CONSULTANT IN MENTAL DISEASES TO THE WESTERN COMMAND;
EMERITUS PROFESSOR OF PSYCHOLOGICAL MEDICINE,
KING'S COLLEGE, LONDON.

SINCE December, 1916, I have been actively engaged, *inter alia*, as inspector of shell shock and neurasthenic patients in the general, sectional, auxiliary, military, Red Cross, and V.A.D. hospitals of the Western Command. The extent of this command may be judged from the fact that it reaches from Gretna Green to Milford Haven, and embraces the Isle of Man, Cumberland, Westmorland, Lancashire, Cheshire, Shropshire, Herefordshire, Monmouthshire, and all Wales. Having examined and taken notes of more than 800 cases of shell shock and neurasthenia in these hospitals, it has occurred to me that my observations thereon might be of interest and of some slight value in the treatment of these diseases.

The symptoms of shell shock have been fully analysed and described by many neurologists, and the painful picture of the acute sufferer drawn by able hands; but while great stress has been laid upon the disorders of the cerebro-spinal system, hardly enough attention seems to have been given to the altered functions of the sympathetic ganglia and nerves. I have been impressed by the large number of these patients with hysterical or pithiatric symptoms. When brought before me several—mostly young men between 19 and 25 years of age—have exhibited intense suffusion of the face, free perspiration, widely dilated pupils, rapid heart's action with weak pulse and cold clammy extremities, terminating in a hysterico-epileptic seizure with marked clonic spasms of comparatively short duration. The fine tremors have continued after the clonic spasms have passed off. I have met with several cases of hyperthyroidism with slight enlargement of the thyroid gland, one of which exhibited nearly all the symptoms of Graves's disease—palpitation, enlargement of thyroid, shortness of breath, anaemia, and protrusion of eyeballs. In one or two cases I have suspected hyperadrenalism from excessive functional activity of the suprarenal bodies under emotion. In these there has been slight cardiac hypertrophy, with rapid pulse and hysterical symptoms.

It is unnecessary for me to describe the coarse and fine tremors of shell shock patients. They may affect the arms and hands, legs, neck, and body generally, but I have seldom observed fine tremor of the tongue in a purely functional case. If this symptom exists it is generally found in the man who has reached or passed maturity and who has been addicted to the abuse of alcohol or excessive smoking. In testing patients for fine tremors I make them face me and extend the arms, one at a time, at right angles to the body and square with it, with the hands vertical and the fingers spread open, the head being turned to the opposite shoulder. Fine tremors are always more marked in the hand which is most used. The coarse tremors are often simulated by the malingerer or skrimshanker; the fine they cannot affect.

I examined a man recently who was called up as a recruit in January last, and who three weeks later, after inoculation, exhibited continuous coarse tremors of the upper extremities until three weeks ago. He had never been exposed to shell shock, or shock of any kind. It appeared to be solely a case of "funk" at "having to do his bit." He had no fine tremors of the hands or exaggerated reflexes. I recommended daily faradism, varied by galvanism if necessary, to the upper extremities. He has steadily improved, and a week ago absented himself from the hospital without leave, to be brought back a day later.

I have seen quite a number with all the tremors of shell shock who have never been near the fighting line, and many who have never been out of the country. Their symptoms have arisen from fright, worry, and nerve tension self-induced. Several of these men were old alcoholics of about 40 years of age who had been called up.

The symptoms of shell shock in wounded soldiers are often latent for a period after the wound is sustained. Hence the man arrives at the base labelled wounded only, and as such is sent to the general hospital on this side. Owing to the pressure on the home general

hospitals after a "push" many patients are quickly passed on to the sectional and auxiliary hospitals, and it is in these the shell shock symptoms are first manifest. The wound heals, but the shell shock symptoms remain. To ensure that such cases are properly treated we early last year gave instructions in the Western Command that these men should be removed as speedily as possible to the special neurasthenic hospital at Maghull. This has necessitated a considerable extension of that hospital, and the equipment of a second neurasthenic hospital in the southern portion of the command is to be undertaken at an early date.

The cases of hysterical or pithiatric paralysis, the hemiplegias, paraplegias, monoplegias, contractures, and men with halting gait and limps have been sent to the special neurasthenic hospital, Maghull, or to the special sectional nerve hospitals for treatment. I have not noted any ties, and I think they are comparatively rare in shell shock cases. The cephalalgias are mostly frontal and intertemporal, occasionally occipital in the hysterico-epileptic cases, never vertical. The pain is worse in the morning and increased by excitement or brain fag. Pains in the lower limbs are more usual than in the upper, and pains in the viscera and spine are not uncommon. A few of my cases have been deaf-mute or mute, a good number have spoken only in whispers, and many stammered or had blurred and hesitating speech. I have not had any patients blind through shock, although some had lost their sight but regained it before they came under my notice. A number suffered from periodic vomiting, and two or three had glycosuria.

The mental symptoms noted have occurred in the following order of frequency: Confusional, melancholic, delusional, stuporose, and maniacal. I have been struck by the relatively few cases of mania to melancholia which have occurred in this war. General paralysis of the insane also has been rarer than I expected. In many patients the memory is impaired for recent events and day to day actions and happenings, and there is a blank in regard to the incidents of their shell shock period. Memory for recent events of daily life, however, improves as the case progresses to recovery. I would here allude to the possibility of "altered character" resulting from shell shock. The moral tone of the individual may be changed for the worse, and this change of character may be out of all proportion to the severity of the original shell shock. With it there may be altered feelings, affections, temper, and habits generally. From the medico-legal standpoint this morbid mental state is very important in regard to responsibility, and must be duly recognized. I have seen such cases during the past twelve months, and no doubt there have been many of them.

TREATMENT.

It is now fully recognized that the various shell shock neuroses are very curable in the early stages, but much more difficult to deal with if allowed to drift, and, moreover, they can only be successfully treated by specially skilled neurologists, who have the entire confidence of the patients. Many letters have appeared in the general and medical press recently condemning the congregating of shell-shock patients and their association for treatment under a common roof. Such statements are misleading and wrong, for if these patients are associated for skilled treatment in a special hospital they are greatly assisted to recovery by contact with those patients whom they see are improving daily, and who will encourage them to persevere in the treatment so as to regain their self-control and self-confidence. That it is bad to congregate shell shock patients with others who are suffering similarly and are not improving through want of special treatment, I readily admit; and the non-improvement of the cases in sectional, auxiliary, and voluntary aid detachment hospitals under excess of sympathy, encouragement of auto-suggestion, and want of special treatment, has, I fear, been the cause of the statements alluded to.

In the early days of the war the treatment of shell shock—the outcome of the terrible explosives now used and the continued mental and physical strain of trench warfare—was not understood, and by some many of the symptoms were attributed to fear. This was soon corrected when it was found that many of the indubitably bravest men fell victims to it. Then came a complete

revulsion of feeling. The terrible picture presented by the acute sufferer appealed most forcibly to the finer sentiments of all, and an excess of sympathy and indulgence followed quickly. The patients were nursed with the tenderest care, surrounded with luxury, and considered in every way. Nerve tonics and sedatives were freely given, and when the milder cases improved somewhat, these patients were sent on sick leave to their friends, who said: "He is very low spirited; we must have a few people in and a merry evening to cheer him up. He wants a little stimulant, whisky or wine. We will take him for a motor ride. He shall go and stay with So-and-So at X (a large town, low-lying and relaxing), and be taken to the theatres and cinemas." All bad for the patient! So he did not improve, and a relapse frequently followed.

Now the treatment which has been found most efficacious is very different. The patients with acute symptoms are kept in bed, but made to get out and walk a few steps every day, when able, and are transferred to the Neurasthenic Hospital for special treatment as soon as possible. In the meantime, if sleepless, they are given medinal, trional, or bromide and chloral at night. Absolute quiet and fresh air (verandah life if weather permits) are essential, and no stimulants can be allowed. These acute cases are mostly treated at the base, at Netley, and in the special nerve hospitals of the command. I have seen patients, however, who have been kept in bed for weeks and weeks, petted and favoured in every way, who made no effort to help themselves, and consequently made no progress whatever. These were speedily moved to other surroundings, for treatment elsewhere.

The milder cases with tremors and those with hysterical or pithiatric, and mild hystero-epileptic symptoms improve under bromide and valerian, nux vomica, arsenic, and other nerve tonics, but environment and habits of life play an even more important part than drugs. Convinced of this I drew up last November the following "rules of health" for these patients, to be specially applicable to those in the sectional, auxiliary, V.A.D. and Red Cross hospitals, and to convalescents on sick leave. These were approved by the Deputy Director of Medical Services and issued.

Rules of Health to be Observed by Shell Shock and Neurasthenic Patients.

1. Live as much as possible in the open air by day and night. Always have a window open at night.
2. Exercise both of body and mind is essential, but it must be carefully regulated and never taken to exhaustion. When the legs tire, sit down. When the head swims or aches and you cannot collect your thoughts, put the book down.
3. Avoid crowded rooms, cinemas, and theatres. Excitement and close rooms are harmful.
4. Avoid all alcoholic stimulants; they are most injurious in shell shock cases, as also is the excessive indulgence in tobacco, especially in the form of the cigarette.
5. Keep early hours. To bed before 10 p.m.
6. Let the meals be regular and the dietary simple, liberal, and highly nutritious. Rest for an hour to an hour and a half after the midday meal.
7. Avoid cold baths until you can get the afterglow. Prolonged hot baths are enervating. Tepid are best.
8. Electricity and massage are of no use, except for wasted muscles or stiffness of joints.*
9. Exercise self-control to re-establish self-confidence by re-education, recognizing all the time that your condition is one which should result in complete recovery.
10. When on leave and your movements are under your own control: (a) Be in the country rather than in a town. (b) Avoid all worry, noise, and excitement, all raided areas, proximity to training camps, and the jar of explosives and gunfire. (c) Never travel by train, motor car, or tram if you can avoid it. (d) Stay at a high altitude where the air is bracing in preference to a low level, where it is generally relaxing. This does not apply to bracing seaside resorts.

Carefully controlled employment of mind and body is most necessary to expedite recovery and divert the patient's thoughts. He must be out of doors whenever the weather permits, engaged in gardening, wood-cutting, and outdoor sports and games, and, when indoors, in workshops, and in taking part in the various amusements of home life. Clear, bracing air is very important. A number of our neurasthenic officers who were not doing at all well in a palatial low-lying residence were moved to a castle at a higher altitude a few miles away, and they improved at

once. Patients moved from large towns to bracing seaside resorts have made similar progress.

For the severe neuralgic headaches we give aspirin and phenacetin, and, to those who have been in Mesopotamia and Salonica, quinine. The man who stammers needs re-education. I tell him to read aloud to himself for half an hour, morning and afternoon; then to read to one or two of his fellow-patients, one of whom, if possible, should have had the same trouble and got the better of it. Treatment of functional paralyses and hysterical symptoms by hypnosis and psychotherapy has given excellent results with a high percentage of permanent cures. Psychotherapy is the chief method of treatment adopted at the Neurasthenic Hospital, Maghull. It embraces suggestion, persuasion, therapeutic conversations, re-education, and exercise of the functionally paralysed limbs. The physician, as it were, masters the patient, gains his entire confidence, analyses his troubles and morbid ideas, and sets his mind at rest.

A Special Neurasthenic Invaliding Board under the Ministry of Pensions deals with shell-shock cases, and most difficult are these patients to adjudicate upon, for many will recover completely when they are once out of the army, and have lost all fear of ever again being in the fighting line. It is doubtful whether any of the many I have examined in this command will be fit for active service in the fighting line during this campaign, but I believe nearly all will ultimately recover, and many of them are brave fellows (there are V.C.s among them) who have given of their best in the service of their country.

WAR PSYCHOSES OCCURRING IN CASES WITH A DEFINITE HISTORY OF SHELL SHOCK.

BY

MAJOR R. EAGER, R.A.M.C.,

MEDICAL OFFICER IN CHARGE, MENTAL DIVISION, THE LORD DERBY
WAR HOSPITAL; SENIOR ASSISTANT MEDICAL OFFICER,
THE DEVON COUNTY ASYLUM.

THE opinions here expressed have been formed from the examination of over 4,000 cases of soldiers admitted to the Mental Division of the Lord Derby War Hospital from the Expeditionary Forces. The symptoms have been all quoted from personal records and observations on cases where the history showed definite proof of actual close proximity to shell explosion.

The following were by far the commonest: Amnesia, melancholia, mental confusion, delusions, and hallucinatory disturbances. The condition of stupor was also met with, but was not so common as the aforementioned, and in some instances the sequence of events showed that cases which had been admitted to hospital originally as definite cases of "shell shock" have subsequently passed into a neurasthenic condition, which again has not improved, but drifted into states closely resembling dementia praecox. Retardation of thought was a pronounced symptom in the majority of cases; mutism and deafness were also met with. Associated with the above symptoms were headache, insomnia, terrifying dreams, general nervousness, and varying strange sensations in the head. As regards the physical signs, the deep reflexes were always very much increased, tremors were present almost universally in the tongue and outstretched hands, and the pupils were generally dilated. Frequently patients complained of throbbing sensations in the precordia, clamminess of the skin, and appeared before one as highly strung and emotional.

Amnesia.

This, in my experience, is by far the most common symptom; the cases that have come under my review have covered periods of very varying duration. I will give a few of the very many instances:

CASE I.

Pte. L., admitted with the history that after leaving the trenches he had absented himself from his unit, and when found could not state where he had been or what he had done with his belt or bayonet. He appeared generally strange, and on this account was evacuated to England as a mental case. The period of absence in this case seems to have been only a few hours, but on recovery from his accompanying mental symptoms in this hospital he sternly denied that he had any recollection of what happened or where he had been during

* This rule requires qualification. It means electricity and massage in unskilled hands, and not in those of the skilled physician, to whom electricity is most useful in demonstrating to the patient that his muscles will act if he has confidence and will make the effort.

this time, and excused himself on the grounds that he had been recently subjected to a very heavy bombardment and felt "done up" when he left the trenches owing to loss of sleep.

CASE II.

Gnr. P. was serving the gun when he was knocked over by the recoil. Shells were bursting around him and he was carried to the dressing station. He remembers nothing till he found himself on a hospital ship coming to England. Documents accompanying the case showed that upon August 18th, 1916, he was found wandering away from his unit, and as he did not reach England until August 21st, it is certain that his period of amnesia must have lasted over two days at any rate, and perhaps longer. He could recall nothing from the time he went to the dressing station till he was on the boat.

CASE III.

Pte. H. was admitted to a casualty clearing station on September 17th, 1916, with a report that he had been buried by a shell. He could give no information about himself in the various hospitals he had passed through, and was eventually admitted to the Lord Derby War Hospital on October 4th as unimproved. Upon recovery, which was gradual and indefinite, he stated that he recollected something happening in the shape of a shock to his head when in the trenches, but nothing more. He did not remember going into hospital, and until October 12th did not seem to be able to remember anything.

Many other instances could be quoted, but it is thought that the above typical instances will suffice.

Melancholia.

All grades of this condition were met with and were often associated with active suicidal promptings. I quote the following as examples:

CASE IV.

Pte. D. was admitted to hospital in France in July, 1916, as a case of shell shock, for which he was sent down to the base; after being a week there he was returned up the line again as an officer's servant. After having been again under bombardment in the trenches he became strange in his manner, and the officer to whom he was servant noticed that he was very depressed. He was again admitted to hospital on this account on August 19th of the same year, and eventually transferred to the Lord Derby War Hospital, where his most prominent symptoms on admission were those of melancholia and complaints of great pains in the head.

CASE V.

Gnr. C. had been three months under considerable trench and shell experience when he noticed that he was unable to sleep at night and felt "queer." He carried on for another four weeks, when he mentioned it to his corporal, but asked him to say nothing to the doctor. Two months later he was reported sick owing to the fact that he was quite unable to do his duty and had refused anything to eat or drink for several days, and would not answer questions. He was admitted to hospital, where he was found to have several sticks of cordite in his pocket. He was evacuated down the line, where he is described as being in a depressed mental condition, seldom saying anything more than "Yes" or "No," and eventually admitted to the Lord Derby War Hospital in much the same condition, presenting all the features of melancholia.

CASE VI.

Pte. F., on July 1st, 1916, when in a dug-out, was hit on the head by shrapnel splinters. He was admitted to hospital, apparently with superficial wounds, and remained there ten days. He was then discharged to convalescent camp; whilst there, he felt his head bad, and was eventually found walking about with an open razor in his hand in a dull, depressed condition. He was evacuated to England, and admitted in the middle of September to the Lord Derby War Hospital, showing still a good deal of depression, and answering all questions in a melancholic voice. He said he felt worried about what he had seen in the trenches, and this kept him awake at night. He was in a typical melancholic condition.

Confusional States.

The symptoms under this heading varied from general muddled feelings in the head to a complete disorientation of time and place, and attacks of complete amnesia.

CASE VII.

Pte. R. was knocked out by shell explosion at Albert on July 12th, 1916, and appears to have been buried also. He was evacuated to the base, and was admitted to the Lord Derby War Hospital early in August, when he presented a dull, heavy, far-away look, with general confusion of thought, and difficulty in concentrating his attention. He stopped in the middle of replies to questions, as if muddled and unable to express what he wanted to say. He complained of a dizziness in the head, as well as severe occipital and vertex headache, and also of buzzing in the ears. He often repeated the last word in reply to questions—for example, asked when he went to France for the second time, he said, "May, 1916, 16, 16, 16." His mentation generally was slow, and there was considerable difficulty in obtaining

from him any history of his experiences. He said, in fact, that he "could not think," but that he had been all right until the shell came.

CASE VIII.

Pte. M. was buried by shell about the middle of August, 1916; he tried to carry on, but was noticed acting strangely. He was brought before his R.M.O. on this account on September 5th and evacuated to the base. He was eventually admitted to the Lord Derby War Hospital in the middle of September in a very confused condition, completely disorientated in time and place, and apparently thinking that he was still in France. Otherwise, in answering most questions he was sensible, and could give a good account of his experiences prior to being buried. His memory for recent events, however, was very defective.

CASE IX.

Spr. J. He describes two shells dropping about the end of June, 1916, one on each side of him, in a front line trench. He said he had the sensation as if his head were off, and he felt very much shocked but did not lose consciousness. He returned to his billet, and the next morning complained of pains in his head and a shivering feeling all over him. On this account he was evacuated to the base. He was admitted to the Lord Derby War Hospital on August 25th complaining of severe pain in his head, especially at night, which prevented him from sleeping, that he had a muddled feeling in his head, and could not concentrate his mind on anything. There was some degree of melancholia also, but the prevailing symptoms were those of confusion and inability to give any details of his illness, associated with extreme nervousness, amounting even to fear when spoken to.

Delusional States.

All forms of delusion were met with, some taking even the grandiose type, which, associated with the tremors and markedly increased deep reflexes, led to the erroneous diagnosis of general paralysis in a few instances. The commonest delusions met with, however, were of the persecutory type. The three following examples will suffice:

CASE X.

Pte. D., at the end of April, 1916, after having been ten months on and off in the trenches and subjected to heavy bombardments, complained of pains in his head and noises in his ears. During the night he began roaming about, and was sent sick to a field ambulance. He was described as being, when there, in a dazed condition; he was thought to be suffering from severe nervous exhaustion, and was passed down the line. He was eventually evacuated to England and admitted to the Lord Derby War Hospital, where it was elicited that, in addition to other symptoms, he had the idea that the hospital was mined, was apprehensive that some commotion was going on outside the building, and stated that he often heard the sound of rifles going off.

CASE XI.

Another man thought the men of his regiment were plotting against him and were trying to get him into trouble, that they sneered at him and made insulting signs at him, that they talked outside his billet and called him filthy names.

CASE XII.

A third man seemed to think that he had done something wrong and that other people thought that he had committed some crime for which he was going to be shot.

Instances in which the patient had the idea that he was being looked upon as a German spy were so common that they deserve mentioning on this ground alone.

Hallucinatory States.

Both aural and visual hallucinations were met with, but the former were more common. The following are cited as examples in which the hallucinations were the predominant feature.

CASE XIII.

Pte. D., after service in the Dardanelles, where he contracted dysentery and was invalided back to England, rejoined his regiment and was sent to France. There he was subjected to very heavy bombardment in the trenches, and said that he absolutely could not stand it and had to put his fingers in his ears—it so frightened him. He was sent from his regiment to a field ambulance towards the end of April, 1916, complaining of pains in the head and noises in the ears, and on examination was found to be in a very lost mental condition. He was evacuated to the base and subsequently transferred to England and admitted to the Lord Derby War Hospital, where he was found to have passed through an attack of complete amnesia. He described a heavy bombardment going on and that the next thing he was aware of was finding himself in hospital. He was very depressed and acutely hallucinated, saying that he heard "the voice of God" reprimanding him for his past misdeeds. This condition remain fixed, and he subsequently developed the delusions that his bed was affected by electricity and that he was the subject of magnetism. This condition still persisted after eighteen months' residence.

CASE XIV.

Another man who was found wandering from his unit after heavy bombardment was admitted to hospital in a dull, listless, and apathetic condition. On admission to the Lord Derby War Hospital he stated that he had distinctly seen a vision of his mother whilst he had been in bed at night. There was also a period of complete amnesia in this case from the time he was found wandering till shortly before his admission to this hospital, covering a period of about twelve days.

Many of the symptoms above quoted were, of course, associated in the same case, and the following *précis* of the history and progress of such cases will now help further as illustrations:

CASE XV.

Pte. H., aged 23, gave no history of any nervous or mental trouble in his family. He left school, aged 13, Standard VI, and assisted his father, a furniture dealer, in which work he was occupied at the outbreak of war. He had had no illnesses of any importance up to the time of his enlistment in November, 1915. He went to France in April, 1916, and was in the Somme advance. He was admitted to hospital in France as a case of "shell shock" in August, 1916. He complained of very severe headache, and was unable to give his number, name, or regiment. The day after his admission he was found wandering along the road about half a mile away from hospital in a confused condition. He was returned to the hospital and kept for a further period under observation, during which time some suspicion was aroused as to his being a malingerer. It was finally decided, however, that he was "weak-minded," and he was evacuated to England as a case of "dementia."

When admitted to the Lord Derby War Hospital in the first week of September, 1916, he complained of "feeling funny in his head," and that he could not sleep at night owing to the thoughts of his experiences in France. He was unable to give a clear account of how he reached hospital, but had some hazy recollection of being in a base hospital in France. The last thing he recollected clearly, however, was being with a machine-gun section in the trenches. No hallucinations could be elicited, and although he was somewhat slow in his reply to questions he showed no signs of being a mental defective. Physical examination revealed no wounds or signs of injury and no stigmata of degeneration. No marked neurological signs were present. The case progressed satisfactorily under treatment; he regained his full memory for both recent and remote events, and on November 21st, 1916, was sufficiently well to justify his being discharged from hospital to duty for home service.

CASE XVI.

Gnr. G., aged 22. No nervous or mental trouble could be traced in the family. He left school, aged 13, Standard ex-VII, and started work as a cabinet maker, which trade he worked at up to the time of his enlistment. He had had no previous illnesses and was a teetotaler. He joined the army in July, 1915, and went to France the following month. On August 9th, 1916, about 2 p.m., he asked a lance-corporal of the Military Foot Police if he could assist him in getting to England; as he appeared strange in his manner he was detained by the police and taken to hospital. Here he is described as "an idiot," and could not account for how he got there. He said that "Flo came to him yesterday and told him to go home." He was eventually evacuated to the base and transferred to England.

When admitted to the Lord Derby War Hospital, early in September, 1916, he appeared quite rational, but stated that he did not know what had happened to him, and thought he had had shell shock, but that he now felt quite fit except for occasional feelings of nervousness. He remembered going to sleep in a cellar near the firing line when some shelling was going on in the neighbourhood, but could recall nothing more till he "woke up" and found himself coming over to England. Before this he had on one or two occasions felt as if a rifle had gone off between his two ears, which had startled him very much and made him very dizzy. He had had no leave since he had been in France, and had felt considerably exhausted. Intellectually he was well up to the average standard, and his memory, apart from the above described period of amnesia, was quite good, and his power of retention unaffected. Physically he presented fine tremors of his outstretched hands, but no other marked neurological signs. He progressed satisfactorily, and on October 3rd, 1916, was considered fit to be discharged to duty for home service.

CASE XVII.

Cpl. B., aged 23, gave no family history of any nervous or mental trouble. Was up to the average standard at school, and employed helping his father as a confectioner up to the time of his enlistment. He went to France about July, 1916; in August he was blown up by shell and evacuated to England and admitted to the medical division of the Lord Derby War Hospital as a case of "shell shock." He was discharged to duty in May, 1917. On his arrival at his unit he appears to have been considered unfit for duty and immediately sent to hospital again. While under treatment there he appears to have been subject to attacks of excitement, during which he was described as a danger to bystanders, and it was on this account that he was sent back to the Lord Derby War Hospital on September 17th, 1917, and admitted to the mental division.

He was a somewhat pale, apprehensive-looking youth, who replied to all questions in a whisper. He stated that he had been dumb for several months, and that his voice had returned

of its own accord, though never more audible than it was then. He said he could not sleep owing to noises in his head, and he appeared to be in a very highly strung, nervous condition and easily upset. He admitted having attacks in which he had lost his self-control, and said that at times he seemed to have lost consciousness. At the time of examination no evidence could be obtained of visual or auditory hallucinations. He stated that during his attacks of excitement he seemed to visualize that he was out in the trenches fighting again. Physical examination revealed tremors in the upper extremity, increased deep reflexes and somewhat dilated pupils, which, however, were active to light and accommodation. On laryngeal examination no evidence of any paralysis could be found, and the aphonia was considered to be purely functional.

After three weeks' active treatment by suggestion his voice returned to normal for the first time for twelve months, and he said he slept better and felt improved in every way. The improvement was maintained, his tremors passed off, and on August 29th, 1917, he was discharged from hospital to his home to resume his former occupation.

CASE XVIII.

Pte. J. gave no history of any nervous or mental trouble in the family. He left school at the age of 15, well up to the average standard, and had since been employed in clerical work. He had also devoted a good deal of time to gymnastics, besides being an assistant scoutmaster two years and a half prior to enlistment. He joined the army in August, 1914, and went to France in 1915. Towards the end of June, 1916, up to which time he had been subjected to considerable shell and trench experience, he was reported as strange, and wandering about aimlessly, frequently speaking of spies, and wishing to search for them. It was on this account that he was admitted to hospital, where he is described as being in a continuous state of tremor, and to walk about like an old man. He asked to be allowed to make an expedition into the woods to find spies he knew to be hiding there. He was evacuated to the base, and transferred to England. When admitted to the Lord Derby Hospital about the middle of July, 1916, he was conscious, and aware of his position and surroundings, but stated that he could not recall leaving the trenches; that during the whole of his passage through the different hospitals he seems to have been in a confused condition, and not able to explain himself. He still felt that he had not the same control over himself as formerly, but said that he was feeling better and stronger. He had a difficulty in concentrating his attention, and when people were talking to him he often found that he had to ask them what they were saying; his mind was continually wandering to the sights he had seen in the trenches; on one or two occasions he had found himself crying, and did not know what he was crying for. The apex beat was heaving, and the heart sounds were very much accentuated. He complained of a throbbing sensation over the precordia. There were marked tremors in the tongue and upper extremity, and the deep reflexes were all increased; the pupils were dilated, though normal in reaction. The case progressed favourably, and on November 18th, 1916, he was well enough to be returned to duty for home service.

Many more cases could be quoted, but the above seem to be fairly characteristic examples. Before concluding I should like to emphasize the present-day importance of the differential diagnosis between all shell-shock cases and general paralysis of the insane. I have met with quite a number of cases in which the latter was diagnosed as shell shock, and vice versa, and have been particularly struck with the remarkable similarity of symptoms in many cases. In quite a number in which there was a definite history of being blown up by shell patients have presented confusional states with considerable loss of memory associated with tremors of tongue, facial muscles, tremors in the outstretched hands, increased deep reflexes, syllabic stumbling in the speech, and even delusions of grandeur. Careful examination of the pupil reactions, together with ophthalmoscopic examination of the fundi and Wassermann reaction of the blood and cerebro-spinal fluid, however, has corroborated or negated the diagnosis.

I have seen a few remarkable cases in which shell shock and general paralysis were associated in the same patient.*

Hyperthyroidism is another condition which requires to be carefully excluded in the diagnosis of "shell shock."

In reviewing the family histories of cases it was found that the number in which there was definite admission of any nervous or mental trouble in the patient's family history was comparatively small. On going through the histories of fifteen cases, one showed that the patient's maternal cousin and maternal grandmother had been inmates of an asylum; another that his paternal uncle had

* Since recording these opinions a summary of Dr. Ramsay-Hunt's observations whilst employed in the routine neurological examination of 1,500 men in an American officers' training camp has been published in the *Medical Review* of March, 1918, to which I must refer the reader.

been in an asylum; a third that his brother was a ne'er-do-well, and that his mother died of a "stroke"; and in a fourth case the patient's mother was a doubtful epileptic. In the remaining eleven cases the family was free from nervous or mental trouble. In dealing with the question, however, one has a feeling that these histories are by no means always reliable, and in dealing with men coming from all parts of the world it is impossible to corroborate them.

In conclusion, I should like to state my agreement with other writers on the subject that the predisposing causes of these conditions has no doubt been "fear." The fear of being afraid is now commonly recognized as a very important factor in the production of all functional conditions, but want of sleep, cold, wet, and the appalling sights at the front have all no doubt contributed their share to the climax which has been brought about by the shell explosion, when each individual reacts to emotions according to his personality.

THE EARLY STAGE OF HYSTERIA.

BY

CAPTAIN M. CULPIN, M.B., F.R.C.S.,
R.A.M.C. (TEMP.).

For three years I have been interested in the diagnosis of functional nervous disorders, and I have observed certain facts which seem to me of fundamental importance.

Three classes come up for consideration:

A. The *malingeringer*, who has determined to attain a definite end by the simulation of disease. This is not a large group and does not call for special attention here.

B. The man who goes sick with *feigned or exaggerated symptoms* without any more definite object in view than, say, to avoid a route march or an unpleasant fatigue. A patient of this class at the time when he reports sick may be suffering from that feeling of tiredness which at times comes to all of us, and which is called by the French soldier "*le cafard*." This word was rendered into English by an official interpreter as "the hump." "To swing the lead" is a well-known phrase, and, like all successful slang, expresses a *nuance* which no other set of words conveys. It is of nautical origin, and when used by a soldier signifies "to plumb the stream of consciousness of the medical officer." The man who "swings it" is not a pure malingerer and has not set out deliberately to carry a deception through to an end; he is only "trying it on," and if he fails he returns to duty with but a small grievance against his medical officer.

C. The *hysteric*, who differs from the members of Groups A and B in that he has a belief in the reality of his disability. In addition to this belief there may be other manifestations showing that the disability is associated with a change in the personality of the patient.

Between these three groups, members of which when typical are easily distinguished, intermediate and doubtful cases occur, and although in theory Groups B and C should be quite distinct, yet I have seen many cases in which I could not make the distinction.

Of cases falling within Group B numberless examples are admitted to hospital with the most varied diagnoses—"cerebro-spinal fever," "appendicitis," "peritonitis," "laryngitis," "tabes," "internal derangement of the knee," "pleurisy," "myalgia," "rheumatism," "gastritis," "D.A.H.," etc., have all within my knowledge been credited to patients who were suffering only from "*le cafard*," and the men have gone back to duty after a single interview, satisfied to be given the chance of escape from a false position without undue loss of self-respect.

The importance of Group C is realized by few. With the single exception described below, I have never watched the development of hysteria *ab initio*, nor apart from so-called "shell shock" can I find such a case described in the literature; nor have I met a medical man who has watched a case from the beginning. Neurologists, as such, never see one until it is fully developed. So far every case of hysteria I have seen in the army, again excluding examples of "shell shock," had been diagnosed and treated as organic disease. This, with the fact that I have seen from its origin only a single example of hysteria, though I have been watching for cases for three years, explains why

we never find them described. The officer who is able to diagnose and describe such a case never allows it to progress.

In my wards a man recovering from a wound has always been encouraged to use his limbs as soon as possible, but many patients are seen in whom a hysterical paralysis or contracture has followed a more or less trivial injury.

The history of my one case is as follows: A soldier sustained a fall and was admitted to hospital with a bruise over the ilium. He complained of severe pains, increased by pressing apart the iliac spines. I suspected a fracture of the pelvis, put on a tight binder, and had the bones radiographed. Then he began to complain of pains down one leg, where I found alterations in sensibility and a loss of power which puzzled me considerably, I being for the time off my guard. Ten days later the foot on the affected side began to assume a varus position, which I recognized as hysterical. Energetic treatment removed all the manifestations. He returned to duty, and was seen by me some months later, when he was quite fit. Looking back upon this case, I have no doubt that if I had applied those tests for superficial hyperaesthesia which I have described in a previous article,¹ I should have found that the original pains were largely of mental (psychical) origin, and I should have missed a valuable but unintentional experiment.

I have returned to duty scores of men diagnosed as "myalgia," "sycovitis," "arthritis," and what not, whose symptoms I have proved to my own satisfaction to be not of organic origin. What can be the result if such patients are solemnly treated as if they were suffering from real disease? The answer is given in the introduction by Colonel Aldren Turner, C.B., to the translation of *Les Psychoneuroses de Guerre*, by Roussy and Lhermitte, where he writes, "It is not exceptional to find paralyses and contractures preceded by more or less vague pains in the joints of limbs which have been bruised."

The conclusion is forced upon me that Group C is largely derived from Group B; in other words, the "lead-swingers" diagnosed as suffering from organic disease becomes, frequently at any rate, a hysteric.

This conception, which makes the phenomenon of disability precede the hysteria, is a reversal of that usually held; but it is based upon observations which have been inaccessible to pure neurologists. The only investigations I have been able to discover upon early cases were those carried out by Babiński and his co-workers, and they resulted in the overthrow of the classical description of hysteria, and the relegation of stigmata into the background.² If we go still nearer the fountain-head, and work for a while in the duty room of a home hospital to which the local sick are brought, a series of cases will be found there in which all manner of paraesthesias can be elicited and demonstrated.

It is often possible before examining a patient of this class to prophesy what the findings will be. Thus, in a patient who knows his complaint is diagnosed "arthritis of the knee" one can practically always demonstrate "pain" to pressure upon the adductor tubercle when this is approached by the examining hand from above downwards; a light touch with the point of a pin will be said to be painful over an area corresponding to the adductor tubercle, and similar reactions may perhaps be obtained over the head of the fibula. The reason for this is, as I believe, that the patient does not know what are the symptoms of the disease, and therefore watches for what the examining doctor is seeking, and takes care that the doctor is not disappointed.

When I first saw the patient whose case is related above I searched for evidence of pain on separating the iliac crests, and naturally therefore I found it; but when at a later date I examined the leg my mind was open as to what I might find, with the result that I only succeeded in puzzling myself. Had I examined for a stocking anaesthesia I might, and probably would, have found it.

In another case I looked only for the ordinary symptoms of a chronic appendicitis, found them, and removed the appendix. Disability persisting for a long time, I looked for extraordinary and absurd symptoms, found them, and returned the man to duty.

It is not uncommon to prick a "weak" or "paralysed" upper extremity and see the patient flinch. Then, if one asks the question, "Did you feel that?" he answers "No,"

and for the rest of the examination never flinches again. This phenomenon I have noted in three cases where there was extrinsic evidence of malingering.

Babinski demonstrates the rarity of "hysterical anaesthesia" by blindfolding the patient and telling him to point to the spot touched. This method avoids hinting at anaesthesia, but conveys a different suggestion, and I have found that the patient sometimes fails to localize the spot correctly. For either of these methods to yield instructive results a "virgin subject" is necessary.

That the blessed word "suggestion" is not a sufficient explanation for these phenomena I satisfied myself recently during a month spent in the receiving room of a London civil hospital. I examined many cases in search of suggestibility, and found it but twice—once in a nervous girl suffering from acute appendicitis, and once in a man upon whose foot a barrel had fallen whilst he was at work.

The objection will certainly be raised that those patients who become definite examples of Group C, and therefore fall amongst the hysterics, were hysterics from the start; and seeing that the differential diagnosis is, apart from extrinsic evidence, only a matter of judgement upon the part of the examining medical officer, and cannot rest upon signs or symptoms, the objection is hard to answer. I can only say, "Go and look"; make your own observations, and see if they do not lead to the opinions to which I myself have been forced.

The number of cases sent to hospital depends largely upon the medical officer. One medical officer may send five a month, another in similar circumstances may send in fifteen a month, or even fifty a month, all nicely diagnosed. If the extra ten, or forty-five, or whatever the number may be, are all claimed as hysterics I cannot contradict, or if they are "lead-swingers" I cannot prove that any would become hysterics if they were treated as suffering from real disease. I can only point to a steady influx of one type of case, to the presence of intermediate types which I myself can never differentiate, and to the increasing numbers of the finished product—the hysteric who gives a history of having been diagnosed and treated as a case of organic disease. The transition from one to the other can be explained according to modern conceptions of psycho-pathological processes, but for the present I refrain from theory.

MEDICAL ASPECTS OF THE FOOD PROBLEM.

ABSTRACT OF A PAPER READ BEFORE THE WEST
LONDON MEDICO-CHIRURGICAL SOCIETY
ON APRIL 5TH.

By ROBERT HUTCHISON, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

THE present shortage of food as it affects health may be considered in various aspects:

I. The Effects of a Diminution in the Diet as a Whole.

The needs of the body in terms of energy under different conditions have been determined by physiologists with great accuracy. Thus a patient at rest in bed requires an intake of about 1,800 calories, an ordinary man engaged in sedentary or intellectual work about 2,450, and a man doing an average day's muscular work about 3,450. For really laborious work about 4,000 calories or more are required. The contention that brain workers do not require much food is not a mere scientific theory as some writers in newspapers would have us believe, but is a thoroughly established scientific fact.

If the intake in energy in the form of food falls below these figures weight is lost owing to body fat being consumed to make good the deficiency. Thus a reduction in the fat ration of $\frac{1}{2}$ lb. a week would entail a loss of a stone in weight in seven months. The loss, however, is not progressive. After a time the individual "touches bottom" and is able to maintain a lower weight on the diminished diet. This result is rendered possible by the lessened output of energy required for transporting a smaller body weight and also, according to Lusk, by an economy in

"fundamental metabolism." The loss of fat, also, means a lesser body surface with diminished heat loss, though this may be to some extent set off by the removal of some of the blanket of adipose tissue.

Most people have lost weight in this way during the last few months, but if the loss be not out of proportion to the total body weight they may be reassured. A 10 per cent. loss is probably not excessive, and is often accompanied by a real improvement in health. The loss of weight may be retarded by warm clothing, by avoiding unnecessary exertion, and by liberal hours of sleep. There is, of course, a danger point below which the body weight must not be allowed to fall, but it is impossible to state exactly where it is. Probably it is represented by the point at which the body begins to lose nitrogenous tissue as well as fat. Beyond this point energy suffers, and there is apparently a greater liability to disease, especially to tuberculosis. The tendency to functional nervous disorders seems also to become greater. It must be remembered that, as Greenwood has recently pointed out, many conditions of disease which have been attributed to underfeeding are really not due to too little food as a whole, but to a shortage of the specific constituents called vitamins. Hence the scantier the diet the more important it is that it should be varied in character.

2. Effects of an Altered Ratio of the Chief Nutritive Constituents (Protein, Fats, Carbohydrates).

The present restrictions tend to make the diet poorer in protein and fat and richer in carbohydrate than is usual in this country. The normal protein content of a freely chosen diet is about 100 grams or more, but there is no doubt that physiological needs can be met by much less. It is not likely, therefore, that health will suffer from a restriction of this constituent, but whilst growth is going on, during childhood and adolescence, and during pregnancy, care should be taken to maintain the protein intake at a high level. Extra rations of milk are allowed to children and pregnant women, and the needs of adolescents can be met by a free use of unrationed nitrogenous foods, such as fish, eggs, and the pulses, etc.

It should be remembered in this connexion that the proteins of meat are of specially high biological value, and it requires a relatively larger amount of most vegetable proteins to replace them. Fortunately, however, the biological value of the nitrogenous matter in the potato is peculiarly high. Meat has also a special power of increasing heat production, and its diminution in the diet is therefore less felt in summer than in winter. It will be interesting to see whether the present compulsory semi-vegetarianism has any effect in lessening the incidence of such conditions as gout, epilepsy, and migraine. It should also be beneficial to sufferers from chronic vascular and renal troubles.

On the other hand, there is reason to believe that diminished intake of protein, and especially of animal protein, increases liability to tuberculosis. The comparative immunity of the carnivora to tuberculosis is of interest in this connexion.

The proportion of the total energy which is taken in as fat or carbohydrate respectively varies greatly in different individuals, 100 grams of fat to 400 of carbohydrate being perhaps a fairly common ratio. From the point of view of heat and energy production in the body it is a matter of indifference which is consumed, one part of fat being equivalent to two and a quarter of carbohydrate. It is an interesting question whether there is any part played by fat in metabolism which cannot be taken by carbohydrate. Rickets, for example, has been attributed to deficiency in fat, although on rather uncertain evidence, and it is generally believed that fat has a specific power of preventing tuberculosis. On the other hand, a diet relatively rich in carbohydrates may bring out a latent tendency to diabetes, although this is not likely to happen so long as sugar is as scarce as it is at present.

It is, however, on the digestive organs that the effects of a disturbance in the normal ratio between fat and carbohydrates is most likely to be felt. A relative excess of starch tends to favour gastric hyperacidity. The present diet also is undoubtedly bulky and flatulent, mainly because it is rich in cellulose. It is chiefly in the intestine that flatulence results, owing to the production of marsh gas, but the bulk of the diet may be trying to an atonic

stomach. This may be obviated by careful chewing and by not drinking at meals. Flatulence in the colon is usually not troublesome unless associated with constipation. Care should therefore be taken to regulate the bowels with a mild laxative, if necessary, although some patients find the present diet itself rather laxative, and if the colon be irritable it may even lead to diarrhoea, which a little bismuth or chalk will correct. In all these cases green vegetables should be avoided as they are rich in cellulose and do not add much to the nutritive value of the diet.

Carbohydrates have, of course, to be avoided by diabetics for metabolic reasons and by children with so-called coeliac disease, possibly because of defective pancreatic secretion, but for both these classes of patients special provision has been made in the rations.

3. Effects of Alterations in Quality of Staple Foods.

The chief staple food the quality of which has altered since the war is bread. The present bread contains more of the husk of the wheat grain than the pre-war bread, besides added cereals such as maize, barley, rice and oats. Chemically it is superior to white bread, and experiments have shown that it is as well digested (in the physiological sense). Patients, however, often complain that it is "indigestible" (in the popular sense). Most of these complaints are imaginary, and should be disregarded. Those with whom it is most likely to disagree are old persons with defective teeth and feeble stomachs, especially if the heart's action is also defective. Patients with any form of colitis, too, may find the bread irritating. Thorough toasting and careful chewing will get over the difficulty in most cases without having recourse to the undesirable practice of sending in a demand for white flour.

The only other staple foods which have altered in quality are meat and butter. Meat is less fat than it was, but this is not a matter of much moment, as much of the fat of meat used to be wasted. Butter, of course, has largely been replaced by margarine. The food value and digestibility of this substitute are practically the same as that of the genuine article, but there is reason to believe that margarine is deficient in certain vitamins which are present in butter. Where the diet is varied, however, this is not likely to affect health, although it might be detrimental to children fed almost entirely on bread and margarine.

Although milk has not deteriorated chemically in consequence of the war it is worth considering whether it is not more impure bacteriologically than formerly. There is some reason to believe that there has been a substantial increase in tuberculosis—especially of the abdominal form—amongst children in recent months, which may perhaps be attributable to milk. This is a matter deserving further attention and inquiry.

CONCLUSION.

Reviewing the whole question, it may be said with confidence that there is no reason to suppose that the food difficulties of this country, so far as they have gone at present, have had any adverse effect on health; if anything, their tendency has been perhaps in the opposite direction.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

COLLOID COPPER AND CANCER.

On August 3rd, 1914, a lady suffering from scirrhus of the right breast was sent to me by Dr. Hinds of Chillingham, near Canterbury. A complete operation was performed, and the patient returned home. On February 17th, 1916, she came to consult me again with a recurrent growth at the lower end of the scar over the cartilages of the ribs. This was excised down to the perichondrium. In March, 1917, Dr. Hinds sent her to see me again, as she was losing flesh, and there was a nodule in the liver. Of this there could be no doubt. There was a distinct nodule, slightly tender when pressed upon, on the lower edge of the right lobe of the liver, outside the region of the gall bladder,

obvious to the patient herself, who indeed had been the first to discover it.

Injections of colloid copper were commenced at once. I saw the patient again on June 15th after thirty-four injections had been given, and made a note to the effect that the nodule was decidedly smaller. In March, 1918, I saw her again. There was no trace of the nodule to be felt. The liver was not enlarged in any direction, and the patient had put on half a stone in weight. The injections, which had been continued once a week, were left off.

I am fully aware of the many sources of fallacy in such a case as this. *Post hoc* is not *propter hoc*. There is no proof that the nodule was cancerous. Even if it were, secondary deposits of cancer in a far more advanced stage have been known to disappear without any treatment at all. But the fact remains that this nodule, about the nature of which three medical men who saw it, besides myself, had no reasonable doubt, disappeared under injections of colloid copper, and that the diminution in size began immediately after the injections were begun. The unmistakable improvement in the health of the patient, which was coincident with the disappearance of the nodule, must be associated with it, but in what way, whether as consequence or cause, will depend upon the view that is taken as to the effects of the copper.

It is to be noted that liver cells appear to have a special affinity for copper salts. It does not follow, therefore, that if the colloid copper were the cause of the disappearance of the growth in this case it would of necessity have an equal degree of influence upon cancerous growths in other organs.

C. MANSELL MOULLIN, M.D., F.R.C.S.,

Colonel R.A.M.C.(T.), Consulting Surgeon to the London Hospital.

SHELL WOUND OF THE PANCREAS CAUSING PANCREATIC PSEUDO-CYST.

I was much interested in the case reported by Mr. John Morley in the JOURNAL of March 23rd, p. 341, as I saw an example of this rare condition in France last year.

The patient was a French soldier who had been wounded ten months previously (August 1st, 1916) by an aerial torpedo. In addition to various other wounds he had one in the left loin, but repeated x-ray examinations showed no sign of retained shell fragments. When first seen by me the abdomen was greatly distended and respiration and digestion much embarrassed. The swelling was most marked in the upper part of the abdomen, forming a rounded prominence in the epigastric, umbilical and left hypochondriac regions; the dullness over the tumour was continuous with that of the liver; the stomach, recognized by succussion, was displaced into the left iliac and hypogastric regions. On June 5th, 1917, a median supra-umbilical incision was made and a large tense cyst found, covered above by the linned-out margin of the liver. One litre of yellow, slightly turbid fluid was aspirated; the cyst was then partly drawn out of the abdomen and freely opened, when two more litres of thicker fluid, more like thin pus, were evacuated. The cyst was so large that the boundaries could not be definitely determined by the exploring finger. The cyst was marsupialized and drained for about three weeks; as there was then no further discharge the wound was allowed to heal up, and the patient, whose general condition had enormously improved, was sent to a convalescent hospital.

Dublin.

Médecin Major 2^{me} Classe.

THE VALUE OF THE WASSERMANN TEST.

RECENTLY I attended a pregnant woman who came to me with a chancre of seven weeks' duration; in spite of its typical and obvious appearance it was said not to be syphilitic because the Wassermann test was negative. In December, 1917, a patient attended for an obvious tertiary lesion; he had been discharged from hospital some few years ago as cured, because his blood was negative. In 1917 a lady went to a well-known surgeon for diagnosis: syphilis was suspected, and blood was sent to two different institutions; the report from one was negative, from the other positive; she had syphilis. Blood was drawn off, and sent to a well-known hospital, in two tubes and under two names; the report on one was negative, on the

other positive; the tests were made by the same man and on the same day; the patient had syphilis. A man attended in December, 1917, for a sore and gonorrhoea; spirochaetes were not found and his blood was negative, but he was deemed suspicious; he was only given mercury. In March I gave him novarsenobillon 0.6 gram at once, and the result was striking; the sore is now practically healed.

The Wassermann test carried out in the usual way—not with cerebro-spinal fluid—is useless; if negative it gives patients a false sense of security. Whether the result be negative or positive it means nothing as to a patient's future; whatever the result, the treatment must be carried out thoroughly.

All patients should know that one course of salvarsan does not cure; they must have more, and not large doses of mercury. My opinion is that marriage should not take place until three years at least have elapsed, irrespective of the test.

JAMES S. ROBERTSON,
Late House-Surgeon, the London Lock Hospital.

Reports of Societies.

TREATMENT OF MALARIAL RELAPSE.

COLONEL SIR RONALD ROSS, Consultant in Malaria, War Office, contributed to meetings of the Society of Tropical Medicine on February 15th and March 15th the results of an investigation started under his direction on February 15th, 1917, with regard to the treatment of malaria. It was founded upon the work done at the four hospitals for which he was from the first Consultant in Malaria—namely, in Aldershot, London, Oxford, and Epsom. A number of officers were concerned with the treatment and pathological work, including Lieut.-Colonels A. D. Milne, C.M.G., E.A.M.S., S. P. James, I.M.S., R. McCarrison, I.M.S., and Major J. B. Stephens, R.A.M.C. The number of cases dealt with was 2,460; the large majority were infected during 1916 on the Salonica front, and were examples of benign tertian. Nearly all were relapses, but a few were original infections. The word "relapse" was taken to mean the relapse of fever clinically like malaria, whether asexual parasites were found or not. Rare cases, in which a sudden increase of asexual parasites without fever occurred, were noted as relapses. Relapses occurring in malaria wards during or after a given course of treatment were always verified by the special malaria officers. Cases, however, could not be detained indefinitely, and it was therefore necessary to issue notification cards with all cases discharged from the malaria wards, with instructions to report relapses to the special malaria officers. These instructions were largely obeyed, but it was impossible to guarantee that every relapse had been reported. Further, the number of relapses given is not final, partly because some of the cases are likely to relapse in the future, and partly because further examination of records may disclose the occurrence of relapses hitherto overlooked. For these two reasons the number of relapses recorded was probably below the true figure.

Frequency of Relapses without Treatment.

Before studying the effects of different treatments it was thought advisable to obtain statistics as to the frequency of relapses occurring among men who had been taking quinine but in whom the drug was stopped. Accordingly, 193 men admitted to the Oxford hospital either for attacks in progress or for recent attacks were watched carefully, but given no quinine; 88 relapsed within twenty-seven days after quinine treatment was stopped, 76 were not sufficiently well to allow quinine to be withheld any longer, and only 29 were considered well enough to be discharged from hospital without treatment. Thus during the month this part of the inquiry lasted only 15 per cent. of the men who remained untreated by quinine escaped either relapses or illness, so that 85 per cent. of such untreated cases remained ill, and 45.6 per cent. actually suffered from relapses during the period.

Treatment of Relapsing Cases.

The trials with various forms of quinine treatment continued from March 23rd to October 17th, 1917. The various

treatments tried were of four classes: (a) Anti-relapse quinine prophylaxis given, to 1,040 old cases of malaria; comparatively small doses, amounting to about 60 grains a week, distributed in various ways, reduced relapses to about 10 per cent. of the cases a month, and also diminished the severity of the relapses that occurred; 5 grains daily were less effective than 10, but 15 grains daily were no more effective than 10 grains daily, and were less well borne; (b) short sterilizing treatments; (c) long sterilizing treatments; and (d) mixed treatments, given to 1,420 cases.

The trials showed the difficulty of sterilizing cases entirely, and that success tended to vary directly with the magnitude of the daily dosage. The best treatment for old cases of malaria was thought to be a system carried out by Captain Meredith Harrison, R.A.M.C., at the Connaught Hospital, Aldershot. It was used by him between July 10th and October 6th, 1917, for forty-nine chronic cases of malaria, mostly of benign tertian, and mostly arrived from Salonica. Of these, only five had relapsed after the cessation of the treatment in October until the end of February, 1918. Three-fourths of these cases were examined after their original treatment at the Connaught Hospital once a week as regards clinical condition, blood, and weight; as most cases of malaria in the Aldershot Command were closely in touch with the Connaught Hospital, it is thought that the number of cases given as relapsing is accurate. The percentage of cases relapsing was therefore only 10.2. The time which elapsed between the end of the treatment and the beginning of the relapse (in the five cases which did relapse) varied from sixteen to seventy-two days and averaged 34.5 days. Captain Harrison reports that with this treatment the fever was reduced within from twelve to twenty-four hours, and that no asexual parasites could be found after forty-eight hours. The effect of the treatment as regards general improvement of health was good. The treatment was well borne by the patients, except for deafness and tinnitus, and there was very little vomiting. But the patients always object to stopping in bed for twelve days; and we are informed that this line of treatment is not yet to be definitely recommended until its effect on the sight and hearing has been more exactly measured.

The treatment was as follows: The patient was put to bed for twelve days and given daily throughout this period 15 grains of quinine bihydrochloride intramuscularly in each deltoid muscle, together with 10 grains of quinine hydrochloride in anticachexia mixture No. 1 thrice daily, totalling 60 grains of quinine daily for the twelve days. After this the patient was allowed up, and given for three days anticachexia mixture No. 2, four times a day (60 grains of quinine daily by the mouth). After this the patient was given anticachexia mixture No. 3, four times daily for fourteen days (20 grains of quinine daily). He was allowed to do light work all this time. The prescriptions were as follows:

Anticachexia Mixture No. 1.

Quinin. hydrochlorid.	gr. x
Tinct. ferr. perchlorid.	℥ v
Liq. strych. (B.P.)	℥ v
Liq. arsenio. hydrochlor.	℥ v
Acid. nitrohydrochlor. dil.	℥ v
Magnes. sulphat.	5 ss
Syrup. tolu.	5 ss
Glycerin.	℥ x
Aque	ad 5 j

For a dose, to be given as directed after food.

Anticachexia Mixture No. 2.

As No. 1, but add

Quinin. hydrochlorid.	gr. v
Acid. nitrohydrochloric. dil.	℥ v

to the dose.

Anticachexia Mixture No. 3.

As No. 1, but reduce

Quinin. hydrochlorid.	gr. v
Acid. nitrohydrochloric. dil.	℥ v

in each dose.

The mixed treatment included the use of tartar emetic, acid arsenoids, sodium quinine sulphate, ethyl quinine hydrochloride, and collosol quinine, but the results were not satisfactory.

Experiences in Macedonia.

Sir Ronald Ross also gave particulars of the results of inquiries addressed by the D.M.S. Salonica to a number of

medical officers serving there. (1) Out of 111 officers who expressed definite opinions 71 considered that 10 grains of quinine given twice a week as a prophylactic measure were of no value or were objectionable. (2) In reply to a question as to the optimum dosage for relapses in regimental aid posts, where patients may be retained for treatment for a period not exceeding three days, 63 per cent. of the medical officers were in favour of 30 grains daily. (3) In reply to a question as to the optimum dosage for recurrent cases doing duty after being kept in regimental aid posts for a few days, the majority of the 107 officers who replied recommended fixed doses of quinine for periods varying up to three and a half months. The dose recommended varied from 10 to 30 grains daily, but some of the officers recommended the gradual reduction of the dose as the course progressed. (4) In reply to a question as to the optimum dosage for recurrent cases of malaria returned from hospital, 65 out of 105 officers advised the continuance of the same daily dose of quinine, and of these 33 advised 10 grains daily for from one month to three and a half months, twelve 20 grains daily for similar periods, and sixteen 30 grains daily. Others advised the gradual reduction of the quinine as the course progressed. Subsidiary treatment was recommended by many officers.

Elimination of Quinine.

Acting Staff Sergeant M. Nierenstein made a large number of chemical examinations, and in an interim report states: "It seems more or less apparent that there is a tendency for the excretion of the quinine passed to reach a concentration of 7 to 11 grains per litre of urine. This appears to be the case for all salts experimented with (except the lactate), and the fact does not appear to be altered by the different methods of administration. Thus, these results flatly contradict all statements to the effect that quinine given intramuscularly or intravenously is more or less readily excreted than quinine given orally. Moreover, no one quinine salt appears to be more readily eliminated in the form of its base than another salt. These results have been obtained from 1,366 analyses made on 624 different specimens; and have since been confirmed in quite a number of estimations accumulated during January and February, 1918."

Reviews.

EXOPTHALMIC GOITRE.

PROFESSOR G. ROUSSY's well illustrated monograph on the changes in the thyroid gland in Graves's disease,¹ destined to be read at the Twenty-fourth Congress of the Alienists and Neurologists of France and French-speaking countries, planned to be held at Luxemburg on August 3rd to 7th, 1914, has just come into our hands, and it is perhaps curious that a discussion on a disease rendered more frequent by wars should have been arranged for a congress made impossible by the outbreak of hostilities. The subject was considered at the congress in 1895, when the thyroid changes had comparatively recently been described by Professor W. S. Greenfield and Renaut; and Brissaud, who introduced the discussion, hesitated about abandoning the nervous origin of the disease. Since then fresh data and methods have established the part played by the thyroid, and raised the question as to the significance of the persistent or enlarged thymus. As at that time exophthalmic goitre was regarded rather as a syndrome than as a disease, Roussy now separates off the rather rare cases of false exophthalmic goitre—for example, those due to the simple goitre compressing and irritating the sympathetic and those due to reflex causes—and then tabulates the following forms: the characteristic disease, the forms due to tuberculosis, to syphilis, to malignant disease, and to goitre of the thyroid gland, and the large group of the *fruste* cases, including those due to thyroidism and thyro-toxic factors. A full study of the morbid anatomy shows that there is first of all an inflammation of the thyroid, which is often overlooked, and that the presence of lymphoid collections in the gland itself and

the enlargement of the thymus and the neighbouring lymphatic glands are perhaps relics of this thyroiditis. These lymphoid areas in the thyroid, found by Roussy in 14 out of 15 cases of Graves's disease, in 2 out of 50 ordinary goitres, and in none of 60 normal thyroids, are well reproduced in the figures. The thyroid changes are those of a compensatory parenchymatous hyperplasia, and as a result the secretion is altered.

The problem of the thymus is thoroughly discussed; the first reference to its persistence and enlargement given is that by the late Sir James Goodhart in 1873, but it may be pointed out that it was noticed as early as 1858 by Markham. While admitting that the significance of the thymic change is not yet settled, Roussy believes that it probably has some influence on the symptoms and complications, if not on the establishment, of the disease.

The various methods of treatment are discussed, and a preference for x rays rather than surgical interference definitely expressed. The subject is so systematically considered that this monograph constitutes a valuable source of reference.

INJURIES OF THE FACE AND JAW.

In translating MARTINIER and LEMERLE's little book on *Injuries of the Face and Jaw*,² Captain LAWSON WHALE has done surgery an opportune service. Surgeons have had, or should have had, appreciative admiration of the great perfection to which dental surgeons have brought their mechanical skill, but it has been reserved for the conditions of war to give a complete demonstration of the extent to which prosthesis may be applied. Moreover, those dental surgeons who are also surgeons in the ordinary sense have rapidly exhibited a transference or extension of their mechanical skill to the realm of plastic repair and reconstruction, which has led to results surpassing anything in the whole literature of the past. It requires but a glance at the communications of the author himself, of Valadier, Kazanjian, and Burrows in the *British Journal of Surgery*, to give one example, to realize what is being done. It is indispensable for those who take up this work that they should be familiar with what has already been done by French surgeons to perfect preventive, restorative, and permanent prosthetic apparatus. The present work deals only to a limited extent with the plastic branch of the art, but it affords an invaluable record of what can be done for the prevention of deformity in injuries of the jaws, for the repair of distortion and defect, and for the amelioration of facial, nasal, and palatine destruction or deformity. One merit of the book for the purposes of the surgeon who must call the expert orthodontist to his aid is its brevity.

The contribution to the treatment of gunshot wounds of the jaws published by the Austrian journal of stomatology,³ under the editorship of Dr. EMIL STEINSCHNEIDER, is a well illustrated monograph by many contributors, and indicates that enemy dental surgeons are dealing with their war problems on much the same lines as our own. They have little if anything to teach us. Their apparatus is derived from original French models, but has the appearance of not being quite so delicate; consequently it must be less comfortable for the patient. The plastic work gives good cosmetic results, but there is no indication of the more difficult achievements, such as the making of new noses. The radiograms are good, well planned, and well analysed. It is surprising to see Lane's plates used in the treatment of suppurating wounds of the lower jaw with loss of substance. The book will interest those engaged in similar work.

SURGICAL APPLIED ANATOMY.

TREVE'S *Surgical Applied Anatomy*⁴ has long been a favourite, but even the most popular books must keep abreast of the times. If there was one man who could

¹ *Injuries of the Face and Jaw, and their Repair; and the Treatment of Fractured Jaws.* By P. Martinier and Dr. G. Lemerle. Translated by H. Lawson Whale, M.D., F.R.C.S. London: Baillière, Tindall, and Cox. 1917. (Cr. 8vo, pp. 345; 168 figures. 5s. net.)

² *Beiträge zur Kieferschuss therapie, herausgegeben von der Osterr. Zeitschr. f. Stomatologie.* Redigiert von Dr. Emil Steinschneider. Berlin and Vienna: Urban und Schwarzenberg. 1917.

³ *Surgical Applied Anatomy.* By Sir Frederick Treves, Bt., G.C.V.O., C.B. Revised by Arthur Keith and W. Colin Mackenzie. London: Cassell and Co., Ltd. 1913. (Fcap. 8vo, pp. 702; 153 figures, 74 in colour. 10s. 6d. net.)

⁴ *Les lésions du corps thyroïde dans le maladie de Basedow.* By Gustav Roussy, Professeur agrégé à la Faculté de Médecine de Paris. Paris: Masson et Cie. 1914. (Roy. 8vo, pp. 135; 2 coloured plates and 10 figures. Fr.3.)

work the miracle of rejuvenating a classic without sacrificing the divine spark, it was Professor ARTHUR KEITH. He has done more. In its present form this little volume teems with pleasant surprises; apt illustrations of the importance of anatomical bearings upon surgery are culled from literature and from sources unexpected, with a constant recurrence of names that produces a living atmosphere. It is not to be criticized: it is to be enjoyed, and with the enjoyment student and master will both absorb valuable information and reminder. Dr. COLIN MACKENZIE, whose name appears on the front page, is fortunate in inheriting a great tradition which, if the changes in the seventh edition be due to him, he has known how to value.

NOTES ON BOOKS.

THE fourth volume of the *British Journal of Surgery*⁵ for the year 1916-17 does credit to the editorial secretary, Mr. Hey Groves, and to the large editorial committee who direct it. Judged in volume form, from the point of view of a permanent place on book-shelves already tending to be overburdened, the opinion may be ventured that articles such as those on contemporary surgery in other lands, interesting as they certainly are, are a little out of place, at any rate at the present time. The greatest value attaches to contributions such as that of Mr. Cope, based, it is true, on a few personal cases, but giving a complete summary of recent work on the surgery of the pituitary gland, and illuminated by an excellent anatomical study; the series of papers on gunshot wounds of the abdomen; on arterio-venous aneurysms, and on diverticula of the intestine; and the papers by Bashford on the histology and general pathology of the tissues in war wounds. These and others like them are permanent contributions to surgical literature and progress. Congratulations to our contemporary.

Mr. CANDY'S *Manual of Physics for Medical Students*⁶ is a little book written especially to help candidates through the physics of the preliminary or first medical examination. It is well arranged and clearly written, and appended to each chapter are written exercises.

Dr. MALONEY'S book on *Locomotor Ataxy*⁷ has been written to show, first, how this disease is the microcosm of all nervous disorders, and secondly, how amenable it is to special forms of systematic treatment on the lines of mental therapy. The volume should be of interest to specialists in nervous disorders, as it expounds a new idea.

Professor ANDERS'S *Textbook of the Practice of Medicine*,⁸ now in its thirteenth edition, is one of the standard volumes upon which medical students and practitioners on the other side of the Atlantic rely. It is well written, full of information, up to date, and, above all, practical. Want of space forbids us to say more of its merits; it is a book that may be warmly commended.

Miss BEATRICE GOODALL-COPESTAKE has written a sound and comprehensive handbook on the *Theory and Practice of Massage*,⁹ which, while imparting a knowledge of the various procedures—as far as it is possible to do so in a book—also introduces the nurse and massage pupil to the rudimentary knowledge of those conditions in the treatment of which she may be required to help the physician or surgeon. The book is well illustrated, and includes an index and a glossary. The term "anterior poliomyelitis" is not derived from "anterior pole," as is stated on p. 196.

⁵ *The British Journal of Surgery*. Bristol: John Wright and Sons, 1917. (Vol. iv. 30s.)

⁶ *A Manual of Physics, Theoretical and Practical, for Medical Students*. By Hugh G. H. Candy, B.A., B.Sc.Lond., F.I.C. Second edition, enlarged. London: Cassell and Co., Ltd. 1918. (Fcap. 8vo, pp. viii + 451; 280 figures. 7s. 6d. net.)

⁷ *Locomotor Ataxia (Tabes Dorsalis)*. By William J. M. A. Maloney, M.D. Edin. London and New York: D. Appleton and Co. 1918. (Med. 8vo, pp. xxi + 299; 97 figures. 15s. net.)

⁸ *A Textbook of the Practice of Medicine*. By James M. Anders, M.D., Ph.D., LL.D. Thirteenth edition. Philadelphia and London: W. B. Saunders Co. 1917. (Roy. 8vo, pp. 1259; 89 figures. 25s. net.)

⁹ *The Theory and Practice of Massage*. By Beatrice M. Goodall-Copestake. London: H. K. Lewis and Co., Ltd. 1917. (Demy 8vo, pp. xvi + 251; 56 figures. 8s. 6d. net.)

A VEGETABLE MILK.

[From a Correspondent.]

IN these days of agalactia any reasonable substitute for milk is certain of a welcome, so that particular interest attaches to the soy bean, an alimentary plant grown on a very large scale in China, and imported into this country by hundreds of thousands of tons annually for the sake of the oil it contains, which is utilized in the manufacture of soap, margarine, etc. More interesting from the alimentary point of view is the fact that it can be made to yield a substitute for milk, which in respect of appearance and composition so nearly approximates the familiar article as to be wellnigh indistinguishable therefrom. The process is simple. Five ounces of the bean are soaked overnight in a quart of cold water; it is then coarsely ground, mixed with the water in which it has been soaking, and filtered through muslin. The result is a milky fluid with a rather strong smell of haricot bean, which disappears after it has been raised to boiling point. Infants take it readily, and, mixed with tea or coffee, the taste is imperceptible. Fresh soy bean milk has a faintly acid reaction; it is quite homogeneous under the microscope, and its physical properties are those of cow's milk; rennet causes it to curdle, lactic acid germs cause it to undergo lactic acid fermentation. When boiled it "rises" like ordinary milk and forms a pellicle on the surface. Its composition is: Casein 3.13 per cent., fats 9.89, but it lacks carbohydrates, a shortcoming which can easily be remedied. As the fatty constituent is an oil, butter cannot be made from soy bean milk, but it can be made to provide cheese (120 grams of the bean yields 184 grams of cheese), and the cheese can be made to resemble any of the popular cheeses in the market; it is merely a question of employing the proper flavouring ferment. Soy-bean milk can be retailed at 3 centimes a litre. The residue, after making milk, is still very rich in alimentary principles, and can be worked up into very palatable "almond" cakes or biscuits. Being practically free from starch, these cakes are specially suited for consumption by diabetics. Roasted, the bean provides a colourable imitation of coffee, just as do barley and oats, to what a satisfactory degree only those who make use of these substitutes will understand. The soy bean and its derivatives are very rich in phosphates, so that infants reared on the milk are never likely to develop rickets.

Unfortunately the soy bean does not take kindly to the English climate, but it grows freely in China, where it is indigenous, in southern France, in Algeria, and in many parts of the United States, where the plant is used extensively for fodder. There are a number of varieties possessed of special qualities according to climate and the object in view—for example, oil, or milk, or cattle food. A practical idea of its alimentary value may be formed by contrasting the cost of this as compared with other albumins: 100 grams of albumin, at before-the-war prices, would cost—from egg 1s. 8d., from meat 1s. 4d., from pork 8d., dried peas 3d., and from soy bean 2d. The bean contains four times as much mineral constituents as meat, and is twice as rich in phosphoric acid. Here is an analytical table showing the comparative values of soy beans and some of the pulses in common use as food in this country:

	Water.	Nitrog. Constituents.	Fats.	Starch.	Cellulose.	Ash.
Lentils—						
Maximum	13.50	24.64	1.45	62.45	3.75	3.45
Minimum	11.00	19.36	0.50	56.07	2.88	1.75
Haricot beans—						
Maximum	20.40	26.46	2.46	63.23	6.00	5.65
Minimum	8.50	13.80	0.40	52.04	1.95	2.20
Peas—						
Maximum	14.20	26.63	1.65	61.10	3.52	3.70
Minimum	9.80	18.88	0.85	56.18	2.38	2.00
Broad beans—						
Maximum	15.30	26.51	1.50	58.03	7.86	3.26
Minimum	10.60	20.87	0.80	50.89	5.24	2.06
Soy beans—						
Maximum	11.30	38.41	14.80	32.11	6.20	5.20
Minimum	10.00	34.85	12.95	26.74	3.60	4.35

British Medical Journal.

SATURDAY, APRIL 13TH, 1918.

THE NEW MILITARY SERVICE BILL.

THE introduction of the new Military Service Bill and the special provision which it contains with regard to medical men makes it opportune briefly to recall the steps by which the present situation, so far as it specially affects the medical profession, has been brought about. The annual general meeting of the British Medical Association in Aberdeen had ended a few days before the outbreak of war, so that the Association had no special machinery in existence for dealing with the emergency. The War Office immediately called up the medical officers of the Special Reserve, and the medical officers of the Territorial Force belonging to the combatant units were mobilized with those units. Medical officers *à la suite* of the Territorial general hospitals were mobilized as those hospitals were got ready. With the regulars and re-employed regular officers the total number of medical officers obtained from these sources was about 4,000, and nearly three-fourths of them were withdrawn completely or in part from the civil profession. At the same time an appeal was made for volunteers, one of the terms being that the volunteer undertook to serve if required for at least twelve months, with the right then to relinquish his commission. The response to this appeal produced about 1,140 by the end of 1914, and about 2,700 by the end of 1915. The first step spontaneously taken by the organized body of the profession to meet the emergency disclosed by the German advance into Belgium and Lord Kitchener's appeal to the manhood of the country was taken at the instance of the late Dr. Hamilton of Hawick by the Scottish Committee of the British Medical Association. By September the Scottish Medical Service Emergency Committee, consisting of representatives of Scottish universities and medical corporations and the British Medical Association, had been formed. In England and Wales preliminary arrangements were undertaken by committees of the British Medical Association, which reported to the annual meeting in 1915, when the Central Medical War Committee was constituted. It was instructed "to organize the medical profession in such a way as will enable the Government to use every medical practitioner fit to serve the country in such a manner as to turn his qualifications to the best possible use, and to deal with all matters affecting the medical profession arising in connexion with the war." Local Medical War Committees were set up throughout England and Wales to act with the Central Medical War Committee and to advise it as to local conditions and as to practitioners in the localities who could most easily be spared. The Committee of Reference of the Royal Colleges in England was set up early in 1916 to consider cases of doctors on the staffs of hospitals and medical schools in the metropolis, and such other special cases in England and Wales as might be referred to it. An Irish Medical War Committee was also established. Schemes were instituted by the Central Committees in England and Wales, and in Scotland, for the enrolment of all medical men up to the age of 45, the limit for general service in the R.A.M.C. The enrolled

person gave an undertaking to accept service when called upon by the Committee, and the Army Council undertook to apply to him the principle that a medical man thus offering himself should not be called upon to fulfil his obligation of commissioned service for more than twelve months consecutively.

The passing of the second Military Service Act, 1916, had the effect of imposing compulsory service on all medical men under 41. The central medical committees, thereafter called "professional committees," were recognized by an Order in Council, and were entrusted with the duty of selecting at the right time in each case the particular medical men who could be spared from their civil work with least injury to the civil population, and of retaining in their civil work those most needed there in the public interest. The Army Council undertook to refrain from applying its compulsory powers as to combatant service to a doctor of military age if, and so long as, he was enrolled and undertook to serve, and if required did serve, as a commissioned officer in the R.A.M.C. whenever this might be found necessary by the central professional committee. When called upon he was given the right of appeal to the central professional committee. If at the end of the first or any twelve months' service a medical man relinquished his commission, he, if under 41, remained liable to the Military Service Acts, but if he then enrolled he reverted to the position in which he was before he took a commission; that is to say, he went back amongst those from whom the central professional committees selected doctors for commissioned service in the R.A.M.C., subject to due consideration of the needs of the locality and his personal circumstances. The enrolment scheme continued to apply to doctors over military age, especially those from 41 to 45, and in June, 1916, shortly after the passing of the second Military Service Act, the War Office announced that it was prepared to give commissions in the R.A.M.C. to medical men between 45 and 55 willing to undertake whole-time general service in the United Kingdom. Incidentally it should be noted that newly qualified medical men automatically passed into the Reserve, and were commissioned in the R.A.M.C. (S.R.), subject only to their being pronounced physically fit on medical examination.

On the establishment of the Ministry of National Service recruiting in all its branches was transferred from the War Office to that Ministry, and medical recruiting became especially the care of its medical department, with which the professional committees have been in communication throughout.

At present temporary R.A.M.C. officers of military age on expiration of their contract are required, if they renew, to engage for the duration of the war. If an officer, however, does not wish to renew he retains his right of appeal to the professional committee, which, in deciding whether or not he should rejoin, takes into consideration the needs of the civilian population of the locality in which he practises and his personal circumstances. It is to be noted that medical officers of military age intending to relinquish their commissions after October 31st, 1917, were warned that they would probably be recalled shortly.

The first clause of the new bill fixes the military age at from 18 to 51, but there is a proviso that by an Order in Council the upper limit of age may be raised to 56 as respects men generally, or as respects any class of men, and it shall be so fixed "as respects any person being a duly qualified medical practitioner." Clause 4 gives power to make regulations by an Order in Council to establish "special tribunals, committees, or panels for dealing with particular

classes of cases," and to determine the grounds on which application may be made to the tribunals and the rights of appeal.

The Central Medical War Committee, at its meeting on April 10th, decided, after full discussion, not to press for the insertion of any amendment in the bill now before Parliament in so far as it relates to registered medical practitioners. It is felt that the older men who will now become subject to military service will in most cases serve their country best by placing themselves at the disposal of the central professional committees for medical work, in a military or civil capacity, which will release younger practitioners for active service. The method, no doubt, will vary according to local and individual conditions, but it would seem that schemes for local arrangements would produce less dislocation of practice than any general plan of long-distance substitution between the areas which are relatively understaffed and those which are more plentifully supplied with doctors. Although the total number of medical men who may be made liable to military service under the bill is large—between 6,000 and 7,000—it is unlikely that any considerable proportion would be called upon; if this is so, only a minority would be directly affected.

In the altered situation which will be brought about by the enactment of the bill, the Ministry of National Service will, doubtless, desire to remain in the closest collaboration with the Statutory Professional Committee. But it is probable that henceforward the decision on the indispensability of individual practitioners, or on questions of priority, will rest ultimately in the hands of the Ministry. The fullest use will, no doubt, be made of the advice and opinion of the professional committees, but, as in the case of all other tribunals, the last word will be said by the Ministry of National Service. In this respect the legal position will be changed, though it is not anticipated that in practice any conflict will arise between the professional committees and the Ministry.

THE TEACHING OF ANATOMY.

In Edinburgh, as in other medical centres, there is a growing feeling that our modern medical curriculum stands in need of revision, nor is it difficult to understand how this feeling has arisen. Every decade that comes along finds the medical student saddled with a new subject and a new professor, until at the present time he has to run the gauntlet of some fifteen of them. The student finds that as new professors appear the old ones extend their subjects both in scope and in detail. He finds, too, that instead of co-ordinating their collective efforts so as to make him an efficient medical man, his professors insist more and more in teaching their subjects as if their particular branch of knowledge was the sole object of study. The present discontent, then, relates not to the nature and number of subjects included within the medical curriculum, but to the fact that their professors seem apt to forget that they are members of a common team whose sole duty should be the production of efficient medical men.

During the past winter session this matter has been the subject of serious and instructive debate in Edinburgh. The members of the Pathological Club of that city invited Sir James Mackenzie to initiate the discussion; it was continued by the professor of chemistry. Now has come the turn of the anatomist—who, in the eyes of many, is regarded as the chief delinquent. It was a happy choice which led to the invitation of Professor Elliot Smith of the University

of Manchester to open the discussion on "the teaching of anatomy."¹ He has made additions of the utmost importance to the subject he professes, but has never permitted his anatomical research to obscure his medical vision. In Professor Elliot Smith's opinion "anatomy should be regarded as an integral and intimately co-ordinated part of the whole medical course, and it should be the business of the teacher to give expression to this broad view in his teaching . . . ; the teaching, in other words, should be directed towards the needs of the practice of medicine; and it should be the business of the teacher of anatomy to keep sufficiently in touch with the progress of medicine as a whole to direct his teaching towards the right aim." Therein we believe Professor Elliot Smith enunciates a very important truth; no man is qualified to teach anatomy rightly unless he follows closely the progress made in all departments of medicine. "No man," he says, at another place, "can be a really efficient and stimulating teacher unless his own mind is kept constantly alert by original investigation. Unless this is so, he is merely a purveyor of second-hand goods. The man who is actually engaged in research, and can give the student first-hand information, can also describe from his own experience the difficulties that have to be overcome, and the way progress is actually achieved." In the teaching of anatomy, as in the teaching of every other medical subject, the first essential is to find the right man. Having found such a man, the scope and manner of his teaching become secondary matters.

Professor Elliot Smith had stringent things to say about the manner in which osteology is taught. Descriptive osteology! The amount of mental effort which has been wasted over committing to memory the identification marks and multiple surfaces of the bones of the hand and foot! "I have the most vivid recollection," he says, "of the manner in which those first two terms of osteology rapidly killed all interest in the subject. It was not merely that I ceased to learn anything from the lectures, but a positive and intense repugnance to the business of acquiring a knowledge of the bones took possession of me." His opinion is that the bones are as much a part of the body as the muscles, the blood vessels, and the nerves, and should be studied as the student makes his dissections. In the dissecting room the student can see for himself the various factors which mould and shape a bone. He speaks of the osteology class as a "wicked and sterilizing farce which is still permitted to waste the student's time and kill his natural interest in the subject of anatomy."

The late Professor Franklin Mall, who did more than any one to raise anatomy to its present high position in the United States of America, abolished lectures as a means of teaching anatomy. We entirely agree with Professor Elliot Smith that in this he was in error. "I agree with Mall to this extent," he said, "that taking into consideration the limited amount of time at the disposal of the student and the excellence of his textbooks, the attempt to deliver a systematic course of lectures is wholly indefensible. . . . Instead, however, of employing the time in expounding to the student information which he can more usefully acquire in the dissecting room or in the study of his textbooks, the teacher should make it his business in the lectures to deal with aspects of anatomy which the student is unable adequately to learn in the ordinary work of the dissecting room—such, for example, as the lymphatic system, certain parts of

¹ See *Edinburgh Medical Journal*, March, 1918, where there are full reports of the papers read by Professor Elliot Smith, Professor David Waterston, Professor Arthur Robinson, and of the discussion which followed.

the nervous system—for instance, the clinically important but much neglected sympathetic system—and the anatomy of the viscera.” We entirely agree with Professor Elliot Smith that the constant use of a living model is absolutely essential for the right study of anatomy; in his own arm, leg and body, or on those of his working partner, the student can identify and study the dissected part in its living condition. X rays and skiagrams have given the anatomist, as well as the physician and surgeon, a new means of studying the anatomy of the living body. “The primary value of dissection,” says Professor Elliot Smith, “is to enable the student to find his way about the body. Much of the knowledge which he acquires is of a subconscious nature, but none the less real on that account. By a limited experience I have learnt to find my way from Princes Street to the University, but I cannot name a single street or landmark, nor give more than the vaguest description of the route; yet I have the essential knowledge which meets my needs. The vital knowledge of anatomy that it is essential for the student to acquire is of a similar nature.”

There is one grave defect in the teaching of anatomy which neither Professor Elliot Smith nor those who followed him in the discussion in Edinburgh referred to—one which exerts a particularly prejudicial influence in London. In metropolitan schools the teaching of anatomy is paralysed by the conditions which candidates have to face in the examination room. When the teacher ought to be directing his efforts to instilling the knowledge which will help his student in the recognition and treatment of disease he has to teach him to pass examinations—examinations which have become fossilized under the influence of hoary tradition. We cannot have rational teaching in anatomy, or in any other subject, until we obtain a rational method of examination. Without exception all written examinations in anatomy—at least, all questions in descriptive anatomy—lead to the accumulation and perpetuation of barren knowledge. If students were subjected to practical examinations on the living as well as on the dissected body, we should soon hear the last of the complaints often urged by physicians and surgeons—that the anatomy taught to students is useless for clinical work.

INTERALLIED SCIENTIFIC FOOD COMMISSION.

At an interallied conference, which was held last November in Paris, it was agreed that a Scientific Food Committee should be formed containing two delegates from each of the following countries:—Great Britain, France, Italy, and America. This committee was to have its permanent seat in Paris, and was to meet periodically in order to examine, from the scientific point of view, the interallied programme for food supplies. It was empowered to make any propositions to the allied Governments which it thought fit. The delegates appointed from the various countries were:—Great Britain: Professor E. H. Starling and Professor T. B. Wood; France: Professor Ch. Richet and Professor E. Gley; Italy: Professor Bottazzi and Professor Pagliani; America: Professor R. H. Chittenden and Professor Graham Lusk. The first meeting of this Commission was held in Paris on March 25th, 1918, and the following days. At their first sitting the Commission was received by M. Victor Boret, Minister of Agriculture and Food. In his opening address M. Boret pointed out that the object of the conference was to study the best means of utilizing the very small food resources at the disposal of the allies so as to effect an equitable distribution of the available food supplies among the allies, having proper regard to the facts of physiology and

political economy. He sketched shortly the work of the Commission, and his suggestions were embodied later in a series of questions which were adopted by the Commission as the problems that would immediately occupy its attention. The Commission agreed to establish a permanent central secretariat in Paris, M. Alquier being appointed secretary. In addition to the central secretariat it was agreed that a secretary to the Commission should be appointed in each of the allied countries. At its meetings, which lasted till March 29th, the Commission considered many important questions relating to the minimum food requirements of man, and to the production and distribution of food supplies. The Commission will reassemble at intervals, in Paris or in some other of the allied capitals. Professor Gley has stated that it will probably meet next at Rome towards the end of this month.

ARMY MEDICAL ADVISORY BOARD.

The Army Medical Advisory Board, established in 1901, has been in abeyance since the beginning of the present conflict. It has now been considered advisable to appoint a new Advisory Board somewhat differently constituted and with a smaller number of members. The Director-General, Lieutenant-General T. H. J. C. Goodwin, C.B., C.M.G., D.S.O., is president, and the other members are Major-General Sir Bertrand Dawson, G.C.V.O., C.B., M.D.; Major-General Sir Berkeley Moynihan, C.B., F.R.C.S.; Colonel W. H. Horrocks, C.B., A.M.S.; Colonel Sir Robert Jones, C.B., F.R.C.S.; and Lieutenant-Colonel Sir Harold J. Stiles, F.R.C.S. Sir Bertrand Dawson, who is physician to the London Hospital, is a consulting physician with the British Expeditionary Force in France. Sir Berkeley Moynihan, who is surgeon to the Leeds Infirmary, is consulting surgeon to the Northern Command. Sir Robert Jones is the Inspector of Military Orthopaedics, and Sir Harold Stiles of Edinburgh is Assistant Inspector of Military Orthopaedics for Scotland and was a member of the commission of inquiry in France. Colonel Horrocks, who was a member of the old board, again serves on the new board as sanitary expert. The secretary is Mr. A. T. Gann, who was the secretary of the old board. It will be observed that the new board does not contain, as did its predecessor, representatives of the India Office and of the directorates of military operations and of fortifications and works.

DIGESTIBILITY OF BREAD.

The report (3206), completed on March 11th, of the Food (War) Committee of the Royal Society on the digestibility of bread, has been issued this week. Some of the conclusions of most general interest were mentioned by Professor F. G. Hopkins in his lecture at University College, reported in our columns on February 2nd, p. 157. The questions the Committee set itself to answer were: (1) What gain, if any, in food value to the nation would accrue from a rise in the milling standard from 80 to 90 per cent., and whether the dilution of wheat flour with other cereals modified the food value of the bread? (2) What would be the effect on the health of the population of the consumption of such breads? and (3) How far would such breads prove acceptable to the population in general? The first set of experiments were made with undiluted wheat flour, extracted to 80 and to 90 per cent., on three groups of individuals—in Cambridge, Glasgow, and London; and the analytical work was done in the biochemical department of the University of Cambridge and in the Physiological Laboratories of the universities of Glasgow and London. The diet consisted of 800 grams of bread with butter, cheese, minced or potted meat, fruit jelly, milk and sugar, tea or coffee, and in one case beer was taken as a beverage. The dietary yielded about 3,680 calories a day. The effects

were remarkably uniform in the different individuals. During the use of bread made from the 80 per cent. flour there was extracted for the purposes of nutrition 96.1 per cent. of the energy contained in the diet; wheat bread made from 90 per cent. flour was used 94.5 per cent. was extracted. The loss of energy with the second bread was greater (5.5 per cent.) than with the first (3.86 per cent.); it is considered that the secretions of the gut contributed largely to this. The faeces with the 90 per cent. bread were more bulky, and the coarser particles of this bread produced a greater stimulation of the secretion of the gut. The increase in the bulk of the evacuation is considered not in itself an evil, and in the case of many individuals even an advantage. As to the nitrogenous constituents, it was found that the average digestibility was 89.4 per cent. in the case of bread made from flour extracted to 80 per cent., and 87.3 per cent. in that extracted to 90 per cent. In most of the cases there was a slight gain in body weight with both breads. The reply to the economic question is founded on the fact that a greater proportion of the energy of the grain is available for human consumption when flour is milled at the 90 per cent. scale than on the 80 per cent. scale. The increase was so considerable that it would extend the cereal supply of energy for the country for more than a month. Against this is to be set the loss of protein in the offal as food for pigs, but an allowance is made for this. Another set of experiments were made with bread made from flour consisting of four-fifths wheat extracted at 80 per cent., and one-fifth maize. In this series the original group of ten adults and two youths was increased by two boys and two young children, and a man considerably older than any of the original subjects. At first the flavour of the maize was commented on, and there was in some cases disturbance of digestion, attended sometimes with diarrhoea, but more often with constipation. These symptoms passed off. The general conclusion is that the bread made with the addition of maize flour was as digestible as bread made from the same wheaten flour without that mixture; it was well digested by children even when eaten in proportionately large quantities. The addition of maize made practically no difference in the utilization of energy and nitrogen. The report also contains observations made at a canteen on the dietetic effect and on the palatability of bread made from flour containing four-fifths of wheat extracted to 90 per cent., and one-fifth other permitted cereals. The cereals used were 10 per cent. barley, made up to 20 per cent. with maize and rice, or rice alone. This bread was consumed for two months by 20 men, 9 women, and 2 children. It was also taken for a month by 12 individuals—9 men, a woman, and 2 children. In no instance did it cause digestive trouble, and in certain cases the health seemed to improve. All considered the bread palatable, no one became tired of it, and the subjects of the experiment at its end drew up a memorial expressing their appreciation of the whole-meal bread, stating that they derived great benefit from its use and asking that a further supply should be obtained. A few observations were also made with bread made in the same proportions as in the factory experiments on patients in two sanatoriums for consumption—one for males and the other for females. The results were similar in the two sexes. Of 10 cases in the early stage 9 gained weight and 1 showed no change. Of 6 cases in the intermediate stage 4 gained and 1 lost weight, and in 1 the weight remained unchanged. Of 9 cases in the advanced stage, 6 gained and 3 lost weight. No evidence of digestive disturbance was noticed. All the patients preferred the special bread, with the exception of two men who said they had no preference and three who preferred ordinary bread. Dr. Robert Hutchison, in his paper on the medical aspects of the food problem, points out (p. 426) some practical conclusions to be associated with these scientific investigations.

THE PROBLEMS OF RADIOACTIVITY.

In the first Silvanus Thompson Memorial Lecture, delivered before the Röntgen Society on April 9th, Sir Ernest Rutherford, F.R.S., reviewed the various lines of scientific investigation opened up as a result of the discovery of α rays. In a tribute to the first President of the Society, in whose honour the lectureship was instituted, he mentioned that on the morning that the late Silvanus Thompson read of Röntgen's discovery he set to work, and by nightfall had succeeded in producing what was probably the first α -ray photograph taken in this country. The outbreak of war, Professor Rutherford said, had caused an almost complete stoppage in the great tide of advance in pure science, but the lull afforded a suitable opportunity for looking back with some degree of perspective over the ground covered during the last twenty years. Undoubtedly the discovery of this new type of radiation marked the beginning of an epoch in physical science and had brought about a revolution in ideas of the nature of matter and electricity almost as marked as that produced in biology by the theory of evolution. The two decades from 1895 to 1915 had been a period of pioneer advance over a new and fertile territory, with the almost daily discovery of interesting facts and the gradual unfolding of fundamental ideas. The directions of advance which had been stimulated by the discovery of α rays included investigation on the ionization of gases, electrons, the diffraction of α rays by crystals, and, most important of all, the phenomena of radioactivity, which was an even more direct consequence of the discovery of α rays than the work on the electron. The sequence of changes in uranium, radium, thorium, and actinium had now been followed out, not indeed completely, but in the main part. No doubt there would still be in the future considerable developments as the result of investigations of the multiple transformations of the atom, but as a whole, apart from a few outstanding difficulties, like the origin of actinium, the transformation of radioactive bodies was fairly well understood. A fundamental discovery, which had been completely verified just before the investigation was broken off by the war, was that certain radioactive elements were inseparable from one another—mesothorium and radium, for example—and this opened up a conception which must of necessity exercise a profound influence on all work on atomic weights, and lead to a close examination as to whether any of the ordinary elements were a mixture of "isotopes." Professor Rutherford went on to refer to the titanic violence of the explosion in the radioactive atom, shown by the expulsion of a particles at great speed and the ejection of electrons with nearly the velocity of light, accompanied by intense α rays of much greater penetrating power than any that could be excited by an α -ray tube. He believed that there was very little hope at present of obtaining tubes which could compete with radium or thorium in providing a source of α rays of very short wave length (and accordingly of great penetrating power). The γ rays of radioactive substances had proved to be of much shorter wave length than was previously supposed.

THE VALUE OF THE WASSERMANN REACTION.

When the complement deviation test devised by Bordet was applied to syphilis by Wassermann, Neisser, and Bruck it was received with enthusiasm as a method which would remove all difficulties in the diagnosis of this disease. Unfortunately this contributed to the exaltation of laboratory diagnosis at the expense of clinical experience—a state of affairs which persisted even after it was shown that the reaction was not a true antigen-antibody phenomenon, that it was not absolutely specific, that it was not always obtained in cases with clinical evidence of syphilis, and that it did not necessarily prove that the lesion under consideration was syphilitic. The Wassermann reaction, like other laboratory tests, is a valuable aid to the clinician, but a diagnosis based on the

evidence of this reaction alone is open to many sources of error. Some instances will be found in a memorandum on the subject at p. 427. A comparison of the *post-mortem* findings, with the results of the Wassermann reaction during life, carried out on 331 cases at the Bellevue Hospital, New York, by Symmers, Darlington, and Bittman,¹ is of interest. In 204 cases the results corresponded, one or both antigens (cholesterinized and alcoholic) giving a negative reaction, and no signs of syphilis being found at necropsy. In the remaining cases, however, the reaction was positive in about 30 per cent. in which no *post-mortem* signs of syphilis were found, and negative in 31 to 56 per cent. (depending on the antigen used) with characteristic *post-mortem* signs of syphilis. In more than half of the latter cases the lesions are described as active, the remainder being indolent or healed. The value of these results is diminished by the fact that naked-eye changes alone were depended upon, no microscopic examinations being made. It is quite possible for syphilis to be present without changes visible to the naked eye. The converse category of cases, in which the reaction was negative during life, but signs of syphilis were found after death, carries more weight; but here again the results are incomplete, for the period that elapsed between the Wassermann tests and the deaths is not stated, nor is the cause of the deaths stated. Owing to these omissions, the results of this research cannot be accepted as conclusive, although it indicates that syphilis may be found after death where the Wassermann reaction was negative during life.

THE AMERICAN MEDICAL RESERVE CORPS.

SUNDAY last (April 7th) was the first anniversary of America's entry into the conflict, and the official statement put out as to what has been accomplished in the year contains a number of interesting figures. A year ago the army numbered 212,000; it now numbers 1,650,000. The navy's strength a year ago was 82,700; to-day it is 351,000. The number of medical men who have passed through the army medical training schools is 6,000, which is at the rate of about 4.2 per 1,000 newly enlisted men. The number of medical officers in the navy is 1,675, which is at the rate of 4.8 per 1,000. We cannot fail to admire the manner in which members of the medical profession in the United States have set themselves with enthusiasm to learn their new specialty of military medical practice and administration. We gave some account last November of the three large training camps which were then in full swing. Their number has been increased, and recently in one camp in Georgia there were 1,500 doctors, and the energy they showed in the work was very satisfactory. In addition to instruction in purely military duties, refresher courses in all branches of medicine and surgery specially applicable to military life are given. The course through which each cadet officer passes lasts three months, and he is at work for about eight hours a day. During the first month he learns the ordinary work of the enlisted man of the Medical Department, so that he may be fitted for duty as an instructor; the second month is given to the special duties of medical officers as such, and the third to instruction in work in the field, such as the conduct of ambulance companies and field hospitals. In addition selected officers are sent for special training to laboratories for instruction in bacteriology and x-ray work.

FATS AND OILS IN B.P. PREPARATIONS.

THE General Medical Council has now announced the alterations and amendments to the *British Pharmacopoeia* 1914, which, as mentioned three weeks ago, the President was authorized to make in consultation with the Pharmacopoeia Committee in response to representations from the Food Controller and the Home Office

Committee on Drug Supply with regard to the necessity for discontinuing the use of various edible fats and oils in the official preparations. The following preparations are withdrawn until further notice: *Linimentum camphorae*, *linimentum chloroformi*, *linimentum hydrargyri*, *linimentum terebinthinae aceticum*, *liquor cresol saponatus*. In the United Kingdom certain specified substitutes for prepared lard and prepared suet may be employed in making official preparations; arachis (pea-nut) oil or sesame oil may be substituted for olive oil in official liniments, ointments, plasters, and soaps; and the use of the modified castor oil of commerce commonly known as "neutralized seconds castor oil" is permitted in making the official preparations for which castor-oil is directed to be used.

We are glad to learn that Lieut.-General Sir Arthur Sloggett, D.G., A.M.S., has received news that his only son, Lieut.-Colonel A. J. H. Sloggett, D.S.O., Rifle Brigade, who had been presumed killed, is alive and a prisoner at Karlsruhe. Colonel Sloggett was in command of a battalion of the Rifle Brigade which on March 21st was known to have been carrying on a desperate fight in holding up a German division, and had been reported missing.

Medical Notes in Parliament.

Military Service Bill.

Premier's Review of the Present Battle.—The New Proposals for more Man Power.—Provisions Affecting Medical Men.

MR. LLOYD GEORGE on April 9th introduced the new (third) Military Service Bill in the House of Commons with a grave and compendious statement of the situation.

He devoted a large part of his speech to a review of the war events in France during the past fortnight. At the beginning of the German great offensive the combatant strength of the whole of the German army on the Western front was, he said, approximately equal, but not quite, to the total combatant strength of the allies. In several respects the Germans were inferior, but they had several important advantages. One was the initiative, which gave a large margin to surprise, in spite of our superiority in the air. They had the very great advantage, further, of having a united command. Incidentally, too, they had an important advantage in the weather. It was dry and misty. Thus the attack succeeded where in ordinary spring conditions the ground would have been almost impossible; the warmth increased the mist, and thus they were able in some parts to come within a few yards of our lines before their approach became known. After a eulogy of the splendid services of the French reserves, and after a warm tribute to the valour of our army, Mr. Lloyd George referred to the measures adopted by the Cabinet to meet the emergency. No such large numbers of men had ever before crossed the Channel in so short a time. The Ministry of Munitions had replaced lost guns and ammunition, and still had a very substantial reserve. The number of our aircraft, too, was greater now than it was before the battle. Secondly, President Wilson without the smallest hesitation consented that the fighting strength of the American army should be immediately brought to bear on this struggle. Thirdly, the Premier called attention to the decision taken to secure unity of command—a decision which he assured the House had the fullest concurrence of all concerned.

The battle proved that the enemy had definitely decided to seek a military decision this year. There was still seven or eight months during which the fighting would continue, and everything depended upon keeping our strength to the end. With American aid we could do it, but even with that we could not feel secure unless the further sacrifices the Government proposed were made. The Premier acknowledged frankly the limitations—for use in the army—of the remaining man power in this country. He recognized also that the claims of the navy and of shipping must stand first, and that we had to supply coal largely to the allies as well as steel. There was still, however, a reserve of men to be obtained without impairing the striking power of the country for war.

¹ *Journ. Amer. Med. Assoc.*, February 2nd, 1918.

During the first quarter of this year there had already been raised for the armed forces more than that quarter's proportion of the original number of men estimated as the minimum required for the present year. There had been also a very strict comb out of some of the essential industries. Very large levies had been taken from the munition works; they would amount, he thought, to something like 100,000 Grade 1 men. That had been done this year. A call for 50,000 had been made on the coal industry and these men were being rapidly recruited; a call for another 50,000 men was to be made from this industry. It was proposed that no fit men below the age of 25 should be retained in the Civil Services; that would be a clean cut. Beyond that there would be a comb out. The clean cut was also to be applied to other industries in another way. Under the Act passed in January this year orders would be issued cancelling all occupational exceptions by age blocks in specified occupations. That would be a clean cut. The first of these orders was being laid on the table that day and other orders would follow. As it was necessary not only to have men but to have them quickly, the Government had shortened the length of the calling up notice from fourteen days to seven, and had authorized the serving of the notice by whatever method was most convenient. It might be necessary even to curtail right to appeal on medical grounds, but for the moment it was not proposed to do this. There had been a great many frivolous appeals which had wasted much time, and if that went on it would be absolutely necessary in the interests of the country that the right to appeal should be curtailed in this respect. There was another consideration: the strain upon the medical profession had been great already. They were very short of medical men, and they might be driven to take the course he mentioned for the hard necessities of the case.

Then the Premier brought the House to the new proposals actually embodied in the new bill. The first was to raise the military age to 50, with powers to raise it in special specified cases to 55. That last provision was to apply only where men with special qualifications were needed. For instance, it might be necessary to do this in the case of medical men. The raising of the age to 50 did not mean that men between 42 and 50 were necessarily to be put into the fighting line. It might be that there were men of that age just as fit as men of 55, but that would be the exception. There were a good many services in the army, however, which did not require the best physical material, and it would be very helpful to get men of this age in order to release younger and fitter men to enter the fighting line. They had also to prepare for home defence, so as to be able to release men from this country, and to fill their places by men between 42 and 50. The proportion of men from 42 to 50 that it was expected would be available for the line was not very high—something like 7 per cent. Only a small percentage of the men within the years named would be likely to come under the provisions of the Bill.

The next consideration was the question of exemptions. Under the Act passed this year the Minister of National Service already had power to cancel certificates granted on occupational grounds. It was proposed to make free use of this power, and several of these exemptions would be cancelled (under power already conferred on the National Service Ministry) by means of proclamation. This was another means of arriving at the clean cut. Any existing exemptions granted to such men would be superseded, and the men would be taken or left on medical grounds only. The provision would not be used to set aside pledges given to discharged soldiers. It was further proposed in the bill to take power by Order in Council both to reconstitute the tribunals and to regulate the areas in which they should work; to standardize the grounds of exemption and limit the rights of appeal. The areas within which tribunals might act would be reconsidered and in some cases adjusted. Local tribunals, like the appeal tribunals, would become nominated bodies and would be reduced in size, but existing members of tribunals who had rendered admirable service would be retained, and the tribunal staff and officers would be preserved. Touching the inclusion of ministers of religion in the bill for non-combatant purposes, Mr. Lloyd George said there was a shortage of fit men for the service of the sick and wounded, and he thought that ministers would be able especially to render services of this kind in the battlefield.

Finally, the Prime Minister stated the reasons for including Ireland in the scope of the bill. The point he made most emphatically was that it would be indefensible to ask young men of 18½ years of age and men up to 50 in England, Scotland, and Wales to fight whilst young men of 20 to 25 in Ireland were under no obligation to take up arms for the common cause. But as there was no

machinery in existence for applying the measure to Ireland and no register had been completed, it might take some weeks before actual enrolment began. Meanwhile it was intended to ask Parliament to pass a measure for self-government in Ireland. He wished it to be understood, however, that each question must be taken on its merits. While speaking on this matter Mr. Lloyd George was challenged by Mr. Devlin as to whether he was aware of the recommendation of the Irish Convention on this subject. The point of Mr. Devlin's interruption, which he brought out later, was that a Subcommittee of the Convention, consisting of the Duke of Abercorn, Lord Desart, Mr. Powell (three Unionists), and Captain Gwynn and Captain Doran (two Nationalist members who were soldier members of the Convention), had reported that it would be impracticable to enforce conscription in Ireland except with the approval of the Irish Parliament, and that the Convention had adopted this view as part of their report. Mr. Lloyd George said that he understood that the Convention reported by a majority, and the Government would have to accept responsibility of submitting to Parliament, with such guidance as the Convention report afforded, such proposals as it thought could be carried without violent controversy. In the subsequent debate Mr. Asquith spoke very gravely of the military situation, but with confidence in the army and the country's patriotism. He suggested that with the object of getting legislation in a form that would meet reasonable objections, a little more time than had been suggested should be given for the consideration of the bill.

Irish Nationalist members spoke in hostility to the inclusion of Ireland in the measure. Sir Edward Carson, on the other hand, expressed his pleasure that Ireland would be called upon to give her due share to the military forces. The Nationalists challenged division on the first reading, which was carried by 299 votes to 80, a minority almost exclusively composed of Nationalists.

In the second reading debate on April 10th Sir Donald Maclean, Chairman of the London Appeal Tribunal, gave the reasons why he and his colleagues held that it would not pay to raise the age beyond 48. The men between 39 and 41 who had come up lately, had been mostly subjected to grading under the new medical system. In the great majority of cases men graded A or Grade 2, had, on this medical test, been brought down to Grade 3. He assumed it was not intended to lower the medical standard. On such experience his belief was that not more than 3 per cent. of the men above 48 would have military value. This would mean a fresh avalanche of Grade 3 men, mostly unfit. Soldiers resented more the entrance of the unfit into the army, and commercial interests would suffer seriously without advantage to the country. Then, too, having regard to the real shortage of doctors, it should be remembered that this type of men would carry a much larger percentage of sickness and add to their difficulties. The Minister for National Service would agree that the result of the experience for the last two years was to show that sickness casualties among men between 35 and 41 were two and a half times greater than the casualties of men between 35 and 41. The businesses of these men would be paralysed to get slight returns. In the opinion of himself and his colleagues to raise the age so high would mean adding to the pension list materially, ruining physically thousands of men, and burdening the army unnecessarily. Later in the evening Mr. Asquith supported this view. He thought it undesirable also that there should be a contingent power for the executive without any reference to Parliament to raise the military age to 56. It would place many business men in great uncertainty. Mr. Bonar Law in his reply announced that the decision of the Government to apply conscription to Ireland was definite. He promised careful consideration to the question of the age limit as regards the high years. The test of the War Cabinet would be a necessity. Mr. Law emphasized the gravity of the situation. Sir Auckland Geddes, in winding up the debate for the Government, said that Clause 3, whereby it was intended to make clean cuts, was really the most important part of the bill. It was necessary to have all the resources which under the bill it was proposed to use.

The second reading was carried by 323 votes to 100, the minority being mainly composed of Nationalist members.

The first clause of the bill fixes the age of compulsory military service at from 18 to 51, subject to provisos as follows:

(a) If it appears to His Majesty at any time that it is necessary so to do for the defence of the realm, His Majesty may by Order in Council declare that the foregoing provision shall, as respects men generally, or as respects any class of men, have effect, as from a date to be specified in the Order, as if any age specified in

the Order not exceeding fifty-six years were therein substituted for the age of fifty-one years; and

(b) As respects any person being a duly qualified medical practitioner, the foregoing provision shall have effect as if the age of fifty-six years were therein substituted for the age of fifty-one years.

Clause 2 gives power to declare by proclamation that a national emergency has arisen, and that any certificates of exemption to any class or body of men shall cease to have effect. Clause 4 provides for the constitution of tribunals and for the establishment of special tribunals, committees, or panels for dealing with particular classes of cases, for regulating and limiting the making of applications to such tribunals, and for determining the grounds on which applications, or any particular classes of applications, may be made, and the right of appeal.

THE WAR.

THE MEDICAL SERVICE IN THE FIFTH ARMY.

The object of the great German attack on March 21st and following days seems to have been to break through the point of junction between the extreme right, or southern end of the British forces and the extreme left, or north, of the French. The course of the battle from that date to March 26th can now be traced, and in the following brief account we follow an admirable summary by Commandant de Civrieux.¹

General Character of the Retreat.

The British 3rd and 5th Armies were on a line from the Scarpe, the river which runs due west from Arras towards Douai, on the north and the Oise, on which La Fère and Noyon are situated, on the south. The country between is traversed about midway by the River Somme; from Peronne to Amiens the Somme runs nearly due west, but in its course from St. Quentin to Peronne it makes a deep bend south through Ham. The junction between the 5th Army and the French was a point near La Fère, just north of the Somme. Opposed to them from north to south were the armies commanded by Prince Rupprecht of Bavaria, the Crown Prince, and Generals von Below, von Marwitz, von Kathan, and von Gontard. The attack was on a line of about 70 kilometres (about 43 miles). The preliminary bombardment began at 2 a.m. on March 21st; the German infantry attacked at 8 a.m. on the same day by massed waves. On the 21st and 22nd the British 5th army fell back to the line Peronne-Ham; the 3rd army maintained its position in great part, but on March 23rd conformed on its right to the retreat of the 5th army, retiring to the line Bapaume-Peronne. It was on this day that the French took over the right of the British 5th army. On March 24th the enemy got across the Somme to the south and north of Peronne, and the 5th army retired to the line Bapaume-Combles-Maurepas, but in the evening forced the enemy back over the Somme. Meanwhile the French, to the south, had generally kept their ground. On March 25th the Germans reached Nesle, Peronne, and Bapaume, and the 5th army retired again, the Germans continuing to push towards Amiens by the roads Bapaume-Albert, Nesle-Chaulnes. The French, who had stood north-east of Noyon, evacuated the town on that night; fighting in this region continued to be severe, but northward the British line was for the time left comparatively quiet. The general effect of the five days' fighting had been to force the British 5th army westward with an inclination north, with the result that a great part of its back areas was lost, and it is in such areas in the second line that casualty clearing stations and the machinery for the evacuation of the wounded from them to the base is established.

The Withdrawal of the C.C.S.

Further details which reach us this week bear out very closely the information we were able to give in our last issue with regard to the medical services, more particularly the forward casualty clearing stations, during the rapid retirement at the end of last month. The German attack was expected, and the more advanced clearing stations were moved back at once without much difficulty, but as

the other medical units arranged in series at varying distances behind became threatened under the rapid and sustained advance of the enemy, the difficulties of evacuating the wounded became increasingly great. One after another the clearing stations had to be evacuated; sometimes a unit, after opening up in a new site, was obliged to clear its patients at the end of forty-eight or even twenty-four hours, and then fall back itself, losing each time more of its equipment. Occasionally the last cases were got away whilst the infantry were preparing to make a stand in the clearing station grounds, with the field guns firing over their heads from new positions behind. In one or two instances a few desperate cases were left behind under the care of a medical officer and some orderlies, but even these were eventually moved to safety. Under such conditions deliberate surgery such as is practised when behind a more or less stationary line was out of the question; all that could be done was to dress and feed the patients and perform a few urgent operations, evacuation meanwhile proceeding by ambulance train, or car, and fresh cases accumulating in large numbers from the field ambulances. At some points the most that could be done was to establish an improvised collecting station beside the railway and load the patients on trains as they came up. There were moments when it seemed that it would be impossible to get all the wounded away, but in every instance this was accomplished successfully, though sometimes the lightest walking cases, through lack of transport, had to be marched to the rear. Notwithstanding every sort of difficulty no officer, sister, or man of the clearing station personnel was lost, nor was a single patient left behind by these units to fall into the enemy's hands.

The Field Ambulances.

More remarkable even than this was the fact that while the clearing stations were moving backwards the field ambulances were able to evacuate cases in a steady stream and without hitch all through; it is believed that no patients even in the field ambulances were taken prisoner during the retreat.

Such results leave no doubt as to the organizing ability and resourcefulness of those in charge of the medical arrangements throughout a most trying and anxious period. Although the battle went hard for our troops in a military sense, the medical services seem to have come magnificently through an ordeal which can only be compared with the retreat from Mons.

Sisters and Nurses.

The gallantry of the sisters during the evacuation and removal of the forward clearing stations was alluded to last week. One group of nurses, we learn, stood quietly beside the railway line whilst their station was being shelled, waiting for a train which might or might not succeed in reaching them; yet next day they were at work in a new place as though nothing had happened. The officers and men of the R.A.M.C. showed the courage, coolness, and devotion which were expected of them during such critical times.

WAR OFFICE STATEMENT.

The Secretary to the War Office has issued the following statement:

In the recent retirement on the Western front a number of medical units, such as casualty clearing stations, fell into the hands of the enemy. All the medical and nursing personnel of these units, and the patients, were safely evacuated, none being captured. The equipment and material were replaced immediately, and large reserve supplies have, in addition, been sent to France. All deficiencies in personnel, officers, nurses, and other ranks have been made good.

The Canadian and Australian medical authorities have generously come to our help by lending us medical officers and nurses.

It is regretted that in the process of evacuating casualty clearing stations a number of casualties occurred among the medical and nursing personnel. This was inevitable, as the units had to be cleared out at short notice, under, in many cases, heavy fire. A surgical team which had generously been lent to one of our casualty clearing stations by a Philadelphia hospital was heavily bombed, and two officers and one nurse were wounded.

The consulting surgeons of the administrative medical staff in France report that the care and attention which the wounded are receiving leaves nothing to be desired.

ARMY.

Killed in Action.

CAPTAIN J. W. ANDERSON, M.C., R.A.M.C.(T.F.).

Captain Jonas William Anderson, M.C., R.A.M.C.(T.F.), was killed in action during the recent fighting on the Somme. He was the son of Mr. D. C. Anderson, of Southport, and was educated at Liverpool University where he graduated M.B. and Ch.B. in 1898. After acting as house-surgeon of the Liverpool Royal Infirmary, and of Southport Infirmary, and as surgeon of H.M. transport *Orotava* during the South African war (medal), he went into practice at Llanfair Caereinion, Montgomeryshire. He took a commission as lieutenant and medical officer in the 4th Territorial (Denbighshire) Battalion of the Royal Welsh Fusiliers on March 24th, 1906, was called out for service on September 3rd, 1914, and promoted to captain after six months' service. He received the Military Cross on January 14th, 1916.

CAPTAIN H. W. BATCHELOR, R.A.M.C.

Captain Henry Washington Batchelor, R.A.M.C., was killed in action on March 24th, aged 30. He was the eldest son of the late Dr. H. T. Batchelor, of Queenstown, South Africa, and was educated at the London Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1912. After filling the posts of clinical assistant in the cardiac department at the London Hospital and of assistant house-surgeon at the Poplar Hospital for Accidents, he took a temporary commission as lieutenant in the R.A.M.C. on August 7th, 1914, three days after war was declared, and was promoted to captain after a year's service.

CAPTAIN W. BROWNLIE, R.A.M.C.

Captain William Brownlie, R.A.M.C., was killed in action on March 25th. He was the youngest son of Mr. William Brownlie, of Invercargill, New Zealand, was educated at the Universities of New Zealand and Edinburgh, graduating M.A. and B.Sc. at the former, and M.B. and Ch.B. at the latter. He held a temporary commission in the R.A.M.C.

CAPTAIN D. C. CROLE, R.A.M.C.

Captain David Clement Crole, R.A.M.C., was killed in action on March 23rd, aged 33. He was the only surviving son of the late Dr. Angus Fletcher Crole of Leven, Fife, and was educated at Edinburgh University, where he graduated M.B. and Ch.B. in 1905. He held a temporary commission in the R.A.M.C. and was attached to the Hussars when killed.

CAPTAIN E. C. CUNNINGTON, R.A.M.C.

Captain Edward Charles Cunnington, R.A.M.C., was killed on March 23rd, aged 27. He was the only child of Captain B. H. Cunnington, Wiltshire Regiment, and was educated at Cambridge and at St. Bartholomew's Hospital, took the M.R.C.S. and L.R.C.P.Lond. in 1915, and held a temporary commission in the R.A.M.C.

CAPTAIN E. H. GRIFFIN, D.S.O., M.C., R.A.M.C.

Captain Ernest Harrison Griffin, D.S.O., M.C., R.A.M.C., was killed in action on March 21st. He was the only surviving son of the late Mr. John Griffin of Walsall, and was educated at Cambridge, where he graduated B.A. in 1898, and at St. Bartholomew's Hospital, taking the diploma of L.S.A. in 1902. He subsequently took the diploma in tropical medicine and hygiene at Cambridge in 1914. He had filled the posts of clinical assistant at the Samaritan Free Hospital, of assistant physician and pathologist at Camberwell House Asylum, and of surgeon to the Venezuela Goldfields; and served as surgeon to the British Red Crescent Society in Tripoli in the Turco-Italian war. He took a temporary commission as lieutenant in the R.A.M.C. on August 16th, 1916, and was promoted to captain after a year's service. He had been mentioned in dispatches, received the Military Cross on August 25th,

1916, and the D.S.O. on November 26th, 1917; and also held the Venezuelan Order of the Liberator.

CAPTAIN S. E. McCLATCHY, R.A.M.C.

Captain Samuel Edward McClatchey, R.A.M.C., was killed in action on March 25th. He was educated at Victoria University, Manchester, where he graduated M.B. and Ch.B. in 1911. After acting as junior house-surgeon at Preston Royal Infirmary, he went into practice at Buxton. He took a temporary commission as lieutenant in the R.A.M.C. on September 10th, 1914, was promoted to captain after a year's service, and was attached to the Welsh Regiment when killed.

CAPTAIN C. H. G. PHILP, R.A.M.C.

Captain Claude Hastings George Philp, R.A.M.C., was killed in action on March 26th, aged 32. He was educated at Cambridge, where he graduated B.A. in 1907 and M.B. and B.C. in 1912, and at St. Thomas's Hospital. After acting as assistant casualty officer at St. Thomas's and as resident medical officer of Herefordshire General Hospital, he went into practice at Hereford, where he held the appointment of honorary anaesthetist to that hospital. He joined the R.A.M.C. as a temporary lieutenant in 1916, and was promoted to captain after a year's service. He was attached to the Manchester Regiment when killed.

Died of Wounds.

CAPTAIN F. SIMPSON, R.A.M.C.

Captain Frederic Simpson, R.A.M.C., died at Templeton House, Roehampton, on March 31st, of wounds received on January 1st, aged 33. He was the second son of Mr. Sidney Simpson of Erith. He took a temporary commission in the R.A.M.C. in the middle of 1916, and was promoted to captain after a year's service. He received his medical education at Charing Cross Medical School, and took the diploma of L.M.S.S.A., and immediately after received a commission in the R.A.M.C.

CAPTAIN H. H. TAYLOR, R.A.M.C.

Captain Herbert Hampden Taylor, R.A.M.C., died of wounds in a Canadian stationary hospital on April 3rd, aged 35. He was the third son of the late Mr. Robert Taylor, solicitor, of Bedford Row, and was educated at St. Mary's Hospital, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1907, and at Cambridge, where he graduated M.B. and B.C. in 1908; after which he acted as house-physician and house-surgeon at St. Mary's Hospital, and as assistant medical officer at St. George's Infirmary. He took a temporary commission as lieutenant in the R.A.M.C. on April 24th, 1915, and was promoted to captain after a year's service.

CAPTAIN G. H. D. WEBB, R.A.M.C.(T.F.).

Captain George Harvey Duder Webb, R.A.M.C.(T.F.), died of wounds on March 29th. He was the second son of Mr. J. Collier Webb, and was educated at University College Hospital, London, taking the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1914. He took a commission as lieutenant in the 3rd London General Hospital on August 20th, 1914, and was promoted to captain after a year's service.

Accidentally Killed.

CAPTAIN T. L. ENRIGHT, R.A.M.C.

Captain Thomas Louis Enright, R.A.M.C., was accidentally killed recently at Salonica. He was the third son of Mr. James Enright, of Listowel, and took the diplomas of L.R.C.S. and L.R.C.P.Irel. in 1914. He joined the R.A.M.C. as a temporary lieutenant on February 1st, 1915, and was promoted to captain on completion of a year's service.

Died on Service.

LIEUT.-COLONEL R. BIRD, C.I.E., M.V.O., I.M.S.

Lieut.-Colonel Robert Bird, Bengal Medical Service, died at Wellington, Nilgiri Hills, Southern India, on March 30th, aged 51. He was born on December 4th, 1866, educated at St. Bartholomew's Hospital, and took the diplomas of M.R.C.S. and L.R.C.P.Lond. in 1888, the M.B. and B.S.Lond. in the same year, with honours in physiology, materia medica, and organic chemistry at the intermediate examination, the M.D. in 1889 and the M.S. in 1891, and also the F.R.C.S. and the D.P.H.Camb. in 1891. Entering the I.M.S. as surgeon on July 28th, 1891, he

became major on July 28th, 1903, and lieutenant-colonel on July 28th, 1911. After three years in the army he was posted in September, 1894, to civil employ in Bengal, where he spent the rest of his service. From March, 1895, to September, 1903, he was resident medical officer of the Calcutta Medical College Hospital, and in May, 1908, was appointed professor of surgery. Some fourteen years ago he was deputed on special duty to Kabul to treat the Amir of Afghanistan for an injury, and in the winter of 1911-12 was on special duty on the staff of the King-Emperor during his visit to India for the Coronation Durbar. He received the C.I.E. on January 1st, 1905, and the M.V.O. on January 4th, 1912.

Wounded.

Colonel A. D. Sharp, C.B., C.M.G., R.A.M.C.(T.F.).
Lient.-Colonel H. E. Fawcus, D.S.O., C.M.G., R.A.M.C.
Lient.-Colonel J. McMillan, M.C., R.A.M.C.(T.F.).
Lient.-Colonel R. T. C. Robertson, D.S.O., R.A.M.C.(S.R.).
Captain G. S. Clancy, R.A.M.C. (temporary).
Captain P. E. Earnshaw, Australian A.M.C.
Captain E. C. T. Emerson, R.A.M.C.(T.F.).
Captain H. L. G. Hughes, D.S.O., R.A.M.C. (temporary).
Captain J. W. Hunt, Canadian A.M.C.
Captain W. J. Knight, M.C., R.A.M.C. (temporary).
Captain W. F. Maclean, R.A.M.C.(S.R.).
Captain V. H. Mason, M.C., R.A.M.C. (temporary).
Captain S. A. W. Munro, R.A.M.C. (temporary).
Captain P. J. O'Shea, Australian A.M.C.
Captain F. E. L. Phillips, R.A.M.C. (temporary).
Captain R. N. Porritt, R.A.M.C. (temporary).
Captain H. E. S. Richards, R.A.M.C. (temporary).
Captain R. S. Ross, R.A.M.C. (temporary).
Captain T. J. Ryan, R.A.M.C. (temporary).
Captain L. M. Webber, R.A.M.C. (temporary).
Lieutenant H. Daw, R.A.M.C. (temporary).

Missing.

Major J. S. McConnachie, R.A.M.C.(T.F.).
Captain M. T. Ascough, M.C., R.A.M.C.(T.F.).
Captain T. E. H. Carr, R.A.M.C. (temporary).
Captain W. M. Christie, R.A.M.C. (temporary).
Captain P. P. Corbett, R.A.M.C.(S.R.).
Captain S. Cross, R.A.M.C. (temporary).
Captain C. E. P. Husband, R.A.M.C. (temporary).
Captain G. R. Lipp, R.A.M.C. (temporary).
Captain A. T. I. MacDonald, R.A.M.C. (temporary).
Captain D. Macnair, R.A.M.C.(T.F.).
Captain C. Mearns, R.A.M.C.(T.F.).
Captain E. J. Storer, R.A.M.C. (temporary).
Captain G. Torrance, R.A.M.C. (temporary).
Captain D. A. Wilson, R.A.M.C. (temporary).
Lieutenant W. H. Rawdon, R.A.M.C. (temporary).

DEATHS OF SONS OF MEDICAL MEN.

Barton, John Francis Sinclair, Sublieutenant R.N., youngest son of Dr. F. Alexander Barton, killed March 13th, aged 24.

Glendinning, James Graham, Second Lieutenant Monmouthshire Regiment, attached Royal Flying Corps, only son of Dr. Glendinning, late medical superintendent Monmouthshire Asylum, Abergavenny, killed in action in France on December 2nd, 1917, aged 20. He was educated at King Henry VIII's Grammar School, Abergavenny, and at Epsom College, where he keenly interested himself in sports, winning the MacFarlane Cup for his House in 1916 and the Blande prize. He was Head Prefect for his House, and had just begun medical studies when he joined the Monmouthshire Regiment in July, 1916.

Cummins, Thomas Coote, Second Lieutenant York and Lancs Regiment, only son of Dr. Wm. MacAlister Cummins, of Renishaw, Chesterfield, killed in action on March 25th, 1918, aged 19. He was educated at Chesterfield Grammar School, and King Edward VII School, Sheffield, and was about to enter Sheffield University when he was called to his military duties. He received his commission in September, 1917, and proceeded to France on November 4th, 1917.

Hall, Wilfred Rodenhurst, M.C., Lieutenant Suffolk Regiment, fourth and youngest son of Dr. H. S. W. Hall, of Hertford, killed March 27th, aged 20.

Haynes, John Eustace Tarleton, Second Lieutenant 1st Worcestershire Regiment, killed in action on March 23rd, only child of Dr. and Mrs. Sydney Haynes of Edgbaston, aged 19. He was educated at the West House School, Edgbaston, Berkhamsted, and Sandhurst, and got his commission in May, 1917. Both his grandfathers were medical practitioners.

Mackintosh, Ian Keith, Second Lieutenant Black Watch, only son of the late Dr. W. A. Mackintosh of Montrose, killed March 21st.

O'Keeffe, Marcus Manus, M.C., Captain Royal Field Artillery, only son of Major-General M. W. O'Keeffe, M.D., C.B., D.M.S. 4th Army, killed April 2nd, aged 21. He was educated at Cheltenham College, got his commission on February 10th, 1915, and gained the Military Cross in July, 1916.

Purdy, R. G., Major New Zealand Military Forces, was killed in action, together with his Brigadier-General, by the bursting of a shell. Major Purdy was the son of Colonel J. R. Purdy, M.B., C.M.Aberd., D.M.S. New Zealand Army, nephew of Colonel J. S. Purdy, commanding the Third Australian General Hospital, and a grandson of Captain Johnbarns, of Aberdeen, an officer with a distinguished record in the Crimea and Indian Mutiny. He was educated at Wellington College, New Zealand, and entered the New Zealand Permanent Defence Force in 1912. He had received the Military Cross and bar, and the Croix de Guerre. He married shortly before leaving for the war, and his widow survives him.

Skrimshire, Herbert Eric, Second Lieutenant Royal Garrison Artillery, younger son of the late Dr. Skrimshire of Morpeth, died of wounds on March 29th, aged 27.

Willans, Alan James, Captain King's Royal Rifle Corps, youngest son of the late Dr. Willans of Much Hadham, Herts, killed on March 24th, aged 21.

MEDICAL STUDENT.

Scott, Harvey Alexander, Lieutenant Gordon Highlanders, son of the Rev. Thomas Harvey of Edinburgh, died of wounds at a casualty clearing station on March 29th, aged 21. He was educated at Daniel Stewart's College and at Edinburgh University, where he was a medical student before the war. He got his commission from the O.T.C. on January 8th, 1916, and had twice previously been wounded.

[We shall be indebted to relatives of those who are killed in action or die in the war for information which will enable us to make these notes as complete and accurate as possible.]

HONOURS.

A SUPPLEMENT to the *London Gazette*, published on April 6th, contained statements of the services for which the decorations announced in the *Gazette* of November 26th, 1917 (BRITISH MEDICAL JOURNAL, December 1st, 1917, p. 738), were conferred. The following officers of the medical services received the awards indicated "for conspicuous gallantry and devotion to duty":

Bar to the Distinguished Service Order.

Major (temporary Lieut.-Colonel) Patrick John Hanafin, D.S.O., R.A.M.C.

For nine days he was continuously under heavy shell fire while supervising the evacuation of the wounded in the most adverse circumstances. Finally, although wounded in passing through a heavy barrage, he continued on duty until the last man had been brought in. The successful evacuation of the wounded was largely due to his gallant conduct.

Temporary Captain Robert McCowan Hill, D.S.O., R.A.M.C.

While on the way to battalion headquarters his party was caught in an enemy barrage, and four of them were wounded. He at once dressed their wounds on the spot in a most exposed position and under heavy fire. On arriving at the aid post he was informed that a whole machine-gun team were casualties in an advanced position. No stretcher-bearers were available, and he at once went forward and attended to them on the spot under heavy fire. He then returned and worked at his aid post under intense shelling, often attending to cases in the trench outside when the aid post was full. Casualties were being caused all round him, and he was wounded himself, but, though suffering severely, he remained at duty for sixteen hours until the battalion was relieved. He set a most inspiring example of courage and devotion to duty to all ranks.

Distinguished Service Order.

Major William Bannerman Craig, A.A.M.C.

After the aid post had been blown up during an attack, he attended the wounded and organized bearer parties in the open. Though wounded he persisted in his work until disabled by another wound.

Temporary Captain James Churchill Dunn, M.C., R.A.M.C.

He worked with untiring energy in the open in the front line, searching for and dressing the wounded and constantly exposing himself to machine-gun and rifle fire. His medical orderlies were both wounded, and the greater portion of his work was done without any assistance. He set a magnificent example to all of courage and devotion to duty under continuous heavy fire and enemy counter attacks.

Temporary Captain Ernest Harrison Griffin, M.C., R.A.M.C. (killed in action, March 21st).

He established his dressing station well forward during an attack, and went up to the front line through a storm of artillery and machine-gun fire utterly regardless of personal safety. He moved about in the open for thirty-six hours without food or rest, attending to the wounded, often leading parties of bearers through heavy barrages until every wounded man had been carried back. He remained behind after the battalion was relieved, still searching for wounded, under heavy fire, though he was several times badly shaken by the explosion of shells. He set a most inspiring example of courage and devotion to duty.

Major William Allan Hailes, A.A.M.C.

His example in attending to four wounded men in the open under heavy fire and conveying them to cover stimulated the stretcher-bearers to great efforts under most trying circumstances.

Major Harrie Bertie Lee, M.C., A.A.M.C.

He was in charge of the organization of bearer reliefs during an action, and hearing that the officer in charge of the forward bearer parties had been killed he at once went forward under heavy fire

and took charge. He located the new regimental aid posts forward of the former front line, and with absolute disregard of danger arranged for the evacuation of the wounded from these new posts through a heavy barrage. His quick grasp of the situation and prompt and courageous action were of inestimable value.

Major Kenneth MacCormick, C.A.M.C.

When in charge of the evacuation of the wounded during an action he remained at duty for forty-eight hours without rest, visiting the advanced posts, searching shell holes and bringing in many wounded. When one of his bearer posts was heavily shelled, with great coolness he got all the wounded away, staying behind himself until the last had left. He set a splendid example of courage and untiring energy.

Major Robert Maxwell McMaster, A.A.M.C.

He tended the wounded continuously for ten hours under shell fire. Several of his bearers were killed and wounded, and it was only with the greatest difficulty that he was able to save the wounded from being killed or buried alive.

Captain and Brevet Major Henry Forbes Pantou, M.C., R.A.M.C.

The evacuation of casualties, amounting to 60 officers and 1,100 men, after an advance of 3,000 yards was most successfully carried out, chiefly owing to the initiative and sound judgement displayed by him. He spent twenty-four hours in the forward area, visiting every regimental aid post and sending back hourly reports until the battlefield was completely cleared of wounded.

Bar to the Military Cross.

Temporary Captain William Thomson Brown, M.C., R.A.M.C.

He acted as bearer officer during an action, and was continuously in the open under heavy fire of all kinds. Though several times blown up by shells he remained at work, and set a most inspiring example of courage and gallantry.

Temporary Lieutenant (temporary Captain) Henry Alphonsus Harbison, M.C., R.A.M.C.

He was in charge of divisional stretcher-bearers during several days' operations. For seventy-two hours he never slept, and was continually on the move under intense shell fire, establishing connexion with the regimental aid posts and leading and directing the bearers. The entire success of the evacuation of stretcher cases from the forward area was due to his magnificent example. His coolness, courage, and endurance had a wonderful influence on his bearers. He has rendered conspicuous and valuable service on many other occasions.

Temporary Captain Reginald Ralston Huxtable, M.C., R.A.M.C.

This officer worked for three days and nights under the most appalling conditions helping the wounded, being continually in the greatest danger. He finally collapsed on reaching camp.

Captain Charles Herbert Leedman, M.C., A.A.M.C.

He worked for four days in the open attending to the wounded, in the course of which he dressed 300 cases. Seven intense barrages were put down by the enemy, but he went on with his duties, showing a total disregard for danger. His courage, devotion to duty, and endurance greatly inspired all ranks, and undoubtedly saved many lives.

Captain George Reginald Edward Gray Mackay, M.C., R.A.M.C.

He personally supervised the evacuation of the wounded, making several journeys through a heavy barrage. On many previous occasions he has performed similar acts of gallantry.

Temporary Captain Charles Joseph O'Reilly, M.C., R.A.M.C.

He personally supervised the evacuation of wounded, passing and repassing through heavy barrage fire. When a neighbouring M.O. was killed, he attached himself to the battalion and dressed and supervised the evacuation of the wounded.

Captain Patrick Joseph Francis O'Shea, M.C., A.A.M.C.

He dressed the wounded in the open after the aid post had become congested, and organized stretcher parties under heavy fire. His resource and courage saved many lives. He afterwards went round the shell holes with a party of bearers, dressing and collecting the wounded with a fine disregard of personal danger.

Temporary Captain John Finlayson McGill Sloan, M.C., R.A.M.C.

He worked continuously for two days, dressing over 150 cases in the open under heavy fire, three or four of the wounded being hit by snipers. He showed a fine example of coolness and sense of duty.

Temporary Captain Gideon Walker, M.C., R.A.M.C.

He worked for twenty-four hours after an attack in an advanced area, getting in the wounded of two battalions, and remained in the line after his own battalion was relieved. He showed the greatest contempt of danger under heavy shell fire.

(To be continued.)

The Sultan of Egypt has conferred the Order of the Nile (4th Class) upon Captains William Edward Marshall, M.C., and William Hubert Milligan, both of the R.A.M.C., for distinguished services rendered during the course of the campaign.

The following are among the decorations conferred by the Allied Powers on officers and men of the British naval forces for distinguished services rendered during the war:

Croix de Guerre (conferred by the President of the French Republic): Surgeon Alfred G. Williams, R.N.

Order of the Rising Sun, 4th Class (conferred by the Emperor of Japan): Fleet Surgeon Samuel Conner, R.N.

Order of the Redeemer—Commander (conferred by the King of the Hellenes): Staff Surgeon Ernest D. Rutherford, R.N.

England and Wales.

CEREBRO-SPINAL FEVER IN 1916.

THE annual report of the Registrar-General for 1916 contains some statistics of the incidence of cerebro-spinal fever during that year. London and the South of England generally again suffered far more than the rest of the country as measured by the death-rates. The notification figures bring out very clearly the degree to which the disease specially affected the metropolitan area. The civil notifications from the county of London numbered 428, and from Croydon, West Ham, and East Ham 32. Two hundred more civil notifications came from Essex, Middlesex, Kent, and Surrey, making altogether 660 notifications from the London area out of 1,306 for the whole country. For the civil population the recorded case mortality rate amounted to 59 per cent., as against 53 in the previous year. It was lowest in London—52 per cent.—“as was perhaps to be expected in view of the fact that London practitioners have been officially instructed to notify cases of posterior basal meningitis, while no similar instruction has been issued elsewhere. If, in view of this fact, deaths from posterior basal meningitis are included in calculating the case-rate for London, it comes to 58 per cent., or nearly as high as elsewhere. The rate in the county boroughs was 61 per cent., in the smaller towns 63, and in the rural districts 60. These figures may have very little bearing upon the real fatality of the disease, as many slight cases are doubtless overlooked, and notified cases are not always confirmed on verification, but they do form some measure of the prospects of recovery of cases sufficiently typical to be recognized.” The deaths in the civil population showed a decline of 44 per cent., and the deaths of non-civilians (449 in number) were fewer by 26 per cent. than those of the previous year, but in the absence of a return of the military population these figures are largely meaningless. In 1916, as in 1915, the majority of the cases occurred in the first two quarters; 68 per cent. of the total deaths of the year were returned for the first half of 1916, as against 78 per cent. in 1915.

THE NEWCASTLE ORTHOPAEDIC CENTRE.

The Orthopaedic Centre at Newcastle-on-Tyne, to which the Army Council upon the representation of the Ministry of Pensions has arranged to make a grant of £10,000, will be an extension of the Royal Victoria Infirmary and will ultimately become part of that institution, but during the war it will be staffed by the military. Soldiers, both before their discharge and after they have become pensioners, will be treated there. After the war the Ministry of Pensions will have a claim upon the beds.

Ireland.

ENNISKILLEN GUARDIANS AND THEIR DOCTORS.

At a recent meeting of the Enniskillen board of guardians a letter was read from the Local Government Board stating that no steps seemed so far to have been taken by the guardians towards reinstating the dispensary medical staff or arranging for their resumption of duty; in face of the gravity of the situation, the Local Government Board again urged the guardians to place the doctors at once in charge of their districts and thereby make efficient provision for the medical care and treatment of the sick poor. The guardians by their resolutions and advertisements had admitted that the old salaries were inadequate, and the adoption of a new suitable scale was therefore unavoidable in present circumstances, and ought to be formulated as soon as possible and submitted for sanction. Letters were also read from Dr. T. Hennessy, Irish Medical Secretary of the British Medical Association, and from Dr. R. Marley Blake, President of the Irish Medical Association. Dr. E. Stephenson, Local Government Board Inspector, was present at the meeting of the guardians and asked them to appoint a committee to go into the matter. The guardians had exhausted their resources; they had tried everything to get doctors, but they had not adopted the most obvious plan—to go into

conference with the doctors. Although the doctors had acted a little hastily in resigning—they must forgive him for saying it—the guardians were not without blame in the matter. The salaries they had paid to their medical officers were altogether inadequate for the services rendered. The guardians themselves had since admitted that by offering a much larger remuneration when advertising for doctors to fill the vacancies of their former medical officers. The *Fermanagh Herald*, in an editorial article headed "The Poor Law Scandal," says that the action of the Enniskillen board of guardians in again ignoring the request of the Local Government Board to make immediate and efficient provision for the medical care and treatment of the sick poor in the union is a grave scandal, and is deserving of the condemnation of all classes of the community. For six weeks the union has been without dispensary doctors, and were it not for the kindness of the medical men who have voluntarily treated a number of serious cases free of charge, the deadlock would have been productive of serious, and perhaps tragic, results. Any one who has read the speeches made at the meetings of the board of guardians for the past few weeks must come to the conclusion that the attitude taken up by the majority of the members was actuated by a feeling of wounded pride and vanity, because the doctors tendered their resignations, and that no attempt was made to consider the question on its merits. On two previous occasions the medical officers applied for an increase of salary, and the facts stated by them in support of their claim could not be controverted, yet on both occasions the board derisively rejected their application.

Correspondence.

PRIMARY SUTURE OF WOUNDS.

SIR,—The paper by Sir Anthony Bowlby, in the *JOURNAL* of March 23rd, embodying as it does material of the highest possible value, should be widely read and carefully studied. Sir Anthony has had a unique opportunity of watching the work at the casualty clearing stations and of following the changes that have gradually come about in the treatment of wounds since the beginning of the war.

Evolution is usually so slow a process that all the steps of its advance can rarely come within the purview of a single generation. That of aseptic surgery—from Pasteur's discovery of the cause of putrefaction, through the genius, the unceasing labour, and the tireless energy which Lister brought to bear upon its application to the treatment of wounds—covered a period of many years. But during the war we have seen all the stages in the establishment of a vital principle taking place under our very eyes. It is, however, no new principle that has been evolved; it is nothing more than the vindication of aseptic surgery. I do not use the term in that narrow and trivial sense which distinguishes antiseptic and aseptic according to whether chemicals are or are not employed, as if there existed two different systems. No one who reads Sir Rickman Godlee's *Lord Lister* can fail to realize that Lister saw clearly the vital principle which underlies all modern surgical technique—namely, that if microbes could be excluded from wounds no suppuration would occur; that if their presence could not be altogether avoided, then the fewer there were the better chance would the tissues have of dealing with the infection. He realized that chemicals could so damage the tissues as to make them more vulnerable to microbic attack, and that foreign bodies were harmful in wounds which were not germ-free. The problem to which Lister chiefly devoted his attention was the exclusion of microbes from clean wounds, or the prophylactic treatment of wounds deliberately made by the surgeon. The technique built upon the foundation laid by Lister had reached a high, indeed, an almost perfect state of development by 1914, and what the respective advocates of "aseptic" and "antiseptic" surgery were disputing was really a matter not of principle, but of detail.

What surgeons were confronted with in 1914, however, was the problem of the already infected wound. Some, instead of seeking to vindicate the principles of aseptic

surgery under this supreme test, ransacked the chemists' shops in the vain endeavour to find some germicidal panacea. But whilst this was going on Sir Almroth Wright was demonstrating that it was to nature that we must look for the solution of the problem. The re-discovery of this fundamental principle came from the laboratory, and justice requires it to be acknowledged that once again the practical surgeon is indebted to the pathologist. Neither brilliant colours nor pungent odours can replace an efficient surgical technique.

Sir Almroth Wright told the surgeon to look to surgery and not to chemistry for the solution of the problems raised by the wounds of war. The advocates of the various antiseptics which have from time to time been put upon the market have themselves admitted the truth of this doctrine, the directions for their employment being almost invariably prefaced by the statement that the preliminary opening up and thorough cleansing of the wound, together with the removal of all foreign bodies and dead tissue, are essential for success. "Bipp" affords a good illustration. Here was an ointment compounded of paraffin, bismuth, and iodoform, which, placed in a wound, was to exercise a continuous antiseptic action during the healing process. Assuming such action to be possible, then the cleaner the wound can be got by mechanical means, the less paste will be required; and if the quantity used is an index of the state of the wound at the completion of the primary operation, it follows that those wounds must be the cleanest, and will heal best, from which the paste is altogether omitted. Moynihan¹ writes that: "It is almost certain that in the perfect mechanical cleaning of the wound lies the secret of the (Morrison's) method." The truth of this conclusion is established by the practical results which Sir Anthony Bowlby quotes. The greatest good that has resulted from this preparation, as well as from others, is a demonstration of the paramount importance of efficient surgery.

One of the points in Sir Anthony Bowlby's paper which calls for criticism is his opinion of the chronological order in which primary closure of wounds came to be employed. Colonel Gray was, I feel sure, advocating the excision and suturing of cranial wounds long before the closure of wounds of the knee-joint was being practised, and the following quotation from a paper by Harvey Cushing,² written after his experiences in France in 1915, has a bearing upon the question:

"What is," he writes, "of paramount importance is to make a most thorough exploration and repair at the first sitting, usually with a flap incision away from or circumscribing the wound. . . . This reflected flap of scalp should be accurately closed . . . in order to ensure primary healing with scalp protection for the denuded dura or brain; and if drainage is advisable, it should be from the distant angles of the wound. . . . This, I am aware, is quite contrary to the generally accepted method of local enlargement of the wound with subsequent direct drainage. . . . This principle of exploration through a distant or flap incision, with subsequent closure, has been put into practice by a number of the more successful operators."

Sir Anthony Bowlby says:

"Injuries" (that is, of the skull and brain) "which had been treated in the early days by drainage with bad results, were now treated by surgical excision and primary suture of the scalp with infinitely better results."

This would seem to throw the blame for early bad results upon the drainage, whereas in reality it was the lack of efficient surgical treatment at the primary operation which was responsible. From quite early days the closure of the scalp wound, after thorough surgical cleansing, was advocated both by Colonel Gray and myself (and later by Surgeon-General Wallace). The different plastic methods devised for procuring a whole scalp with which to close the cranio-cerebral wound, and the question of temporary distant drainage, are points of detail which do not affect the main proposition.—I am, etc.,

PERCY SARGENT,

London, W., April 3rd.

Lieut.-Colonel R.A.M.C.

REAMPUTATION.

SIR,—In the *BRITISH MEDICAL JOURNAL* of August 25th, 1917, a most interesting paper by Mr. W. Sampson Handley was published on a method of flapless amputation, with subcutaneous division of the bone at a higher level.

¹ American Addresses, 1917.

² *The Military Surgeon*, June, 1916.

The feature of the method was the division of the bone with a Gigli saw introduced subcutaneously. As the subcutaneous introduction of the saw proved difficult I have substituted for it an open introduction, and am now convinced that Mr. Handley's method thus modified will, if generally adopted, rob reamputation of all its terrors.

Previously I had always approached a reamputation with misgiving. There never was any satisfactory way of cutting off the necessary amount of bone to obtain flaps, and violent recrudescence of sepsis was always set up. In one case I was dividing the femur with a chisel, and when half through it the rest of the femur split up as far as the small trochanter, thereby tearing a perforating artery, haemorrhage from this on the following day requiring ligature of the common femoral.

By Mr. Handley's method the bone is got away with the greatest ease, without any risk of haemorrhage, and with a minimum of disturbance to the tissues, and consequently of sepsis. Instead of cutting back the flaps to get out the bone, he removes the bone to make the flaps, a revolutionary proceeding of inestimable value. Mr. Handley's method transforms a severe major operation into an almost trivial minor one.—I am, etc.,

London, W., Feb. 9th.

PAUL BERNARD ROTH.

THE NATURE OF THE RHEUMATIC POISONS.

SIR,—In a note on "The Variation in the Specific Gravity of Urine and its Relation to Disease" (*Lancet*, June, 1917), I endeavoured to show, as a result of twenty years' observation, that the rheumatism and chorea following scarlet fever and other infectious diseases are caused by the retention of katabolic toxins or tissue waste. I based my belief on the fact that the urine in these cases falls in specific gravity and continues in this condition long after the albumin, usually following scarlet fever, has disappeared: a circumstance plainly showing that the glomeruli, as indicated by the appearance and the early disappearance of albumin, have been the first to suffer injury from the toxins and high temperature of the preceding fever, and are the first to recover, but that the more lasting injury as shown by the continued low specific gravity of the urine has fallen upon those cells in the kidney—namely, the tubular epithelium—whose function it is to exert a selective activity on the blood and to eliminate the products or toxins of katabolism.

Much has been said of the absorption of tonsillar and dental toxins as a cause of rheumatism, chorea and cardiac troubles. It would, however, be scarcely an exaggeration to say that 25 per cent. of human beings are going about in apparent health with chronically disordered tonsils, the crypts frequently blocked with secretion in a high state of decomposition, and yet many of such cases suffer little inconvenience therefrom. But with regard to dental toxins, I am able to prove from my observations in examining recruits, that scarcely one in 500 is without one or more carious teeth, and that many cases with undoubtedly septic mouths show no symptoms whatever of rheumatic, cardiac, or nervous disease.

Rheumatism or its associates will, however, supervene so soon as the renal tubular epithelium is sufficiently injured by the absorption of tonsillar or any other toxin to lower its vitality, and thus hinder its action; the other conditions following as a consequence of the auto-intoxication resulting from the retention of the products of tissue waste: conditions which neither the tonsillar nor the dental toxin acting alone is of sufficient virulence to bring about. Otherwise, the latter poisons must exist in sufficient quantity to induce a state of sapraemia or septic intoxication, or be of such toxic intensity as to set up septic infection; but whether these poisons be sapraemic or septicæmic, they must of necessity lead to toxæmic conditions differing widely from the rheumatism resulting from the absorption of toxins from organs chronically diseased; the continued pale urine of low specific gravity constantly associated with rheumatism of this type pointing to an injured tubular epithelium and to the consequent retention of katabolic toxins as the cause of the rheumatism.—I am, etc.,

Liverpool, March 9th.

WILLIAM BRAMWELL.

Obituary.

ALFRED HENRY CARTER, M.D., M.Sc., F.R.C.P.,

EMERITUS PROFESSOR OF MEDICINE, BIRMINGHAM.

DR. A. H. CARTER, of Birmingham, well known beyond the borders of that city as the author of one of the best of the smaller textbooks of medicine, died at his residence, Abingdon, Berkshire, on April 4th.

He was born in 1849 at Pewsey, Wiltshire, where his father practised as a surgeon. He went to school at Epsom College, and received his medical education at University College, London. He took the diplomas of M.R.C.S. and L.S.A. in 1870, and at once volunteered for service with a field hospital during the Franco-German war. After his return he became house-physician at University College Hospital, and in 1871, the year in which he graduated M.B.Lond. with honours, was appointed house-physician to the General Hospital, Wolverhampton. In 1872 he took the degree of M.D.Lond., and his long connexion with Birmingham began with his appointment as pathologist to the General Hospital; he was afterwards house-physician to the same hospital. He took the diploma of M.R.C.P.Lond. in 1876, and was appointed assistant physician to the Birmingham Hospital for Sick Children; not long afterwards he became physician to the Queen's Hospital. He became a Fellow of the Royal College of Physicians in 1891, and gave the Ingleby lecture in Birmingham in 1893. He took a prominent part in bringing about the closer connexion of the medical faculty of Queen's College with Mason College, and while professor of physiology at the former institution helped materially to improve and widen the scope of the teaching. For more than thirty years he was busily engaged as a teacher of clinical medicine, and during the later years of his time at Birmingham was joint professor of medicine. Dr. Carter not only took a large part in the medical life of Birmingham, but a share also in the public affairs of the city, serving for a time on the city council, and as a member of its health committee.

He was long an active member of the British Medical Association. He was vice-president of the Section of Diseases of Children at the annual meeting at Leeds in 1889 and president of that section at the annual meetings in Birmingham in 1890 and 1911. He was president of the Birmingham Branch in 1895-96, and was at one time a member of the central Council. He was also president in 1896-97 of the Midland Medical Society. In 1901 he received the degree of M.Sc. from the University of Birmingham. He was J.P. for the county of Worcester and Lieutenant-Colonel R.A.M.C.(ret.).

He retired from practice in 1913, but when war broke out was anxious to do his share; for a time he acted as physician to the hospital established by Lady Norman at Wimereux. Afterwards he served in the hospital ships *Aquitania* and *Britannic* in the Mediterranean, and later was consulting physician at Tidworth for the troops on Salisbury Plain. He was twice mentioned in dispatches for valuable services. He had to relinquish his military work last June owing to a breakdown in health. Before he was taken ill last summer he had almost completed a valuable paper on cerebro-spinal fever founded on 93 interesting cases he had collected, but he was not able to complete his report.

We have already mentioned Dr. Carter's chief publication, the *Elements of Practical Medicine*, which reached a tenth edition in 1912. The book had the qualities which distinguished the author: it showed not only a wide acquaintance with medicine and physiology, but a well-balanced and orderly mind, which placed every fact in its logical sequence.

Dr. Carter was twice married and is survived by his second wife and a daughter. His younger son died of wounds received in Flanders in 1915, and his elder son died some time ago of illness.

The funeral took place at Abingdon on April 8th.

The death occurred on March 10th of Dr. PETER GALLOWAY, who had practised for the past seventeen years at Spalding. He received his medical education at the University of Aberdeen, graduating M.B., C.M. in 1881.

and practised for some years at Willingham, near Gainsborough. Dr. Galloway was a member of the Holland Division of the British Medical Association. He leaves a widow, one daughter, and one son, Dr. Norman Galloway, who is serving with the R.A.M.C. in British East Africa.

DR. GEORGE ROGER PARKER, the oldest medical practitioner in Lancaster, died on March 11th after a long illness. He was educated at the Royal Grammar School, Lancaster, and St. Bartholomew's Hospital. He took the diploma of M.R.C.S. in 1875 and that of L.R.C.P.Lond. in 1877. He held the post of M.O.H. for the borough and port of Lancaster from 1886 to 1910. He was the senior medical officer to the Royal Lancaster Infirmary, having been appointed thirty-six years ago, and was president of that institution in 1908. He leaves two sons, Captain G. M. Parker, Australian Medical Service, and James I. Parker, a sheep farmer in Australia, who is at present serving with the Australian Veterinary Corps at the front, also one daughter, the wife of Dr. W. A. Rail of Capetown.

AMONG the victims of the recent air raids on Padua was DR. ELIO DE AMBRIS, who continued the work of his master Lombroso. He was the author of treatises on degeneration and criminality.

Medical News.

THE maximum retail price of butter has been fixed in Paris at the equivalent of 4s. 2d. a lb.

A REVISED edition of Taylor's Tables for calculating weekly meat rations is published by Effingham Wilson, and can be obtained through booksellers, price 6d.

THE late Dr. Elizabeth Garrett Anderson left estate of the gross value of £24,098, the net personalty being £15,806.

ACCORDING to the latest estimate of the (American) National Association for the Study and Prevention of Tuberculosis, based largely on the results of the examination of recruits and drafted men for the new army, when about 2 per cent. of men of draft age in the country at large were found to be tuberculous, it is estimated that the number of active cases of tuberculosis in the United States is probably between two and three millions. At present 45,000 beds are available, but 50,000 more are needed.
